The increased risk for CAD is proportional to the degree of obesity. Obese persons may produce increased levels of LDLs and triglycerides, which are strongly related to atherosclerosis. Obesity is often associated with hypertension. There is also evidence that people who tend to store fat in the abdomen (an "apple" figure) rather than in the hips and buttocks (a "pear" figure) have a higher incidence of CAD (see Table 41-2). As obesity increases, the heart grows and uses more oxygen. In addition, there is an increase in insulin resistance in obese individuals.[2]

Contributing Modifiable Risk Factors

Diabetes Mellitus. The incidence of CAD is two to four times greater among persons who have diabetes, even those with well-controlled blood glucose levels, than the general population. The patient with diabetes manifests CAD not only more frequently but also at an earlier age.[2] There is no age difference between male or female patients with diabetes in the onset of symptoms of CAD. Diabetes virtually eliminates the lower incidence of CAD in premenopausal women.

Undiagnosed diabetes is frequently discovered at the time a person has an MI. The person with diabetes has an increased tendency toward endothelial dysfunction. This may account for the development of fatty streaks in these patients. Diabetic patients also have alterations in lipid metabolism and tend to have high cholesterol and triglyceride levels. Management of diabetes should include lifestyle changes and drug therapy to achieve a glycosylated hemoglobin (A1C or Hb A1C) level of less than 7%.[6]

Metabolic Syndrome. *Metabolic syndrome* refers to a cluster of risk factors for CAD whose underlying pathophysiology may be related to insulin resistance. These risk factors include obesity as defined by increased waist circumference, hypertension, abnormal serum lipids, and an elevated fasting blood glucose[2] (see Table 41-10). These interrelated risk factors of metabolic origin appear to promote the development of CAD. (Chapter 41 discusses metabolic syndrome.)

Psychologic States. The Framingham study provided early evidence that certain behaviors and lifestyles contribute to the development of CAD. Several behavior patterns correlated with CAD. However, the study of these behaviors remains controversial and complex. One type of behavior, referred to as type A, includes perfectionism and a hardworking, driven personality. The type A person often suppresses anger and hostility, has a sense of time urgency, is impatient, and creates stress and tension. This person may be more prone to MIs than a type B person, who is more easygoing, takes upsets in stride, knows personal limitations, takes time to relax, and is not an overachiever. However, findings from studies regarding these relationships are inconsistent.

Studies now are focusing on specific psychologic risk factors thought to increase risk of CAD. These include depression, acute and chronic stress (e.g., poverty, serving as a caregiver), anxiety, hostility and anger, and lack of social support.[10,11] In particular, depression is a risk factor for both the development and worsening of CAD. Depressed patients have elevated levels of circulating catecholamines that may contribute to endothelial injury and inflammation and platelet activation. Higher levels of depression are also associated with an increased number of adverse cardiac events.[10] More research on the treatment of depression and other negative psychologic states (e.g., anger) in patients with or at risk for CAD is needed to improve these patients' emotional and physical health.

Stressful states correlate with the development of CAD.[12] Sympathetic nervous system (SNS) stimulation and its effect on the heart are the physiologic mechanism by which stress predisposes one to the development of CAD. SNS stimulation causes an increased release of catecholamines (i.e., epinephrine, norepinephrine). This stimulation increases HR and intensifies the force of myocardial contraction, resulting in increased myocardial oxygen demand. Also, stress-induced mechanisms can cause elevated lipid and glucose levels and changes in blood coagulation, which can lead to increased atherogenesis.

Homocysteine. High blood levels of homocysteine have been linked to an increased risk for CAD and other cardiovascular diseases.[13] Homocysteine is produced by the breakdown of the essential amino acid methionine, which is found in dietary protein. High homocysteine levels possibly contribute to atherosclerosis by (1) damaging the inner lining of blood vessels, (2) promoting plaque buildup, and (3) altering the clotting mechanism to make clots more likely to occur (see Table 32-6).

Research is ongoing to determine whether a decline in homocysteine can reduce the risk of heart disease. B-complex vitamins (B_6, B_{12}, folic acid) have been shown to lower blood levels of homocysteine. Generally, a screening test for homocysteine is limited to those suspected of having elevated levels, such as older patients with pernicious anemia or people who develop CAD at an early age.

Substance Abuse. The use of illicit drugs, such as cocaine and methamphetamine, can produce coronary spasm resulting in myocardial ischemia and chest pain. Most people who are seen in the ED with drug-induced chest pain are initially indistinguishable from those with CAD. Although MI can occur, these patients more often have sinus tachycardia, high BP, angina, and anxiety.[14]

The U.S. Food and Drug Administration (FDA) prohibits the sale of dietary supplements containing ephedrine alkaloids. These compounds should be avoided because they can cause high BP, MI, and stroke.

NURSING AND COLLABORATIVE MANAGEMENT CORONARY ARTERY DISEASE

HEALTH PROMOTION

The appropriate management of risk factors in CAD may prevent, modify, or slow the progression of the disease. In the

United States during the past 30 years, there has been a gradual and persistent decline in cardiovascular-related deaths. (See eFig. 34-3, available on the website for this chapter.) The decline relates to people's efforts to become generally healthier, as well as advances in drugs and technology to treat CAD. Prevention and early treatment of heart disease must involve a multifaceted approach and needs to be ongoing throughout the life span.

IDENTIFICATION OF HIGH-RISK PEOPLE. Clinical manifestations of CAD are not apparent in the early stages of the disease. Therefore regardless of the health care setting, it is extremely important to identify people at risk for CAD. Risk screening involves obtaining a thorough health history. Question the patient about a family history of heart disease in parents and siblings. Note the presence of any cardiovascular symptoms. Assess environmental factors, such as eating habits, type of diet, and level of exercise, to elicit lifestyle patterns. Include a psychosocial history to determine tobacco use, alcohol ingestion, recent stressful events (e.g., loss of a spouse), and any negative psychologic states (e.g., anxiety, depression, anger). The place and type of employment provide important information on the kind of activity performed, exposure to pollutants or noxious chemicals, and the degree of stress associated with work.

Identify the patient's attitudes and beliefs about health and illness. This information can give some indication of how disease and lifestyle changes may affect the patient and can reveal possible misconceptions about heart disease. Knowledge of the patient's educational background can help to decide the level needed for teaching. If the patient is taking medications, it is important to know the names and dosages and if the patient is compliant with the drug regimen.

MANAGEMENT OF HIGH-RISK PEOPLE. Recommend preventive measures for all persons at risk for CAD. Risk factors such as age, gender, ethnicity, and genetics cannot be modified. However, the person with any of these risk factors can still reduce the risk of CAD by controlling the additive effects of modifiable risk factors. For example, a young man with a family history of heart disease can decrease the risk of CAD by maintaining an ideal body weight, getting adequate physical exercise, reducing intake of saturated fats, and avoiding tobacco use.

Encourage people who have modifiable risk factors to make lifestyle changes to reduce their risk of CAD. You can play a major role in teaching health-promoting behaviors (Table 34-2). For highly motivated persons, knowing how to reduce this risk may be the information they need to get started.

For persons who are less motivated to take charge of their health, the idea of reducing risk factors may be so remote that they are unable to perceive a threat of CAD. Few people desire to make lifestyle changes, especially in the absence of symptoms. First assist these patients in clarifying personal values. Then, by explaining the risk factors and having them identify their vulnerability to various risks, you may help them recognize their susceptibility to CAD. This may help patients set realistic goals and allow them to choose which risk factor(s) to change first. Some persons are reluctant to change until they begin to manifest overt symptoms or actually suffer an MI. Others, having suffered an MI, may find the idea of changing

TABLE 34-2 PATIENT & CAREGIVER TEACHING GUIDE

Reducing Risk Factors for Coronary Artery Disease

Include the following instructions when teaching risk reduction for coronary artery disease.

Risk Factor	Health-Promoting Behaviors
Hypertension	• Monitor home blood pressure (BP) and attend regular checkups. • Take prescribed medications for BP control. • Reduce salt intake (see eFig. 33-1, Your Guide to Lowering Your Blood Pressure with DASH, available on the website for this chapter). • Stop tobacco use. Avoid exposure to environmental tobacco (secondhand) smoke. • Control or reduce weight. • Perform physical activity daily.
Elevated serum lipids	• Reduce total fat intake. • Reduce animal (saturated) fat intake. • Take prescribed medications for lipid reduction. • Adjust total caloric intake to achieve and maintain ideal body weight. • Engage in daily physical activity. • Increase amount of complex carbohydrates, fiber, and vegetable proteins in diet.
Tobacco use*	• Begin a smoking cessation program. • Change daily routines associated with smoking to reduce desire to smoke. • Substitute other activities for smoking. • Ask caregivers to support efforts to stop smoking. • Avoid exposure to environmental tobacco smoke.
Physical inactivity	• Develop and maintain at least 30 min of moderate physical activity daily (minimum 5 days a week). • Increase activities to a fitness level.
Psychologic state	• Increase awareness of behaviors that are harmful to health. • Alter patterns that are conducive to stress (e.g., get up 30 min earlier so breakfast is not eaten on way to work). • Set realistic goals for self. • Reassess priorities in light of health needs. • Learn effective stress management strategies (see Chapter 7). • Seek professional help if feeling depressed, angry, anxious, etc. • Plan time for adequate rest and sleep (see Chapter 8).
Obesity†	• Change eating patterns and habits. • Reduce caloric intake to achieve body mass index of 18.5-24.9 kg/m^2. • Increase physical activity to increase caloric expenditure. • Avoid fad and crash diets, which are not effective over time. • Avoid large, heavy meals. Consider smaller, more frequent meals.
Diabetes‡	• Follow the recommended diet. • Control or reduce weight. • Take prescribed antidiabetic medications. • Monitor blood glucose levels regularly.

*Smoking cessation is discussed in Chapter 11 and Tables 11-4 through 11-6.
†See Chapter 41 for additional health-promoting behaviors.
‡See Chapter 49 for additional health-promoting behaviors.

lifelong habits still unacceptable. Help them identify such choices and respect their final decision.

PHYSICAL ACTIVITY

A physical activity program should be designed to improve physical fitness by following the FITT formula: **F**requency (how often), **I**ntensity (how hard), **T**ype (isotonic), and **T**ime (how long). Everyone should aim for at least 30 minutes of moderate physical activity on most days of the week.[9] In addition, adding weight training to an exercise program two days a week can help treat metabolic syndrome and improve muscle strength. Examples of moderate physical activity include brisk walking, hiking, biking, and swimming. Regular physical activity contributes to weight reduction, reduction in systolic BP, and, in some men more than women, increase in HDL cholesterol. The AHA has developed a program to encourage people, especially women, to increase their daily physical activity (My Heart, My Life at *www.startwalkingnow.org*).

NUTRITIONAL THERAPY

The National Heart, Lung, and Blood Institute recommends therapeutic lifestyle changes for all people to reduce the risk of CAD by lowering LDL cholesterol. These recommendations emphasize a decrease in saturated fat and cholesterol and an increase in complex carbohydrates (e.g., whole grains, fruit, vegetables) and fiber[7] (Tables 34-3 and 34-4). Fat intake should be about 30% of calories, with most coming from mono- and polyunsaturated fats (Fig. 34-3). Red meat, egg yolks, and whole milk products are major sources of saturated fat and cholesterol and should be reduced or eliminated from diets. If the serum triglyceride level is elevated, the guidelines recommend reducing or eliminating alcohol intake and simple sugars.

Omega-3 fatty acids reduce the risks associated with CAD when eaten regularly. For individuals without CAD, the AHA recommends eating fatty fish twice a week because fatty fish such as salmon and tuna contains two types of omega-3 fatty acids: eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA). Patients with CAD are encouraged to take EPA and DHA supplements with their diet. The AHA also recommends eating tofu and other forms of soybean, canola, walnut, and flaxseed because these products contain alpha-linolenic acid, which becomes omega-3 fatty acid in the body. For more information on the AHA's nutritional recommendations, see their website listed in the Resources section at the end of this chapter.

Lifestyle changes, including a low-saturated-fat, high-fiber diet; avoidance of tobacco; and increase in physical activity, can promote the reversal of CAD and reduce coronary events.

LIPID-LOWERING DRUG THERAPY

An estimated 31.9 million American adults have cholesterol levels greater than or equal to 240 mg/dL (6.2 mmol/L).[1] A complete lipid profile is recommended every 5 years beginning at age 20. The person with a serum cholesterol level greater than 200 mg/dL is at risk for CAD and should be treated. Treatment usually begins with dietary caloric restriction (if overweight), decreased dietary fat and cholesterol intake, and increased

TABLE 34-3 NUTRITIONAL THERAPY

Therapeutic Lifestyle Changes Diet

Nutrient	Recommended Daily Intake
Total fat (includes saturated fat calories)	25%-35% of total daily calories
Saturated fat	<7% of total daily calories
Cholesterol	<200 mg
Plant stanols or sterols (e.g., margarines, nuts, seeds, legumes, vegetable oils)*	2 g
Dietary fiber*	10-25 g of soluble fiber
Total calories	Only enough calories to reach or maintain a healthy weight
Physical activity	At least 30 min of a moderate-intensity physical activity (e.g., brisk walking) on most, and preferably all, days of the week

TABLE 34-4 NUTRITIONAL THERAPY

Tips to Implement Diet and Lifestyle Recommendations

General Tips

1. Know your caloric needs to achieve and maintain a healthy weight.
2. Know the calorie content of the foods and beverages you consume.
3. Track your weight, physical activity, and calorie intake.
4. Prepare and eat smaller, more frequent meals.
5. Track your activities and, whenever possible, decrease sedentary activities (e.g., watching television, computer time).
6. Incorporate physical movement into daily activities (e.g., take extra steps when possible).
7. Do not smoke or use tobacco products.
8. If you consume alcohol, do so in moderation (i.e., no more than one drink for women or two drinks for men a day).

Tips Related to Food Choices and Preparation

1. Use the Nutrition Facts panel on food labels and ingredients list when choosing foods to buy.
2. Select frozen and canned vegetables and fruits without high-calorie sauces or added salt and sugars.
3. Replace high-calorie foods with fresh fruits and vegetables.
4. Increase fiber intake by eating beans (legumes), whole-grain products, fruits, and vegetables.
5. Use liquid vegetable oils in place of solid fats.
6. Limit beverages and foods high in added sugars (e.g., sucrose, glucose, fructose, maltose, dextrose, corn syrups, concentrated fruit juice, honey).
7. Choose foods made with whole grains (e.g., whole wheat, oats/oatmeal, rye, barley, corn, popcorn, brown rice, wild rice, buckwheat, cracked wheat, sorghum).
8. Eliminate pastries and high-calorie bakery products (e.g., muffins, doughnuts).
9. Select milk and dairy products that are either fat free or low fat.
10. Reduce salt intake by
    - Comparing the sodium content of similar products (e.g., different brands of tomato sauce) and choosing products with less sodium
    - Choosing versions of processed foods that are reduced in salt, including cereals and baked goods
    - Limiting condiments (e.g., soy sauce, ketchup)
11. Use lean cuts of meat and remove skin from poultry before cooking or eating.
12. Avoid processed meats that are high in saturated fat and sodium (e.g., deli meats).
13. Grill, bake, or broil fish, meat, and poultry.
14. Incorporate vegetable-based meat substitutes into favorite recipes (e.g., soy).
15. Consume whole vegetables and fruits in place of juices.

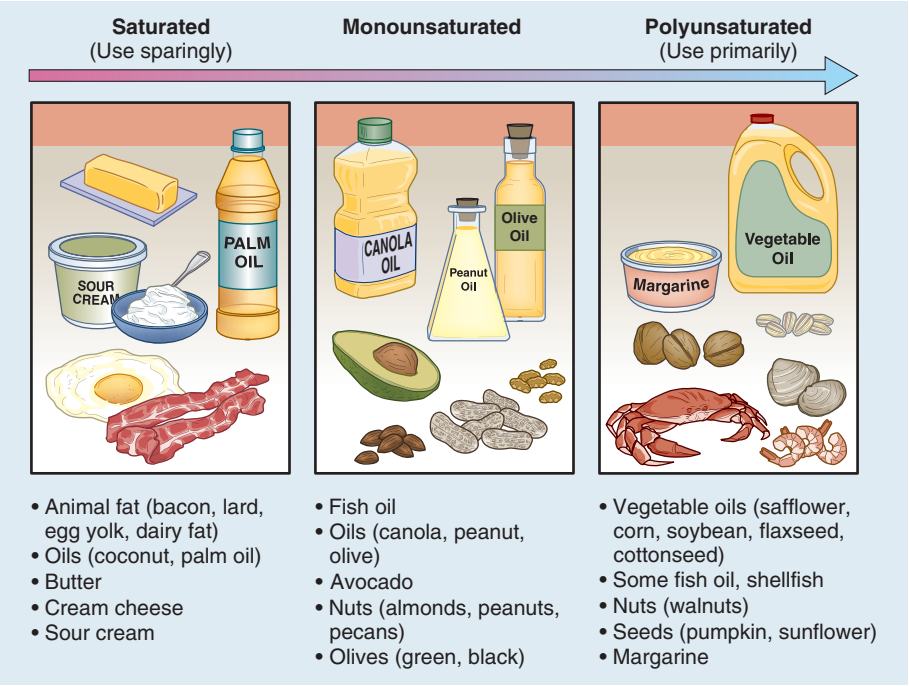

FIG. 34-3 Types of dietary fat.

EVIDENCE-BASED PRACTICE

Translating Research into Practice

Does Dietary Fat Modification Improve Cardiovascular Disease Outcomes?

Clinical Question

For adults (P), what is the effect of dietary fat modification or reduction (I) versus placebo, usual, or control diet (C) on overall mortality and cardiovascular morbidity and mortality (O)?

Best Available Evidence

Systematic review of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- 48 RCTs with 60 comparisons ($n = 81,327$) of adults with or without existing cardiovascular disease. Intervention was reduced or modified dietary fat intake compared with placebo, usual, or control diet.
- Low-fat diet reduced energy intake to <30% from fat, and partially replaced fats with carbohydrates (simple or complex), protein, or fruit and vegetables.
- Modified fat diet had 30% or more energy intake from total fats with more monounsaturated or polyunsaturated fats than usual diet.

Conclusion

- Reducing saturated fat by reducing and/or modifying dietary fat reduced the risk of cardiovascular events.
- Risk for cardiovascular disease decreased in men (not women) by dietary fat modification.

Implications for Nursing Practice

- Counsel patients on modifying dietary fat intake by substituting monounsaturated or polyunsaturated fats for saturated fats.
- Assist the patient in collaboration with the dietitian to maintain long-term dietary fat changes.

COMPLEMENTARY & ALTERNATIVE THERAPIES

*Lipid-Lowering Agents**

Agent	Evidence for Use
Garlic	Inconsistent scientific evidence for reductions in total cholesterol and low-density lipoproteins (LDLs) over short periods.
Niacin	Strong scientific evidence for increased high-density lipoproteins. Less dramatic reduction of LDLs.
Omega-3 fatty acids	Strong scientific evidence for reduction of triglyceride levels.
Psyllium	Strong scientific evidence for modest reduction in total cholesterol and LDLs.
Plant sterols	Strong scientific evidence for reduction of total cholesterol.
Red yeast rice	Strong scientific evidence for reduction of total cholesterol, LDLs, and triglycerides.
Soy	Strong scientific evidence for moderate reduction in total cholesterol and LDLs.

Based on a systematic review of scientific literature. Available at *www.naturalstandard.com*.

*Cardiovascular disease is a serious health problem. Herbal or other natural therapy should not be initiated without consultation with a health care provider. This is especially important when conventional drug therapy for cardiovascular disease is also being used.

physical activity. The guidelines for treatment of high cholesterol focus on LDL levels. Serum lipid levels are reassessed after 6 weeks of diet therapy. If they remain elevated, additional dietary options (see the Complementary & Alternative Therapies box above) and drug therapy (Table 34-5) may be considered.

DRUGS THAT RESTRICT LIPOPROTEIN PRODUCTION. The statin drugs are the most widely used lipid-lowering drugs. These drugs inhibit the synthesis of cholesterol in the liver. An unexplained result of the inhibition of cholesterol synthesis is an increase in hepatic LDL receptors. Consequently, the liver is able to remove more LDLs from the blood. In addition, statins

TABLE 34-5 DRUG THERAPY

Hyperlipidemia

Drug	Mechanism of Action	Side Effects	Nursing Considerations
Restrict Lipoprotein Production			
HMG-CoA Reductase Inhibitors (Statins)			
atorvastatin (Lipitor) fluvastatin (Lescol) lovastatin (Mevacor) pitavastatin (Livalo) pravastatin (Pravachol) simvastatin (Zocor) rosuvastatin (Crestor)	Block synthesis of cholesterol and increase LDL receptors in liver ↓ LDL ↓ Triglycerides ↑ HDL	Rash, GI disturbances, elevated liver enzymes, myopathy, rhabdomyolysis	Well tolerated with few side effects. Monitor liver enzymes and creatine kinase (if muscle weakness or pain occurs).
Niacin			
niacin (Nicobid, Niaspan) nicotinic acid (Slo-Niacin, Novo-Niacin)	Inhibits synthesis and secretion of VLDL and LDL ↓ LDL ↓ Triglycerides ↑ HDL	Flushing and pruritus in upper torso and face, GI disturbances (e.g., nausea and vomiting, dyspepsia, diarrhea), orthostatic hypotension, elevated homocysteine levels	Most side effects subside with time. Decreased liver function may occur with high doses. Taking aspirin or NSAID 30 min before drug may prevent flushing. Take drug with food. Treat elevated homocysteine levels with folic acid.
Fibric Acid Derivatives			
fenofibrate (TriCor) gemfibrozil (Lopid)	Decrease hepatic synthesis and secretion of VLDL. Reduce triglycerides by ↓ VLDL ↓ LDL ↓ Triglycerides ↑ HDL	Rashes, mild GI disturbances (e.g., nausea, diarrhea), elevated liver enzymes	May ↑ effects of warfarin (Coumadin) and some antihyperglycemic drugs. When used in combination with statins, may increase adverse effects of statins, especially myopathy.
Omega-3 Fatty Acid			
icosapent ethyl (Vascepa)	Inhibits synthesis and/or secretion of triglycerides	Arthralgia	Used for patients with severe hypertriglyceridemia (levels ≥500 mg/dL).
Increase Lipoprotein Removal			
Bile-Acid Sequestrants			
cholestyramine (Questran) colesevelam (WelChol) colestipol (Colestid)	Bind with bile acids in intestine, forming insoluble complex and excreted in feces Binding results in removal of LDL and cholesterol ↓ LDL	Unpleasant quality to taste, GI disturbances (e.g., indigestion, constipation, bloating)	Effective and safe for long-term use. Side effects diminish with time. Interfere with absorption of many drugs (e.g., digoxin, thiazide diuretics, warfarin, some antibiotics [e.g., penicillins]).
Decrease Cholesterol Absorption			
Cholesterol Absorption Inhibitor			
ezetimibe (Zetia)	Inhibits the intestinal absorption of cholesterol ↓ LDL ↑ HDL	Infrequent, but may include headache and mild GI distress	When used with a statin, LDL is further reduced. Should not be used by patients with liver impairment.

produce a small increase in HDLs and lower CRP levels.[15] Serious adverse effects of these drugs are rare and include liver damage and myopathy that can progress to rhabdomyolysis (breakdown of skeletal muscle). Liver enzymes (e.g., aspartate aminotransferase, alanine aminotransferase) are initially monitored and rechecked with any increase in dosage. Creatine kinase isoenzymes (e.g., CK-MM) are assessed if symptoms of myopathy (e.g., muscle aches, weakness) occur.[15]

DRUG ALERT

Simvastatin (Zocor)

- Increased risk for rhabdomyolysis when also used with gemfibrozil (Lopid) or niacin (Niaspan)
- Signs of rhabdomyolysis: ↑ creatine kinase levels, muscle tenderness

Niacin, a water-soluble B vitamin, is highly effective in lowering LDL and triglyceride levels by interfering with their synthesis. Niacin also increases HDL levels better than many other lipid-lowering drugs. Unfortunately, side effects of this drug are common and may include severe flushing, pruritus, gastrointestinal (GI) symptoms, and orthostatic hypotension.

DRUG ALERT

Niacin (Niaspan)

- Instruct patient that flushing (especially of face and neck) may occur within 20 minutes after taking drug and may last for 30 to 60 minutes.
- Patient can premedicate with aspirin or nonsteroidal antiinflammatory drug (NSAID) 30 minutes before administration to reduce flushing.
- Use of extended-release niacin may decrease side effects.

The *fibric acid derivatives* (see Table 34-5) work by aiding the removal of VLDLs and increasing the production of apolipoproteins A-I and A-II. They are the most effective drugs for lowering triglycerides and increasing HDL levels. They have no effect on LDLs. Although most patients tolerate the drugs well, complaints may include GI irritability. These drugs should be used with caution when combined with statin medications.

DRUG ALERT

Gemfibrozil (Lopid)

- May increase the risk of bleeding in patients taking warfarin (Coumadin)
- May increase the effects of antihyperglycemic drugs (e.g., repaglinide [Prandin])

DRUGS THAT INCREASE LIPOPROTEIN REMOVAL. The major route of elimination of cholesterol is by conversion to bile acids in the liver. Bile-acid sequestrants increase conversion of cholesterol to bile acids and decrease hepatic cholesterol. The primary effect is a decrease in total cholesterol and LDLs.

Administration of these drugs can be associated with complaints related to taste and a variety of upper and lower GI symptoms. These include belching, heartburn, nausea, abdominal pain, and constipation. The bile-acid sequestrants interfere with absorption of many other drugs (e.g., warfarin, thiazides, thyroid hormones, β-adrenergic blockers). Separating the time of administration of these drugs from that of other drugs decreases this adverse effect.[15]

DRUGS THAT DECREASE CHOLESTEROL ABSORPTION. Ezetimibe (Zetia) selectively inhibits the absorption of dietary and biliary cholesterol across the intestinal wall. It serves as an adjunct to dietary changes, especially in patients with primary hypercholesterolemia. When it is combined with a statin (e.g., ezetimibe and simvastatin [Vytorin]), even greater reductions in LDLs are found.

Drug therapy for hyperlipidemia often continues for a lifetime. New combination drug therapy (e.g., atorvastatin/ezetimibe [Liptruzet]) is available and may be considered. Concurrent diet modification is essential to minimize the need for drug therapy. The patient must fully understand the rationale and goals of treatment, as well as the safety and side effects of lipid-lowering drug therapy.

ANTIPLATELET THERAPY

Unless contraindicated (e.g., history of GI bleeding), low-dose aspirin (81 mg) is recommended for most people at risk for CAD (see eFig. 34-5, What you need to know—antiplatelet therapy, available on the website for this chapter). Current recommendations include low-dose aspirin for men over 45 years and high-risk women (i.e., those with a calculated 10-year CAD risk of more than 20%) unless contraindicated. For high-risk women who are intolerant of aspirin, clopidogrel (Plavix) can be substituted. In healthy women 65 years or older, aspirin therapy should be considered if BP is controlled and the benefit for MI prevention outweighs the risk of GI bleed or hemorrhagic stroke.[16]

GERONTOLOGIC CONSIDERATIONS

CORONARY ARTERY DISEASE

The incidence of cardiac disease is greatly increased in older adults and is the leading cause of death in older persons.[1] In the older adult, CAD is often a result of the complex interaction of nonmodifiable risk factors (e.g., age) and lifelong modifiable risk behaviors (e.g., inactivity, tobacco use). Strategies to reduce CAD risk and to treat CAD are effective in this age-group.[16]

Aggressive treatment of hypertension and hyperlipidemia stabilizes plaques in the coronary arteries of older adults, and cessation of tobacco use helps decrease the risk for CAD at any age.[16] Similarly, encourage the older patient to consider a planned program of physical activity. Activity performance, endurance, and ability to tolerate stress are improved in the older adult with physical training. Positive psychologic benefits from physical activity can include increased self-esteem and emotional well-being and improved body image. For the older adult who is obese, making modest dietary changes and slowly increasing physical activity (e.g., walking) results in more positive benefits than aiming for a significant weight loss.

When planning a physical activity program for the older adult, recommend the following: (1) longer warm-up periods, (2) longer periods of low-level activity, or (3) longer rest periods between sessions. Heat intolerance in the older adult results from a decreased ability to sweat efficiently. Teach the patient to avoid physical activity in extremes of temperature and to maintain a moderate pace. The older adult should exercise a minimum of 30 minutes on most days of the week as able.[9]

Encouraging the older patient to adopt a healthy lifestyle may increase the quality of life and reduce the risk of CAD and fatal cardiac events. Older adults face many of the same challenges as younger persons when it comes to making lifestyle changes. Older adults are more likely to consider change at two points in time: (1) when hospitalized and (2) when symptoms (e.g., chest pain) are the result of CAD and not normal aging (see Table 32-1). First, assess the older adult for readiness to change, and then help the patient select the lifestyle changes most likely to produce the greatest reduction in risk for CAD.

CHRONIC STABLE ANGINA

CAD is a progressive disease, and patients may be asymptomatic for many years or may develop chronic stable chest pain. When the demand for myocardial oxygen exceeds the ability of the coronary arteries to supply the heart with oxygen, *myocardial ischemia* occurs. **Angina,** or chest pain, is the clinical manifestation of reversible myocardial ischemia. Either an increased demand for oxygen or a decreased supply of oxygen can lead to myocardial ischemia (Table 34-6). The primary reason for insufficient blood flow is narrowing of coronary arteries by atherosclerosis. For ischemia secondary to atherosclerosis to occur, the artery is usually blocked (stenosed) 75% or more.

On the cellular level, the myocardium becomes hypoxic within the first 10 seconds of coronary occlusion. Myocardial cells are deprived of oxygen and glucose needed for aerobic

TABLE 34-6 FACTORS INFLUENCING MYOCARDIAL OXYGEN NEEDS*

Decreased Oxygen Supply	Increased Oxygen Demand or Consumption
Cardiac	
• Coronary artery spasm	• Aortic stenosis
• Coronary artery thrombosis	• Cardiomyopathy
• Dysrhythmias	• Dysrhythmias
• Heart failure	• Tachycardia
• Valve disorders	
Noncardiac	
• Anemia	• Anxiety
• Asthma	• Hypertension
• Chronic obstructive pulmonary disease	• Hyperthermia
• Hypovolemia	• Hyperthyroidism
• Hypoxemia	• Physical exertion
• Pneumonia	• Substance abuse (e.g., cocaine, ephedrine)

*Lists are not all-inclusive.

metabolism and contractility. Anaerobic metabolism begins, and lactic acid accumulates. Lactic acid irritates myocardial nerve fibers and transmits a pain message to the cardiac nerves and upper thoracic posterior nerve roots. This accounts for referred cardiac pain to the shoulders, neck, lower jaw, and arms. In ischemic conditions, cardiac cells are viable for approximately 20 minutes. With restoration of blood flow, aerobic metabolism resumes, contractility is restored, and cellular repair begins.

Chronic stable angina refers to chest pain that occurs intermittently over a long period with the same pattern of onset, duration, and intensity of symptoms. When questioned, some patients may deny feeling pain but describe a pressure or ache in the chest (Table 34-7). It is an unpleasant feeling, often described as a squeezing, heavy, choking, or suffocating sensation. Angina is rarely sharp or stabbing, and it usually does not change with position or breathing. Many people with angina complain of indigestion or a burning sensation in the epigastric region. Although most angina pain appears substernally, the sensation may occur in the neck or radiate to various locations, including the lower jaw, the shoulders, and the arms (Fig. 34-4). Often people complain of pain between the shoulder blades and dismiss it as not being heart related.

The pain usually lasts for only a few minutes (5 to 15 minutes) and commonly subsides when the precipitating factor is resolved (Table 34-8). Pain at rest is unusual. A 12-lead electrocardiogram (ECG) often shows ST segment depression and/or T wave inversion indicating ischemia (see Chapter 36). The ECG returns to baseline when the pain is relieved.

Chronic stable angina is controlled with medications on an outpatient basis. Because chronic stable angina is often predictable, medications are timed to provide peak effects during the

TABLE 34-7 PQRST ASSESSMENT OF ANGINA

Use the following memory aid to obtain information from the patient who has chest pain.

	Factor	Questions to Ask Patient
P	Precipitating events	What events or activities precipitated the pain (e.g., argument, exercise, resting)?
Q	Quality of pain	What does the pain feel like (e.g., pressure, dull, aching, tight, squeezing, heaviness)?
R	Radiation of pain	Where is the pain located? Does the pain radiate to other areas (e.g., back, neck, arms, jaw, shoulder, elbow)?
S	Severity of pain	On a scale of 0 to 10 with 0 indicating no pain and 10 being the most severe pain you could imagine, what number would you give the pain?
T	Timing	When did the pain begin? Has the pain changed since this time? Have you had pain like this before?

TABLE 34-8 PRECIPITATING FACTORS OF ANGINA

Physical Exertion
- Increases HR, reducing the time the heart spends in diastole (the time of greatest coronary blood flow), resulting in an increase in myocardial oxygen demand.
- Isometric exercise of the arms (e.g., raking, lifting heavy objects, snow shoveling) can cause exertional angina.

Temperature Extremes
- Increase the workload of the heart.
- Blood vessels constrict in response to a cold stimulus.
- Blood vessels dilate and blood pools in the skin in response to a hot stimulus.

Strong Emotions
- Stimulate the sympathetic nervous system, activating the stress response.
- Increase the workload of the heart.

Consumption of Heavy Meal
- Can increase the workload of the heart.
- During the digestive process, blood is diverted to the GI system, reducing blood flow in the coronary arteries.

Tobacco Use, Environmental Tobacco Smoke
- Nicotine stimulates catecholamine release, causing vasoconstriction and an increased HR.
- Diminishes available oxygen by increasing the level of carbon monoxide.

Sexual Activity
- Increases the cardiac workload and sympathetic stimulation.
- In a person with CAD, the extra cardiac workload may precipitate angina.

Stimulants (e.g., cocaine, amphetamines)
- Increase HR and subsequent myocardial oxygen demand.

Circadian Rhythm Patterns
- Related to the occurrence of chronic stable angina, Prinzmetal's angina, MI, and sudden cardiac death.
- Manifestations of CAD tend to occur in the early morning after awakening.

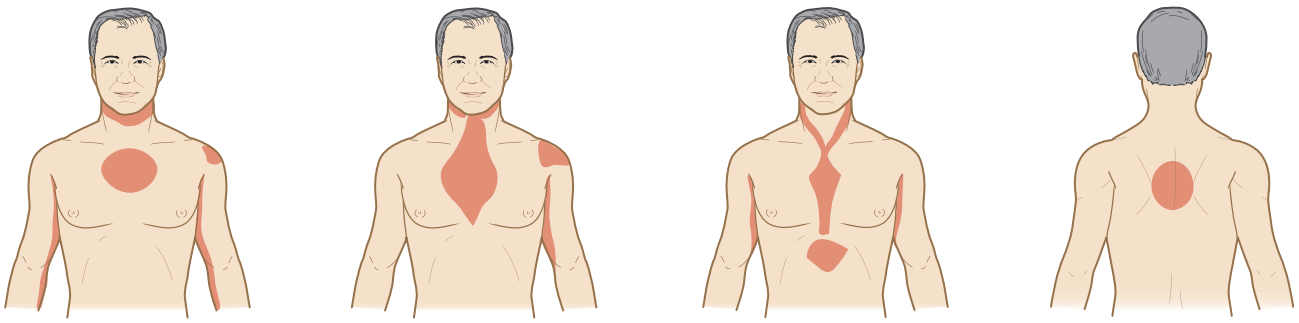

FIG. 34-4 Common locations and patterns of pain during angina or myocardial infarction.

TABLE 34-9 COMPARISON OF MAJOR TYPES OF ANGINA

Type	Etiology	Characteristics
Chronic stable angina	Myocardial ischemia, usually secondary to CAD	• Episodic pain lasting 5-15 min • Provoked by exertion • Relieved by rest or nitroglycerin
Prinzmetal's angina	Coronary vasospasm	• Occurs primarily at rest • Triggered by smoking and increased levels of some substances (e.g., histamine, epinephrine) • May occur in presence or absence of CAD
Microvascular angina	Myocardial ischemia secondary to microvascular disease affecting the small, distal branches of the coronary arteries	• More common in women • Triggered by activities of daily living (e.g., shopping, work) vs. physical exercise (exertion) • Treatment may include nitroglycerin
Unstable angina	Rupture of thickened plaque, exposing thrombogenic surface	• New-onset angina • Chronic stable angina that increases in frequency, duration, or severity • Occurs at rest or with minimal exertion • Pain refractory to nitroglycerin

time of day when angina is likely to occur. For example, if angina occurs when rising, the patient can take medication as soon as awakening and wait 30 minutes to 1 hour before engaging in activity. (See Table 34-9 for a comparison of the major types of angina.)

Silent Ischemia

Silent ischemia refers to ischemia that occurs in the absence of any subjective symptoms. Patients with diabetes have an increased prevalence of silent ischemia. This is most likely due to diabetic neuropathy affecting the nerves that innervate the cardiovascular system. When patients are monitored (e.g., Holter monitor) and silent ischemia occurs, ECG changes are revealed. Ischemia with pain or without pain has the same prognosis.

Nocturnal Angina and Angina Decubitus

Nocturnal angina occurs only at night but not necessarily when the person is in the recumbent position or during sleep. *Angina decubitus* is chest pain that occurs only while the person is lying down and is usually relieved by standing or sitting.

Prinzmetal's Angina

Prinzmetal's angina *(variant angina)* often occurs at rest, usually in response to spasm of a major coronary artery. It is a rare form of angina frequently seen in patients with a history of migraine headaches and Raynaud's phenomenon. The spasm may occur in the absence or presence of CAD. Prinzmetal's angina is not usually precipitated by increased physical demand. Strong contraction (spasm) of smooth muscle in the coronary artery results from increased intracellular calcium.

Factors causing coronary artery spasm include increased myocardial oxygen demand and increased levels of certain substances (e.g., tobacco smoke, alcohol, amphetamines). When spasm occurs, the patient experiences angina and transient ST segment elevation (see Chapter 36). The pain may occur during rapid-eye-movement (REM) sleep when myocardial oxygen consumption increases. The pain may be relieved by moderate exercise, or it may disappear spontaneously. Cyclic, short bursts of pain at a usual time each day may also occur with this type of angina. Calcium channel blockers and/or nitrates are used to control the angina.

TABLE 34-10 TREATMENT OF CHRONIC STABLE ANGINA

*Strategies for the patient with chronic stable angina should address all the treatment elements and related patient teaching in the following mnemonic:**

Element	Treatment
A	Antiplatelet/anticoagulant therapy Antianginal therapy ACE inhibitor/angiotensin receptor blocker
B	β-adrenergic blocker Blood pressure control
C	Cigarette smoking cessation Cholesterol (lipid) management Calcium channel blockers Cardiac rehabilitation
D	Diet (weight management) Diabetes management Depression screening
E	Education Exercise
F	Flu vaccination

*Modified from Smith SC, Benjamin EJ, Bonow RO, et al: AHA/ACCF secondary prevention and risk reduction therapy for patients with coronary and other atherosclerotic vascular disease: 2011 update, *J Am Coll Cardiol* 58:2432, 2011.

Microvascular Angina

In *microvascular angina,* chest pain occurs in the absence of significant coronary atherosclerosis or coronary spasm, especially in women.[2] In these patients, chest pain is related to myocardial ischemia associated with abnormalities of the coronary microcirculation. This is known as coronary microvascular disease (MVD).

Coronary MVD affects the small branches of the distal coronary arteries, whereas CAD affects larger coronary arteries. In coronary MVD, plaque can be diffuse, be evenly distributed, or develop as blockages in the tiny coronary arteries. Prevention and treatment of coronary MVD follow the same recommendations as for CAD.[2]

COLLABORATIVE CARE CHRONIC STABLE ANGINA

The treatment of chronic stable angina aims to decrease oxygen demand and/or increase oxygen supply. The reduction of risk factors is a priority and should include those strategies discussed for patients with CAD (see pp. 735-740). In addition to antiplatelet and lipid-lowering drug therapy, the most common therapeutic interventions for the management of chronic stable angina are the use of nitrates, angiotensin-converting enzyme (ACE) inhibitors, β-adrenergic blockers, and calcium channel blockers to optimize myocardial perfusion[17] (Table 34-10 and Fig. 34-5).

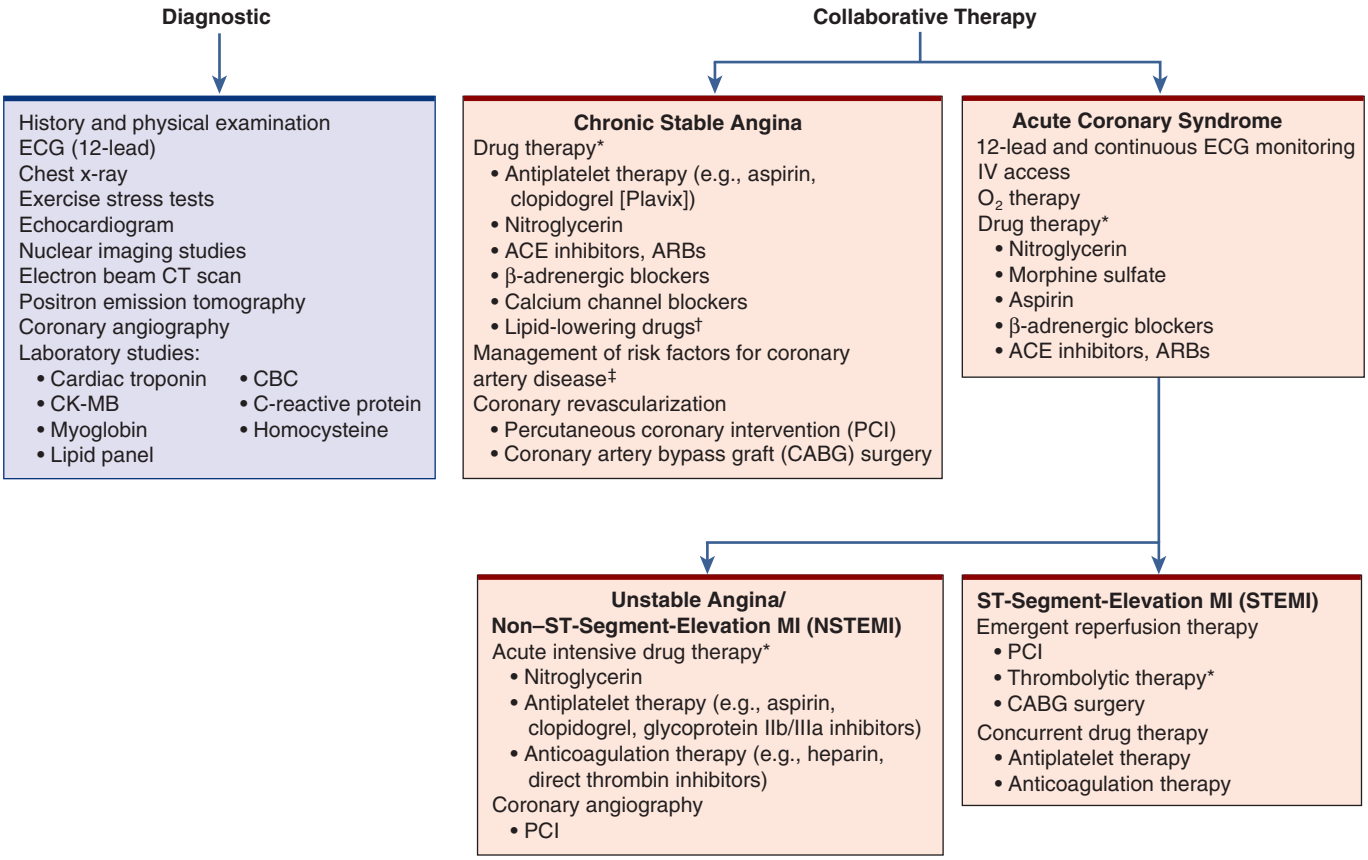

FIG. 34-5 Collaborative care: chronic stable angina and acute coronary syndrome. *ACE,* Angiotensin-converting enzyme; *ARBs,* angiotensin II receptor blockers; *CK,* creatine kinase.

†, see Table 34-5.
‡, see Tables 34-2, 34-3, and 34-4.

Drug Therapy

Drug therapy for chronic stable angina aims to prevent MI and death, and reduce symptoms. Aspirin (previously discussed) is given in the absence of contraindications (Table 34-11).

Short-Acting Nitrates. Short-acting nitrates are first-line therapy for the treatment of angina. Nitrates produce their principal effects by the following mechanisms:

Dilating peripheral blood vessels: This results in decreased SVR, venous pooling, and decreased venous blood return to the heart (preload). Therefore myocardial oxygen demand is decreased because of the reduced cardiac workload.

Dilating coronary arteries and collateral vessels: This may increase blood flow to the ischemic areas of the heart. However, when the coronary arteries are severely atherosclerotic, coronary dilation is difficult to achieve.

Sublingual Nitroglycerin. Nitroglycerin (NTG) given sublingually (Nitrostat) or by translingual spray (Nitrolingual) usually relieves pain in about 3 minutes and has a duration of approximately 30 to 40 minutes. The recommended dose for the patient who has been prescribed NTG is one tablet taken sublingually (SL) or one metered spray for symptoms of angina. If symptoms are unchanged or worse after 5 minutes, tell the patient or caregiver to repeat NTG every 5 minutes for a maximum of three doses and contact EMS if symptoms have not resolved completely.[17]

Instruct the patient in the proper use of NTG. It should be easily accessible to the patient at all times. The patient should store the tablets away from light and heat sources, including body heat, to protect them from degradation. Tablets are packaged in light-resistant bottles with metal caps. Once opened, the tablets lose potency and should be replaced every 6 months.

Tell the patient to place a NTG tablet under the tongue and allow it to dissolve. If using the spray, the patient should direct it on the tongue, not inhale it. NTG should cause a tingling sensation when administered; otherwise it may be outdated. Warn the patient that a headache, dizziness, or flushing may occur. Caution the patient to change positions slowly after NTG use because orthostatic hypotension may occur.

Patients can use NTG prophylactically before starting an activity that is known to cause an anginal attack. In these cases the patient can take a tablet or spray 5 to 10 minutes before beginning the activity. Instruct the patient to report any changes in the usual pattern of pain, especially increasing frequency or nocturnal angina, to the health care provider.

Long-Acting Nitrates. Nitrates, such as isosorbide dinitrate (Isordil) and isosorbide mononitrate (Imdur), are longer acting than SL or translingual NTG. They are used to reduce the incidence of anginal attacks. The main side effect of all nitrates is headache from the dilation of cerebral blood vessels. Advise patients to take acetaminophen (Tylenol) with their nitrate to relieve the headache. Over time, the headaches may decrease, but the antianginal effect is still present.

TABLE 34-11 DRUG THERAPY

Chronic Stable Angina and Acute Coronary Syndrome

Drug	Mechanism of Action and Comments
Antiplatelet Agents	
aspirin	• Inhibits cyclooxygenase, which in turn produces thromboxane A_2, a potent platelet activator • Should be administered as soon as ACS is suspected
clopidogrel (Plavix)	• Inhibits platelet aggregation • Alternative for patient who cannot use aspirin or used in combination with aspirin
prasugrel (Effient)	• Inhibits platelet aggregation • Used as an alternative to clopidogrel or used in combination with aspirin
ticagrelor (Brilinta)	• Inhibits platelet aggregation • Alternative for patient who cannot use aspirin • If used in combination with aspirin, effectiveness may be decreased by aspirin dosages >100 mg/day (according to a boxed warning)
Glycoprotein IIb/IIIa Inhibitors	
abciximab (ReoPro) eptifibatide (Integrilin) tirofiban (Aggrastat)	• Prevent the binding of fibrinogen to platelets, thereby blocking platelet aggregation • Standard antiplatelet therapy in combination with aspirin for patients at high risk for unstable angina
Anticoagulant Agents	
Unfractionated Heparin*	
heparin (Hep-Lock)	• Prevents conversion of fibrinogen to fibrin and prothrombin to thrombin
Low-Molecular-Weight Heparin*	
dalteparin (Fragmin) enoxaparin (Lovenox)	• Bind to antithrombin III, enhancing its effect • Heparin–antithrombin III complex inactivates activated factor X and thrombin • Prevent conversion of fibrinogen to fibrin
Vitamin K Antagonist*	
warfarin (Coumadin)	• Interferes with hepatic synthesis of vitamin K–dependent clotting factors • Alternative for patient who cannot use aspirin or clopidogrel
Direct Thrombin Inhibitors	
bivalirudin (Angiomax) argatroban (Acova)	• Direct inhibition of the clotting factor thrombin

Drug	Mechanism of Action and Comments
Nitrates	
Sublingual nitroglycerin (Nitrostat) Translingual spray nitroglycerin (Nitrolingual) nitroglycerin ointment (Nitro-Bid) Transdermal nitroglycerin (Transderm-Nitro) isosorbide dinitrate (Isordil) IV nitroglycerin (Tridil)	• Promote peripheral vasodilation, decreasing preload and afterload • Promote coronary artery vasodilation
Angiotensin-Converting Enzyme (ACE) Inhibitors†	
captopril (Capoten) enalapril (Vasotec) lisinopril (Zestril)	• Prevent conversion of angiotensin I to angiotensin II, resulting in vasodilation • May prevent or limit ventricular remodeling • Decrease endothelial dysfunction • Useful with heart failure, tachycardia, MI, hypertension, diabetes, and chronic kidney disease
Angiotensin II Receptor Blockers†	
losartan (Cozaar) valsartan (Diovan)	• Inhibit binding of angiotensin II to angiotensin I receptors, resulting in vasodilation • Used for patients intolerant of ACE inhibitors
β-Adrenergic Blockers†	
atenolol (Tenormin) carvedilol (Coreg) metoprolol (Lopressor) nadolol (Corgard)	• Inhibit sympathetic nervous stimulation of the heart • Reduce heart rate, contractility, and blood pressure • Decrease afterload
Calcium Channel Blockers†	
amlodipine (Norvasc) diltiazem (Cardizem) felodipine (Plendil) nicardipine (Cardene) verapamil (Calan)	• Prevent calcium entry into vascular smooth muscle cells and myocytes (cardiac cells) • May prevent or control coronary vasospasm • Promote coronary and peripheral vasodilation • Reduce heart rate, contractility, and blood pressure
Opioid Analgesics	
morphine (morphine sulfate)	• Functions as an analgesic and sedative • Acts as a vasodilator to reduce preload and myocardial O_2 consumption
Thrombolytic Agents	
reteplase (Retavase) alteplase (Activase) tenecteplase (TNKase)	• Breaks up fibrin meshwork in clots • Used only in ST-segment-elevation MI

*See Table 38-10.
†See Table 33-7.

Orthostatic hypotension is a complication of all nitrates. Monitor BP after the initial dose, since the venous dilation that occurs may cause a drop in BP, especially in volume-depleted patients. To limit this, patients are often scheduled an 8-hour nitrate-free period every day, usually during the night, unless the patient experiences nocturnal angina.[15] Finally, tolerance to NTG-induced vasodilation can develop.

Nitroglycerin Ointment. Nitropaste is a 2% NTG topical ointment dosed by the inch. It is placed on the upper body or arm, over a flat muscular area that is free of hair and scars. Once absorbed, it produces anginal prophylaxis for 3 to 6 hours. It is especially useful for nocturnal and unstable angina.

Transdermal Controlled-Release Nitrates. Currently two systems are available for transdermal NTG drug administration: reservoir and matrix. The reservoir system delivers the drug using a rate-controlled permeable membrane. The matrix system provides for a slow delivery of the drug through a polymer matrix. Both reservoir and matrix delivery systems offer the advantages of steady plasma levels within the therapeutic range during 24 hours, thus making only one application a day necessary. The reservoir system has the disadvantage of dose dumping if the reservoir seal is punctured or broken. An advantage of the matrix system is that there can be no dose dumping. Both systems achieve steady plasma levels by 2 hours.

DRUG ALERT

Nitroglycerin

- SL tablet must be administered under the tongue. Translingual NTG should be sprayed on the tongue.
- Instruct patient not to combine with drugs used for erectile dysfunction (e.g., sildenafil [Viagra]).
- Monitor for orthostatic hypotension because it may occur after administration.
- Use gloves to apply and remove NTG ointment or transdermal patch to avoid contact with medication.
- Never discharge cardioverter-defibrillator over NTG ointment or transdermal patch.

Angiotensin-Converting Enzyme Inhibitors. Patients with chronic stable angina who are considered high risk for a cardiac event (e.g., ejection fraction [EF] 40% or less, history of diabetes) should take an ACE inhibitor (e.g., captopril [Capoten]) indefinitely.[17] ACE inhibitors are also used for lower risk patients (e.g., patients with mildly reduced EF).

These drugs result in vasodilation and reduced blood volume. Most important, they can prevent or reverse ventricular remodeling (see p. 748). For patients who are intolerant of ACE inhibitors, angiotensin II receptor blockers (e.g., losartan [Cozaar]) are used. (ACE inhibitors and angiotensin II receptor blockers are discussed later in the chapter and in Chapter 33 and Table 33-7.)

β-Adrenergic Blockers. Patients who have left ventricular dysfunction, have elevated BP, or have had an MI should start and continue β-adrenergic blockers indefinitely.[17] These drugs decrease myocardial contractility, HR, SVR, and BP, all of which reduce the myocardial oxygen demand.

β-Adrenergic blockers have many side effects and can be poorly tolerated. Side effects may include bradycardia, hypotension, wheezing, and GI complaints. Many patients also complain of weight gain, depression, and sexual dysfunction. Patients with asthma should avoid β-adrenergic blockers. They are used cautiously in patients with diabetes, since they mask signs of hypoglycemia. β-Adrenergic blockers should not be discontinued abruptly without medical supervision. This may precipitate an increase in the frequency and intensity of angina attacks.

Calcium Channel Blockers. If β-adrenergic blockers are contraindicated, are poorly tolerated, or do not control anginal symptoms, calcium channel blockers are used.[17] These drugs are also used to manage Prinzmetal's angina. The three primary effects of calcium channel blockers are (1) systemic vasodilation with decreased SVR, (2) decreased myocardial contractility, and (3) coronary vasodilation. Most of these agents have sustained-release versions for longer action with the hope of increased patient adherence and stable blood levels of the drug.

Cardiac muscle and vascular smooth muscle cells are more dependent on extracellular calcium than skeletal muscles. Therefore these cells are more sensitive to calcium channel blocking agents. Calcium channel blockers cause smooth muscle relaxation and relative vasodilation of coronary and systemic arteries, thus increasing blood flow.

Calcium channel blockers potentiate the action of digoxin by increasing serum digoxin levels. Therefore serum digoxin levels should be closely monitored after starting calcium channel blockers. Teach the patient the signs and symptoms of digoxin toxicity (see Chapter 35).

Sodium Current Inhibitor. Ranolazine (Ranexa), a sodium current inhibitor, is used to treat chronic angina in those patients who have not achieved adequate response with other antianginals.[17] Because ranolazine prolongs the QT interval, patients with a long QT interval or who are taking QT-prolonging drugs (e.g., fluoxetine [Prozac]) should not use it. Common side effects of ranolazine include dizziness, nausea, constipation, and generalized weakness.[15]

Diagnostic Studies

When a patient has a history of CAD or CAD is suspected, a variety of studies are completed (see Fig. 34-5). After a detailed health history and physical examination, a chest x-ray is done to look for cardiac enlargement, aortic calcifications, and pulmonary congestion. A 12-lead ECG is obtained and compared with a previous tracing when possible. Certain laboratory tests (e.g., lipid profile) and diagnostic studies (e.g., echocardiogram) are done to confirm CAD and identify specific risk factors for CAD.

Measurement of coronary calcification can be useful for predicting adverse cardiac events. The degree of coronary artery calcification correlates with the severity of CAD. The calcium-score screening heart scan locates calcium deposits in atherosclerotic plaque in the coronary arteries (see Fig. 32-11). However, additional testing (e.g., stress testing) is needed to know the impact of the lesion on coronary blood flow.

For patients with known CAD and chronic stable angina, common diagnostic studies include 12-lead ECG, echocardiogram, exercise stress testing, and pharmacologic nuclear imaging. (See Chapter 32 and Table 32-6 for a discussion of these studies, including nursing considerations.)

Cardiac Catheterization. For patients with increasing symptoms or with a significant amount of myocardium that is ischemic under stress, a cardiac catheterization is ordered. Cardiac catheterization and coronary angiography provide images of the coronary circulation and identify the location and severity of any blockage.

If a coronary blockage is amenable to an intervention, **coronary revascularization** with an elective **percutaneous coronary intervention (PCI)** is done.[17] During this procedure,

EVIDENCE-BASED PRACTICE

Translating Research into Practice

Does Timing of Ambulation Affect Patient Safety After Percutaneous Coronary Intervention?

Clinical Question

Among patients following percutaneous coronary interventions (P), what is the effect of ambulation (I) early versus late (T) on bleeding and hematoma (O)?

Best Available Evidence

Meta-analysis of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- Five RCTs (n = 1854) of patients comparing safety of early versus late ambulation after percutaneous coronary interventions (PCIs) using a femoral artery approach.
- Early ambulation was 2-4 hr after bed rest, with late ambulation 6-20 hr after bed rest.
- Outcomes assessed were hematoma or bleeding.
- Early ambulation was not more harmful than late ambulation.

Conclusion

- Reducing bed rest time from 6-10 hr down to 2-4 hr after PCI is safe.

Implications for Nursing Practice

- Inform nursing personnel that it is safe to ambulate patients 2-4 hr after PCI is done via a femoral artery approach.
- After PCI monitor patients for signs of bleeding at the puncture site.

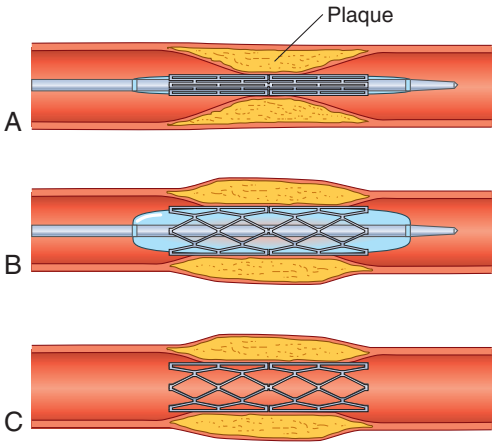

FIG. 34-6 Placement of a coronary artery stent. **A,** The stent is positioned at the site of the lesion. **B,** The balloon is inflated, expanding the stent. The balloon is then deflated and removed. **C,** The implanted stent is left in place.

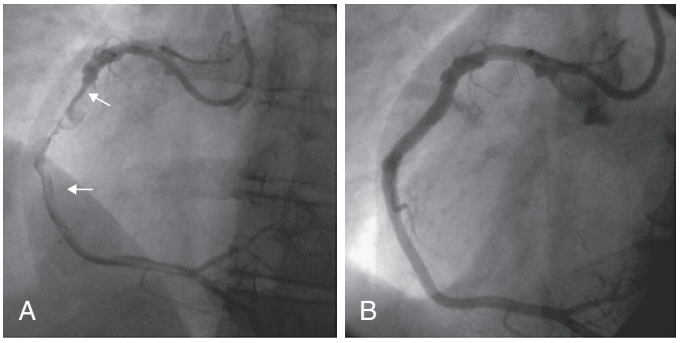

FIG. 34-7 **A,** A thrombotic occlusion of the right coronary artery is noted *(arrows).* **B,** Right coronary artery is opened and blood flow restored following angioplasty and placement of a 4-mm stent.

a catheter with an inflatable balloon tip is inserted into the appropriate coronary artery. When the blockage is located, the catheter is passed through it, the balloon is inflated, and the atherosclerotic plaque is compressed, resulting in vessel dilation. This procedure is called *balloon angioplasty.*

Intracoronary stents are often inserted in conjunction with balloon angioplasty. Stents are used to treat abrupt or threatened abrupt closure and restenosis following balloon angioplasty. A **stent** is an expandable meshlike structure designed to keep the vessel open by compressing the arterial wall (Figs. 34-6 and 34-7). Because stents are thrombogenic, unfractionated heparin (UH) or low-molecular-weight heparin (LMWH) is started to maintain the open vessel. In addition, a direct thrombin inhibitor (e.g., bivalirudin [Angiomax]) and/or a glycoprotein IIb/IIIa inhibitor (e.g., tirofiban [Aggrastat]) is also used during PCI to help prevent the abrupt closure of the stents (see Table 34-11). After PCI, the patient is treated with dual antiplatelet agents (e.g., aspirin [indefinitely] and ticagrelor [Brilinta] for 12 months) until the intimal lining can grow over the stent and provide a smooth vascular surface.

Many stents are drug-eluting stents. This type of stent is coated with a drug (e.g., paclitaxel, sirolimus) that prevents the overgrowth of new intima, the primary cause of stent restenosis. Following drug-eluting stent placement, the patient continues dual antiplatelet therapy to prevent thrombus formation on the stent. Drug therapy may continue for 12 months or longer.[18]

The most serious complications from stent placement are abrupt closure and vascular injury. Other less common complications include acute MI, stent embolization, coronary spasm, and emergent coronary artery bypass graft (CABG) surgery. The possibility of dysrhythmias during and after the procedure is always present.

PCI may not be a feasible option for all patients (e.g., patients with three-vessel CAD [three different coronary arteries] and/or significant left main coronary artery disease). Coronary revascularization with CABG surgery may be recommended and is discussed later in the chapter.

ACUTE CORONARY SYNDROME

When ischemia is prolonged and not immediately reversible, **acute coronary syndrome (ACS)** develops and encompasses the spectrum of unstable angina (UA), *non–ST-segment-elevation myocardial infarction* (NSTEMI), and *ST-segment-elevation myocardial infarction* (STEMI) (Fig. 34-8). Although each remains a distinct diagnosis, this nomenclature (ACS) reflects the relationships among the pathophysiology, presentation, diagnosis, prognosis, and interventions for these disorders.

ACS is associated with deterioration of a once stable atherosclerotic plaque. The once stable plaque ruptures, exposing the intima to blood and stimulating platelet aggregation and local vasoconstriction with thrombus formation. This unstable lesion may be partially occluded by a thrombus (manifesting as UA or NSTEMI) or totally occluded by a thrombus (manifesting as

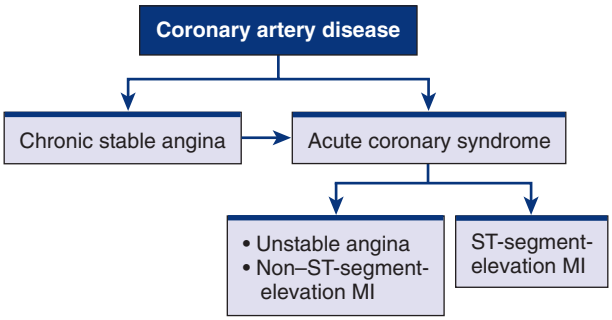

FIG. 34-8 Relationships among coronary artery disease, chronic stable angina, and acute coronary syndrome.

STEMI).[16] What causes a coronary plaque to suddenly become unstable is not well understood, but systemic inflammation (described earlier) is thought to play a role. Patients with suspected ACS require immediate hospitalization.

UNSTABLE ANGINA

Unstable angina (UA) is chest pain that is new in onset, occurs at rest, or has a worsening pattern. The patient with chronic stable angina may develop UA, or UA may be the first clinical sign of CAD. Unlike chronic stable angina, UA is unpredictable and is an emergency. The patient with previously diagnosed chronic stable angina describes a significant change in the pattern of angina. It occurs with increasing frequency and is easily provoked by minimal or no exertion, during sleep, or even at rest. The patient without previously diagnosed angina describes anginal pain that has progressed rapidly in the past few hours, days, or weeks, often ending in pain at rest.

Women seek medical attention for symptoms of UA more often than men. Despite national efforts to increase awareness, women's symptoms continue to go unrecognized as heart related. These symptoms include fatigue, shortness of breath, indigestion, and anxiety. Fatigue is the most prominent symptom. However, all these symptoms can relate to many different diseases and syndromes. Thus women often present with UA before CAD is diagnosed. (See Gender Differences box on p. 733 earlier in this chapter.)

MYOCARDIAL INFARCTION

A **myocardial infarction (MI)** occurs because of sustained ischemia, causing irreversible myocardial cell death (necrosis) (Figs. 34-9 and 34-10). Thrombus formation causes 80% to 90% of all acute MIs.[19] When a thrombus develops, there is no blood flow to the myocardium distal to the blockage, resulting in necrosis. Contractile function of the heart stops in the necrotic area(s). The degree of altered function depends on the area of the heart involved and the size of the infarction.

The acute MI process takes time. Cardiac cells can withstand ischemic conditions for approximately 20 minutes before cell death begins. The earliest tissue to become ischemic is the subendocardium (the innermost layer of tissue in the cardiac muscle). If ischemia persists, it takes approximately 4 to 6 hours for the entire thickness of the heart muscle to become necrosed. If the thrombus is not completely blocking the artery, the time to complete necrosis may be as long as 12 hours.

MIs are usually described based on the location of damage (e.g., anterior, inferior, lateral, septal, or posterior wall infarction). Most involve some portion of the left ventricle. The location of the infarction correlates with the involved coronary circulation. For example, the right coronary artery provides blood supply to the inferior wall. Blockage of the right coronary artery results in an inferior wall MI. Anterior wall infarctions result from blockages in the left anterior descending artery. Blockages in the left circumflex artery usually cause lateral and/or posterior wall MIs. Damage can occur in more than one location, especially if more than one coronary artery is involved (e.g., anterolateral MI, anteroseptal MI).

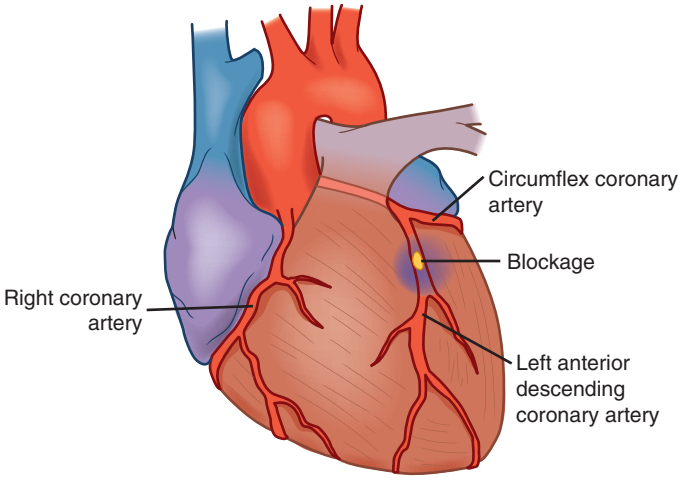

FIG. 34-9 Occlusion of the left anterior descending coronary artery, resulting in a myocardial infarction.

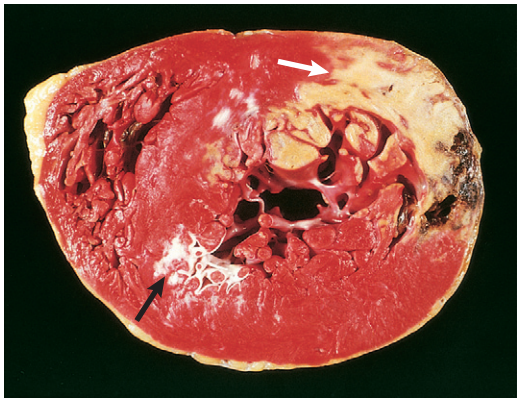

FIG. 34-10 Acute myocardial infarction in the posterolateral wall of the left ventricle. This is demonstrated by the absence of staining in the areas of necrosis *(white arrow)*. Note the scarring from a previous anterior wall myocardial infarction *(black arrow)*.

The degree of preexisting collateral circulation also influences the severity of infarction (see Fig. 34-2). An individual with a long history of CAD develops collateral circulation to provide the area surrounding the infarction site with a blood supply. This is one reason why a younger person may have a more serious first MI than an older person with the same degree of blockage.

Clinical Manifestations of Myocardial Infarction

Pain. Severe, immobilizing chest pain not relieved by rest, position change, or nitrate administration is the hallmark of an MI. Persistent and unlike any other pain, it is usually described as a heaviness, pressure, tightness, burning, constriction, or crushing. Common locations are substernal, retrosternal, or

epigastric areas. When epigastric pain is present, the patient may relate it to indigestion and take antacids without relief. The pain may radiate to the neck, lower jaw, and arms or to the back (see Fig. 34-4). It may occur while the patient is active or at rest, asleep or awake. However, it commonly occurs in the early morning hours. It usually lasts for 20 minutes or longer and is more severe than usual anginal pain.

Not everyone has classic symptoms. Some patients may not experience pain but may have "discomfort," weakness, or shortness of breath. Although women and men have more similarities than differences in their acute MI symptoms, some women may experience atypical discomfort, shortness of breath, or fatigue.[20] Patients with diabetes may experience silent (asymptomatic) MIs because of cardiac neuropathy and may manifest atypical symptoms (e.g., dyspnea). An older patient may experience a change in mental status (e.g., confusion), shortness of breath, pulmonary edema, dizziness, or a dysrhythmia.

Sympathetic Nervous System Stimulation. During the initial phase of MI, the ischemic myocardial cells release catecholamines (norepinephrine and epinephrine) that are normally found in these cells. This results in release of glycogen, diaphoresis, and vasoconstriction of peripheral blood vessels. On physical examination, the patient's skin may be ashen, clammy, and cool to touch.

Cardiovascular Manifestations. In response to the release of catecholamines, BP and HR may be elevated initially. Later, the BP may drop because of decreased cardiac output (CO). If severe enough, this may result in decreased renal perfusion and urine output. Crackles, if present, may persist for several hours to several days, suggesting left ventricular dysfunction. Jugular venous distention, hepatic engorgement, and peripheral edema may indicate right ventricular dysfunction.

Cardiac examination may reveal abnormal heart sounds that may seem distant. Other abnormal sounds suggesting ventricular dysfunction are S_3 and S_4. In addition, a loud holosystolic murmur may develop and may indicate a septal defect, papillary muscle rupture, or valve dysfunction.

Nausea and Vomiting. The patient may experience nausea and vomiting. These symptoms can result from reflex stimulation of the vomiting center by the severe pain. They can also result from vasovagal reflexes initiated from the area of the infarcted myocardium.

Fever. The temperature may increase within the first 24 hours up to 100.4° F (38° C). The temperature elevation may last for as long as 1 week. This increase in temperature is due to a systemic inflammatory process caused by myocardial cell death.

Healing Process

The body's response to cell death is the inflammatory process (see Chapter 12). Within 24 hours, leukocytes infiltrate the area. The dead cardiac cells release enzymes that are important diagnostic indicators of MI. (See Serum Cardiac Markers later in this chapter.) The proteolytic enzymes of the neutrophils and macrophages begin to remove necrotic tissue by the fourth day. During this time the necrotic muscle wall is thin. The development of collateral circulation improves areas of poor perfusion and may limit the zones of injury and infarction. Once infarction takes place, catecholamine-mediated lipolysis and glycogenolysis occur. These processes allow the increased plasma glucose and free fatty acids to be used by the oxygen-depleted myocardium for anaerobic metabolism. For this reason, serum glucose levels are frequently elevated after MI.[19]

The necrotic zone is identifiable by ECG changes (e.g., ST segment elevation, pathologic Q wave) and by nuclear scanning after the onset of symptoms. At this point, the neutrophils and monocytes have cleared the necrotic debris from the injured area, and the collagen matrix that will eventually form scar tissue is laid down.

At 10 to 14 days after MI, the new scar tissue is still weak. The myocardium is vulnerable to increased stress during this time because of the unstable state of the healing heart wall. At the same time the patient's activity level may be increasing, so special caution and assessment are necessary. By 6 weeks after MI, scar tissue has replaced necrotic tissue and the injured area is considered healed. The scarred area is often less compliant than the surrounding area. This condition may be manifested by uncoordinated wall motion, ventricular dysfunction, altered conduction patterns, or heart failure (HF).

These changes in the infarcted muscle also cause changes in the unaffected myocardium. In an attempt to compensate for the damaged muscle, the normal myocardium hypertrophies and dilates. This process is called *ventricular remodeling*. Remodeling of normal myocardium can lead to the development of late HF, especially in the individual with atherosclerosis of other coronary arteries and/or an anterior MI.

Complications of Myocardial Infarction

Dysrhythmias. The most common complication after an MI is dysrhythmias, which are present in 80% to 90% of patients. Dysrhythmias are the most common cause of death in patients in the prehospital period. Any condition that affects the myocardial cell's sensitivity to nerve impulses (e.g., ischemia, electrolyte imbalances, SNS stimulation) can cause dysrhythmias. The intrinsic rhythm of the heart is disrupted. This can cause tachycardia, bradycardia, or an irregular HR, all of which adversely affect the ischemic myocardium.

Life-threatening dysrhythmias occur most often with anterior wall infarction, HF, or shock. Complete heart block develops when key portions of the conduction system are destroyed. Ventricular fibrillation, a common cause of sudden cardiac death (SCD), is a lethal dysrhythmia. It most often occurs within the first 4 hours after the onset of pain. Premature ventricular contractions may precede ventricular tachycardia and fibrillation. Life-threatening ventricular dysrhythmias must be treated immediately. (See Chapter 36 for a detailed description of dysrhythmias and their management.)

Heart Failure. *Heart failure* (HF) is a complication that occurs when the heart's pumping action is reduced. Depending on the severity and extent of the injury, HF occurs initially with subtle signs such as mild dyspnea, restlessness, agitation, or slight tachycardia. Other signs indicating the onset of HF include pulmonary congestion on chest x-ray, S_3 or S_4 heart sounds on auscultation, crackles on auscultation of breath sounds, and jugular venous distention. (The treatment of acute decompensated HF is discussed in Chapter 35.)

Cardiogenic Shock. *Cardiogenic shock* occurs when oxygen and nutrients supplied to the tissues are inadequate because of severe left ventricular failure. This occurs less often with the early and rapid treatment of MI with PCI or thrombolytic therapy. When cardiogenic shock does occur, it has a high mortality rate. Cardiogenic shock requires aggressive management. This includes control of dysrhythmias, intraaortic balloon pump (IABP) therapy, and support of contractility with vasoactive drugs. Goals of therapy are to maximize oxygen

delivery, reduce oxygen demand, and prevent complications (e.g., acute kidney injury). (Cardiogenic shock is discussed in Chapter 67.)

Papillary Muscle Dysfunction. *Papillary muscle dysfunction* may occur if the infarcted area includes or is near the papillary muscle that attaches to the mitral valve (see Fig. 32-2). You should suspect papillary muscle dysfunction if you auscultate a new murmur at the cardiac apex. An echocardiogram confirms the diagnosis.

Papillary muscle rupture is a rare and life-threatening complication. It causes massive mitral valve regurgitation. Dyspnea, pulmonary edema, and decreased CO result from the back up of blood in the left atrium. This condition aggravates an already damaged left ventricle by reducing CO even further. The patient undergoes rapid clinical deterioration. Treatment includes rapid afterload reduction with nitroprusside (Nipride) and/or IABP therapy, and immediate cardiac surgery with mitral valve repair or replacement.[19] (See Chapter 37 for discussion of valve disorders.)

Ventricular Aneurysm. *Ventricular aneurysm* results when the infarcted myocardial wall is thin and bulges out during contraction. This can develop within a few days, weeks, or months. The patient with a ventricular aneurysm may experience HF, dysrhythmias, and angina. Besides ventricular rupture, which is fatal, ventricular aneurysms harbor thrombi that can lead to an embolic stroke.

Pericarditis. *Acute pericarditis,* an inflammation of the visceral and/or parietal pericardium, may result in cardiac tamponade, decreased ventricular filling and emptying, and HF. It occurs 2 or 3 days after an acute MI as a common complication of the infarction. Pericarditis is characterized by chest pain, which may vary from mild to severe and is aggravated by inspiration, coughing, and movement of the upper body. Sitting in a forward position often relieves the pain. The pain is usually different from pain associated with an MI.

Assess the patient with suspected pericarditis for the presence of a friction rub over the pericardium. The sound may be best heard with the diaphragm of the stethoscope at the mid to lower left sternal border. It may be persistent or intermittent. Fever may also be present. The patient may have hypotension and/or a narrow pulse pressure.

Diagnosis of pericarditis can be made with serial 12-lead ECGs. Typical ECG changes include diffuse ST-segment elevations. This reflects the inflammation of the pericardium. Treatment includes pain relief with NSAIDs, aspirin, or corticosteroids. (Chapter 37 discusses pericarditis.)

Dressler Syndrome. *Dressler syndrome* is pericarditis with effusion and fever that develops 4 to 6 weeks after MI. It may also occur after cardiac surgery. It is thought to be caused by an antigen-antibody reaction to the necrotic myocardium. The patient experiences pericardial pain, fever, a friction rub, pericardial effusion, and arthralgia. Laboratory findings include an elevated white blood cell count and sedimentation rate. Short-term corticosteroids are used to treat this condition.

DIAGNOSTIC STUDIES ACUTE CORONARY SYNDROME

In addition to the patient's history of pain, risk factors, and health history, the primary diagnostic studies used to determine whether a person has UA or an MI include an ECG and serum cardiac markers (see Fig. 34-5).

Electrocardiogram Findings

The ECG is one of the primary tools to diagnose UA or an MI. Changes in the QRS complex, ST segment, and T wave caused by ischemia and infarction can develop quickly with UA and MI. For diagnostic and treatment purposes, it is important to distinguish between STEMI and UA or NSTEMI. Patients with STEMI tend to have a more extensive MI that is associated with prolonged and complete coronary occlusion; a pathologic Q wave is seen on the ECG. Patients with UA or NSTEMI usually have transient thrombosis or incomplete coronary occlusion and usually do not develop pathologic Q waves. Because MI is a dynamic process that evolves with time, the ECG often reveals the time sequence of ischemia, injury, infarction, and resolution of the infarction.

The ECG must be read carefully, since changes can be subtle at first. It may also be normal or nondiagnostic when the patient comes to the ED with a complaint of chest pain. Within a few hours, the ECG may change to reflect the infarction process. For this reason, when the initial 12-lead ECG is nondiagnostic, serial 12-lead ECGs are done. (See Chapter 36 for discussion of ECG changes associated with ischemia and MI.)

Serum Cardiac Markers

Serum cardiac markers are proteins released into the blood from necrotic heart muscle after an MI (see Table 32-6). These markers are important in the diagnosis of MI. The onset, peak, and duration of levels of these markers are shown in Fig. 34-11.

Cardiac-specific troponin has two subtypes: cardiac-specific troponin T (cTnT) and cardiac-specific troponin I (cTnI). These markers are highly specific indicators of MI and have greater sensitivity and specificity for myocardial injury than creatine kinase (CK) MB (CK-MB). Serum levels of cTnI and cTnT increase 4 to 6 hours after the onset of MI, peak at 10 to 24 hours, and return to baseline over 10 to 14 days.

CK levels begin to rise about 6 hours after an MI, peak at about 18 hours, and return to normal within 24 to 36 hours. The CK enzymes are fractionated into bands. The CK-MB band is specific to myocardial cells and also helps quantify myocardial damage.

Myoglobin is released into the circulation within 2 hours after an MI and peaks in 3 to 15 hours. Although it is one of

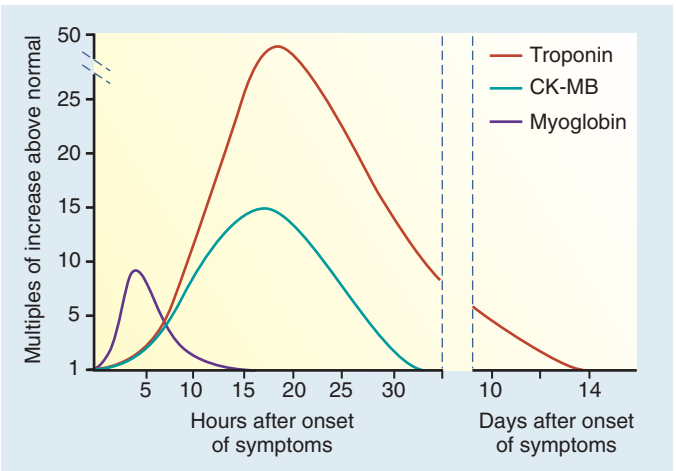

FIG. 34-11 Serum cardiac markers found in the blood after myocardial infarction.

TABLE 34-12 EMERGENCY MANAGEMENT

Chest Pain

Etiology

Cardiovascular
- Myocardial ischemia
- Myocardial infarction
- Dysrhythmia
- Pericarditis
- Aortic aneurysm
- Aortic valve disease

Respiratory
- Costochondritis
- Pleurisy
- Pneumonia
- Pneumothorax, hemothorax
- Pulmonary edema
- Pulmonary embolus

Chest Trauma
- Rib/sternal fracture
- Flail chest
- Cardiac tamponade
- Hemothorax
- Pulmonary contusion
- Great vessel injury

Gastrointestinal
- Esophagitis
- GERD
- Hiatal hernia
- Peptic ulcer
- Cholecystitis

Others
- Stress
- Strenuous exercise
- Drugs (e.g., cocaine)
- Acute anxiety

Assessment Findings

- Pain in chest, neck, jaw, arm, or shoulder
- Cold, clammy skin
- Diaphoresis
- Nausea and vomiting
- Epigastric pain
- Indigestion, heartburn
- Dyspnea, tachypnea
- Weakness
- Anxiety
- Feeling of impending doom
- Tachycardia, bradycardia
- Irregular HR, murmurs
- Palpitations
- Dysrhythmias
- Decreased or increased BP
- Narrowed pulse pressure
- Unequal BP readings in upper extremities
- Syncope, loss of consciousness
- Decreased O_2 saturation
- Decreased or absent breath sounds
- Pericardial friction rub

Interventions

Initial
- Assess ABCs.
- Position patient upright unless contraindicated and administer O_2 by nasal cannula or non-rebreather mask.
- Obtain baseline vital signs, including O_2 saturation.
- Auscultate heart and breath sounds.
- Obtain 12-lead ECG.
- Insert two IV catheters.
- Assess pain using PQRST mnemonic (see Table 34-7).
- Medicate for pain as ordered (e.g., nitroglycerin, morphine).
- Initiate continuous ECG monitoring and identify underlying rhythm.
- Obtain baseline blood work (e.g., cardiac markers, serum electrolytes).
- Obtain portable chest x-ray.
- Assess for contraindications for antiplatelet, anticoagulant, or thrombolytic therapy, or PCI as appropriate.
- Administer aspirin for cardiac-related chest pain unless contraindicated.
- Administer antidysrhythmic drugs as indicated.

Ongoing Monitoring
- Monitor ABCs, vital signs, level of consciousness, heart and breath sounds, cardiac rhythm, and O_2 saturation.
- Assess and record response to medications (e.g., decrease in chest pain) and remedicate or titrate medications (e.g., nitroglycerin) as needed.
- Provide reassurance and emotional support to patient and caregiver.
- Explain all interventions and procedures to patient and caregiver in simple terms.
- Anticipate need for intubation if respiratory distress is evident.
- Prepare for CPR and defibrillation if cardiac arrest is evident.
- Anticipate need for transcutaneous pacing for symptomatic bradycardia or heart block.

ABCs, Airway, breathing, circulations; *GERD,* gastroesophageal reflux disease; *PCI,* percutaneous coronary intervention.

the first serum cardiac markers to appear after an MI, it lacks cardiac specificity. Its role in diagnosing MI is limited.

Coronary Angiography

The patient with UA or NSTEMI may or may not undergo coronary angiography to evaluate the extent of the disease. Guidelines suggest that it is reasonable to do coronary angiography on stable but high-risk patients with UA or NSTEMI. If appropriate, a PCI is performed at this time. Some patients may be treated with conservative medical management.[21,22] Coronary angiography is the only way to confirm the diagnosis of Prinzmetal's angina.

Other Measures

When the ECG and serum cardiac markers do not confirm MI, other measures for diagnosing UA are considered (see Table 32-6). Exercise or pharmacologic stress testing and echocardiogram are used when a patient has an abnormal but nondiagnostic baseline ECG. A dobutamine (Dobutrex), dipyridamole (Persantine), or adenosine (Adenocard) stress echocardiogram simulates the effects of exercise and is used in patients unable to exercise. (See Chapter 32 for additional information on cardiac assessment.)

COLLABORATIVE CARE ACUTE CORONARY SYNDROME

It is extremely important to rapidly diagnose and treat a patient with ACS to preserve cardiac muscle. Initial management of the patient with chest pain most often occurs in the ED. Table 34-12 presents the emergency care of the patient with chest pain. Obtain a 12-lead ECG and start continuous ECG monitoring. Position the patient in an upright position unless contraindicated, and initiate oxygen by nasal cannula to keep oxygen saturation above 93%. Establish an IV route to provide an access for emergency drug therapy. Give SL NTG and aspirin (chewable) if not given before arrival at the ED. Morphine sulfate is given for pain unrelieved by NTG. The patient usually receives ongoing care in a critical care unit or telemetry unit, where continuous ECG monitoring is available. Dysrhythmias are treated according to established protocols. Fig. 34-5 on p. 743 presents the collaborative care of ACS.

Monitor vital signs, including pulse oximetry, frequently during the first few hours after admission and closely thereafter. Maintain bed rest and limit activity for 12 to 24 hours, with a gradual increase in activity unless contraindicated.

For patients with ongoing angina and negative cardiac markers, dual antiplatelet therapy (e.g., aspirin and ticagrelor) and heparin (UH or LMWH) is recommended. Coronary angiography with possible PCI is considered once the patient is stabilized and angina is controlled, or if angina returns or increases in severity.[21]

For patients with STEMI or NSTEMI with positive cardiac markers, reperfusion therapy is initiated (see Figs. 34-6 and 34-7). *Reperfusion therapy* can include emergent PCI for STEMI and NSTEMI or thrombolytic (fibrinolytic) therapy for STEMI. Coronary surgical revascularization is considered for select patients (e.g., patients with diabetes and three-vessel disease [involvement of three different coronary arteries]). The goal in the treatment of MI is to salvage as much myocardial muscle as possible.

Emergent PCI

Emergent PCI is the first line of treatment for patients with confirmed MI (i.e., definitive ECG changes and/or positive cardiac markers).[23] The goal is to open the blocked artery within 90 minutes of arrival to a facility that has an interventional cardiac catheterization laboratory. In this situation the patient undergoes a cardiac catheterization to locate the blockage(s), assess the severity of the blockage(s), determine the presence of collateral circulation, and evaluate left ventricular function. During the procedure, treatment modalities (e.g., placement of drug-eluting stents) are selected. Patients with severe left ventricular dysfunction may require the addition of intraaortic balloon pump (IABP) therapy, and a small percentage of patients may require emergent CABG surgery.

The advantages of PCI include the following: (1) it provides an alternative to surgical intervention; (2) it is performed with local anesthesia; (3) the patient is ambulatory shortly after the procedure; (4) the length of hospital stay is approximately 1 to 3 days compared with the 4- to 6-day stay with CABG surgery, thus reducing hospital costs; and (5) the patient can return to work several weeks sooner after PCI, compared with a 6- to 8-week convalescence after CABG.

Advances in PCI techniques have significantly reduced the need for emergent CABG. Currently, more PCIs are performed than CABGs.[1] The most serious complication of PCI is dissection of the newly dilated coronary artery.[22] If the damage is extensive, the coronary artery could rupture, causing cardiac tamponade, ischemia and infarction, decreased CO, and possible death. There is also a danger that the infarction could be extended should a portion of the plaque dislodge and block the vessel distal to the catheter. Coronary spasm from the mechanical irritation of the catheter or balloon can occur, as well as chemical irritation from the contrast medium used to see the artery. Abrupt closure is a complication that can occur in the first 24 hours after PCI. Restenosis can also occur. Risk is greatest in the first 30 days after PCI. Nursing care of the patient following PCI is similar to that after cardiac catheterization (see Table 32-6).

Thrombolytic Therapy

Thrombolytic therapy offers the advantages of availability and rapid administration in facilities that do not have an interventional cardiac catheterization laboratory or when one is too far away to transfer the patient safely.[23] Treatment of MI with thrombolytic therapy aims to stop the infarction process by dissolving the thrombus in the coronary artery and reperfusing the myocardium. Thrombolytic therapy is given as soon as possible, ideally within the first hour and preferably within the first 6 hours after the onset of symptoms. Mortality is reduced by 25% if reperfusion occurs within 6 hours.[18,19]

Indications and Contraindications. All thrombolytics are given IV (see Table 34-11). The cost, efficacy, and ease of administration guide the choice of a thrombolytic agent. Although these drugs have different pharmacokinetics, they all open the blocked artery by lysis of the thrombus. The goal is to administer a thrombolytic within 30 minutes of the patient's arrival to a facility without an interventional cardiac catheterization laboratory. (PCI is first-line therapy in a facility with an interventional cardiac catheterization laboratory, as discussed above.)

Because all thrombolytics lyse the pathologic clot, they may also lyse other clots (e.g., a postoperative site). Therefore patient selection is important because minor or major bleeding can be a complication of therapy.[18] Inclusion criteria for thrombolytic therapy include (1) chest pain typical of acute MI 6 hours or less in duration, (2) 12-lead ECG findings consistent with acute MI, and (3) no absolute contraindications (Table 34-13). Although patients with chest pain lasting more than 6 hours and ECG changes supporting MI may be considered for thrombolytic therapy, benefits of this therapy are inconsistent.

Procedure. Each hospital has a protocol for giving thrombolytic therapy, but several factors are common. Draw blood to obtain baseline laboratory values and start two or three lines for IV therapy. All other invasive procedures are done before the thrombolytic agent is given to reduce the possibility of bleeding.

Depending on the drug selected, therapy is administered in one IV bolus or over time (30 to 90 minutes). Note the time at which therapy begins, and monitor the patient during and after administration of the thrombolytic. Evaluate heart rhythm, vital signs, and pulse oximetry and assess the heart and lungs frequently to evaluate the patient's response to therapy. Regularly assess for changes in neurologic status, since this may indicate a cerebral bleed.

TABLE 34-13 CONTRAINDICATIONS FOR THROMBOLYTIC THERAPY

Absolute Contraindications

- Active internal bleeding or bleeding diathesis (excluding menstruation)
- Known history of cerebral aneurysm or arteriovenous malformation
- Known intracranial neoplasm (primary or metastatic)
- Previous cerebral hemorrhage
- Recent (within past 3 mo) ischemic stroke
- Significant closed-head or facial trauma within past 3 mo
- Suspected aortic dissection

Relative Contraindications and Cautions

- Active peptic ulcer disease
- Current use of anticoagulants
- Pregnancy
- Prior ischemic stroke (>3 mo ago), dementia, or known intracranial pathologic condition not covered in absolute contraindications
- Recent (within 3 wk) surgery (including eye laser surgery) or puncture of noncompressible vessel
- Recent (within 2-4 wk) internal bleeding
- Serious systemic disease (e.g., advanced or terminal cancer, severe liver or kidney disease)
- Severe uncontrolled hypertension (BP >180/110 mm Hg) on presentation or chronic severe poorly controlled hypertension
- Traumatic or prolonged (>10 min) cardiopulmonary resuscitation

When reperfusion occurs (i.e., the coronary artery that was blocked is opened and blood flow is restored to the myocardium), several clinical markers may be seen. The most reliable marker is the return of the ST segment to baseline on the ECG. Other markers include a resolution of chest pain and an early, rapid rise of the serum cardiac markers within 3 hours of therapy, peaking within 12 hours. These levels increase as the necrotic myocardial cells release proteins into the circulation after perfusion is restored to the area. The presence of *reperfusion dysrhythmias* (e.g., accelerated idioventricular rhythm) is a less reliable marker of reperfusion. These dysrhythmias are generally self-limiting and do not require aggressive treatment. (See Chapter 36 for management of dysrhythmias.)

A major concern with thrombolytic therapy is reocclusion of the artery. The site of the thrombus is unstable, and formation of another clot or spasm of the artery may occur. Because of this possibility, IV heparin therapy is initiated. If another clot develops, the patient will have similar complaints of chest pain, and ECG changes will return. Patients receiving thrombolytic therapy should be transferred to a facility with PCI capabilities as soon as possible. This way, PCI can be performed if thrombolytic therapy fails.[18]

The major complication with thrombolytic therapy is bleeding. Ongoing nursing assessment is essential. Minor bleeding (e.g., surface bleeding from IV sites or gingival bleeding) is expected and controlled by applying a pressure dressing or ice packs.

SAFETY ALERT

- When thrombolytic therapy is used, bleeding may occur.
- If signs and symptoms of major bleeding occur (e.g., drop in BP, an increase in HR, a sudden change in the patient's level of consciousness, blood in the urine or stool), stop the therapy and notify the physician.

Coronary Surgical Revascularization

Coronary revascularization with CABG surgery is recommended for patients who (1) fail medical management, (2) have left main coronary artery or three-vessel disease, (3) are not candidates for PCI (e.g., lesions are long or difficult to access), (4) have failed PCI and continue to have chest pain, (5) have diabetes mellitus, or (6) are expected to have longer term benefits with CABG than with PCI.[24]

Coronary Artery Bypass Graft Surgery. CABG surgery consists of the placement of conduits to transport blood between the aorta, or other major arteries, and the myocardium distal to the blocked coronary artery (or arteries). The procedure may involve one or more grafts using the internal mammary artery, saphenous vein, radial artery, gastroepiploic artery, and/or inferior epigastric artery (Fig. 34-12).

CABG surgery requires a sternotomy (opening of the chest cavity) and *cardiopulmonary bypass* (CPB). During CPB, blood is diverted from the patient's heart to a machine where it is oxygenated and returned (via a pump) to the patient. This allows the surgeon to operate on a quiet, nonbeating, bloodless heart while perfusion to vital organs is maintained.

The internal mammary artery (IMA) is the most common artery used for bypass graft. It is left attached to its origin (the subclavian artery) but then dissected from the chest wall. Next, it is *anastomosed* (connected with sutures) to the coronary artery distal to the blockage. The long-term patency rate for IMA grafts is greater than 90% after 10 years.[24]

Saphenous veins are also used for bypass grafts. The surgeon removes the saphenous vein from one or both legs endoscopically. Sections are attached to the ascending aorta and then to a coronary artery distal to the blockage. Saphenous vein grafts do develop diffuse intimal hyperplasia. This contributes to future stenosis and graft occlusions. The use of antiplatelet therapy and statins after surgery improves vein graft patency. Patency rates of these grafts are 50% to 60% at 10 years.[24]

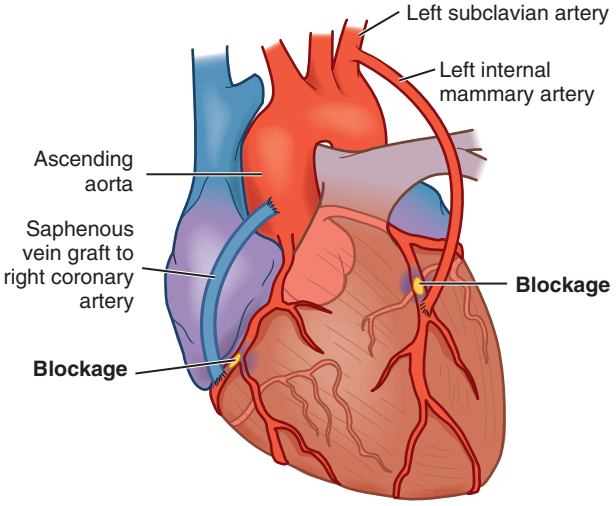

FIG. 34-12 Distal end of the left internal mammary artery is grafted below the area of blockage in the left anterior descending artery. Proximal end of the saphenous vein is grafted to the aorta, and the distal end is grafted below the area of blockage in the right coronary artery.

The radial artery is another conduit that can be used. It is a thick muscular artery that is prone to spasm. Perioperative calcium channel blockers and long-acting nitrates can control the spasms. Patency rates at 5 years are as high as 84%. There have been no reports of extremity complications (e.g., hand ischemia, wound infection) after removal of this artery.[24]

Other potential conduits include the gastroepiploic or inferior epigastric artery. However, they are rarely used, since the dissection of these arteries is extensive. This increases the length of surgery and the risk for wound complications at the harvest site, especially in an obese or diabetic patient.[24] Like the radial artery, these are also prone to spasms. One-year patency rate for the epigastric artery is 90%, and 10-year patency rate for the gastroepiploic artery is 62%.[24]

CABG surgery remains a palliative treatment for CAD and not a cure. Studies have shown improved patient outcomes, quality of life, and survival after CABG surgery. However, postoperative complications and mortality increase with age.

Women have higher operative mortality rates than men. This has been attributed to the late treatment of CAD in women because women first present with the disease at an older age and are more ill (e.g., decreased left ventricular function) at the time of surgery. Other possible factors include smaller-diameter coronary vessels and the less frequent use of the IMA.

Minimally Invasive Direct Coronary Artery Bypass. *Minimally invasive direct coronary artery bypass* (MIDCAB) offers patients with limited disease an approach to surgical treatment that does not involve a sternotomy and CPB. In many cases these patients are too high risk for traditional bypass surgery.[25] The technique requires several small incisions between the ribs. A thoracoscope is used to dissect the IMA. The heart is slowed using a β-adrenergic blocker (e.g., esmolol [Brevibloc]) or stopped temporarily with adenosine. A mechanical stabilizer immobilizes the operative site. The IMA is then sutured to the left anterior descending or right coronary artery. A radial artery or saphenous vein graft can be used if the IMA is not available.

Off-Pump Coronary Artery Bypass. The *off-pump coronary artery bypass* (OPCAB) procedure uses full or partial sternotomy to access all coronary vessels. OPCAB is performed on a beating heart using mechanical stabilizers and without CPB. It is usually reserved for patients who have limited disease but are at high risk for traditional surgery secondary to multiple co-morbidities. Patients who are typically candidates for OPCAB have a very low EF, severe lung disease, acute or chronic kidney disease, a high risk for stroke, or a calcified aorta.[25]

Robot-Assisted Cardiothoracic Surgery. This technique incorporates the use of a robot in performing CABG or mitral valve replacement. The benefits of robotic surgery include increased precision, smaller incisions, decreased blood loss, less pain, and shorter recovery time.

Transmyocardial Laser Revascularization. *Transmyocardial laser revascularization* (TMR) is an indirect revascularization procedure. It is used for patients with advanced CAD who are not candidates for traditional CABG surgery and who have persistent angina after maximum medical therapy. The procedure involves the use of a high-energy laser to create channels in the heart to allow blood flow to ischemic areas. The procedure is performed during cardiac catheterization as a percutaneous TMR or during surgery using a left anterior thoracotomy incision as an adjunct to CABG.

Drug Therapy

IV NTG, dual antiplatelet therapy (e.g., aspirin and clopidogrel), and systemic anticoagulation with either LMWH given subcutaneously or IV UH are the initial drug treatments of choice for ACS.[18,19] IV direct thrombin inhibitors may also be used if PCI is anticipated. Oral β-adrenergic blockers are given within the first 24 hours of a STEMI if there are no contraindications (e.g., HF, heart block, hypotension). ACE inhibitors are added for select patients following MI (discussed below). Calcium channel blockers or long-acting nitrates are added if the patient is already taking adequate doses of β-adrenergic blockers, cannot tolerate β-adrenergic blockers, or has Prinzmetal's angina.[18,19]

Table 34-11 and Fig. 34-5 present drug therapy for patients with ACS. These drugs are discussed on pp. 743 and 745. ACS-specific discussion of select drugs is presented in this section.

IV Nitroglycerin. IV NTG (Tridil) is used in the initial treatment of the patient with ACS. The goal of therapy is to reduce anginal pain and improve coronary blood flow. IV NTG decreases preload and afterload while increasing the myocardial oxygen supply. The onset of action is immediate. Titrate NTG to control and stop chest pain. Because hypotension is a common side effect, closely monitor BP during this time. Patients who do become hypotensive are often volume depleted and can benefit from an IV fluid bolus. Tolerance is another side effect of IV nitrate therapy. An effective strategy for this phenomenon is to titrate the dose down at night during sleep and titrate the dose up during the day.

Morphine Sulfate. Morphine sulfate is the drug of choice for chest pain that is unrelieved by NTG. As a vasodilator, it decreases cardiac workload by lowering myocardial oxygen consumption, reducing contractility, and decreasing BP and HR. In addition, morphine can help reduce anxiety and fear. In rare situations, morphine can depress respirations. Monitor patients for signs of bradypnea or hypotension, conditions to avoid in myocardial ischemia and infarction.

β-Adrenergic Blockers. β-Adrenergic blockers decrease myocardial oxygen demand by reducing HR, BP, and contractility. The use of these drugs in patients who are not at risk for complications of MI (e.g., cardiogenic shock) reduces the risk of reinfarction and the occurrence of HF. The continuation of β-adrenergic blockers indefinitely is recommended.[23] (See Table 34-11, Chapter 33, and Table 33-7 for a discussion of β-adrenergic blockers.)

Angiotensin-Converting Enzyme Inhibitors. ACE inhibitors should be started within the first 24 hours and continued indefinitely in patients recovering from STEMI of the anterior wall, with heart failure, or an EF of 40% or less.[18] The use of ACE inhibitors can help prevent ventricular remodeling and prevent or slow the progression of HF. For patients who cannot tolerate ACE inhibitors, angiotensin II receptor blockers should be considered (see Table 34-12 and Table 33-7).

Antidysrhythmic Drugs. Dysrhythmias are the most common complications after an MI. In general, they are self-limiting and are not treated aggressively unless they are life threatening (e.g., sustained ventricular tachycardia). (Chapter 36 discusses the drugs used in the treatment of dysrhythmias.)

Lipid-Lowering Drugs. A fasting lipid panel is obtained on all patients admitted with ACS. All patients with elevated triglycerides and LDL cholesterol should receive lipid-lowering drugs (see Table 34-5).

Stool Softeners. After an MI, the patient may be predisposed to constipation because of bed rest and opioid administration. Stool softeners (e.g., docusate sodium [Colace]) are given to facilitate bowel movements. This prevents straining and the resultant vagal stimulation from the Valsalva maneuver. Vagal stimulation produces bradycardia and can provoke dysrhythmias.

Nutritional Therapy

Initially, patients may be NPO (nothing by mouth) except for sips of water until stable (e.g., pain free, nausea resolved). Advance the diet as tolerated to a low-salt, low-saturated-fat, and low-cholesterol diet (see Tables 34-3 and 34-4).

NURSING MANAGEMENT CHRONIC STABLE ANGINA AND ACUTE CORONARY SYNDROME

NURSING ASSESSMENT

Table 34-14 presents the subjective and objective data to obtain from a patient with ACS.

NURSING DIAGNOSES

Nursing diagnoses for the patient with ACS may include, but are not limited to, those presented in Nursing Care Plan 34-1.

PLANNING

The overall goals for a patient with ACS include (1) relief of pain, (2) preservation of myocardium, (3) immediate and appropriate treatment, (4) effective coping with illness-associated anxiety, (5) participation in a rehabilitation plan, and (6) reduction of risk factors. In addition, the Joint Commission has identified core measures in the management of patients with an acute MI to reflect standards of evidence-based care (available at *www.jointcommission.org/assets/1/6/Acute%20Myocardial%20Infarction.pdf*).

NURSING IMPLEMENTATION: CHRONIC STABLE ANGINA

HEALTH PROMOTION. Behaviors to reduce the risk for CAD are presented in Table 34-2 and discussed on pp. 735-740.

TABLE 34-14 NURSING ASSESSMENT

Acute Coronary Syndrome

Subjective Data

Important Health Information

Past health history: Previous history of CAD, chest pain/angina, MI, valve disease (e.g., aortic stenosis), heart failure, or cardiomyopathy; hypertension, diabetes, anemia, lung disease; hyperlipidemia

Medications: Use of antiplatelets or anticoagulants, nitrates, angiotensin-converting enzyme inhibitors, β-blockers, calcium channel blockers; antihypertensive drugs; lipid-lowering drugs; over-the-counter drugs (e.g., vitamin and herbal supplements)

History of present illness: Description of events related to current illness, including any self-treatments and response (see Table 34-8)

Functional Health Patterns

Health perception–health management: Family history of heart disease; sedentary lifestyle; tobacco use; exposure to environmental smoke

Nutritional-metabolic: Indigestion, heartburn, nausea, belching, vomiting

Elimination: Urinary urgency or frequency, straining at stool

Activity-exercise: Palpitations, dyspnea, dizziness, weakness

Cognitive-perceptual: Substernal chest pain or pressure (squeezing, constricting, aching, sharp, tingling), possible radiation to jaw, neck, shoulders, back, or arms (see Table 34-7)

Coping–stress tolerance: Stressful lifestyle, depression; anger, anxiety; feeling of impending doom

Objective Data

General

Anxious, fearful, restless, distressed

Integumentary

Cool, clammy, pale skin

Cardiovascular

Tachycardia or bradycardia, pulsus alternans (alternating weak and strong heartbeats), pulse deficit, dysrhythmias (especially ventricular), S_3, S_4, ↑ or ↓ BP, murmur

Possible Diagnostic Findings

Positive serum cardiac markers, ↑ serum lipids; ↑ WBC count; positive exercise or pharmacologic stress test and thallium scans; pathologic Q wave, ST-segment elevation, and/or T wave abnormalities on ECG; cardiac enlargement, calcifications, or pulmonary congestion on chest x-ray; abnormal wall motion with stress echocardiogram; positive coronary angiography

ACUTE INTERVENTION. If your patient experiences angina, institute the following measures: (1) position patient upright unless contraindicated and administer supplemental oxygen, (2) assess vital signs, (3) obtain a 12-lead ECG, (4) provide prompt pain relief first with a nitrate followed by an opioid analgesic if needed, and (5) auscultate heart and breath sounds. The patient will most likely be distressed and may have pale, cool, clammy skin. The BP and HR may be elevated. Auscultation of the heart may reveal an atrial (S_4) or a ventricular (S_3) gallop. A new murmur heard during an anginal attack may indicate ischemia of a papillary muscle of the mitral valve. The murmur is likely to be transient and disappear when symptoms stop.

Ask the patient to describe the pain and to rate it on a scale of 0 to 10 before and after treatment to evaluate the effectiveness of the interventions (see Table 34-7). It is important to use the same words that patients use to describe their pain. Some patients may not report pain. Assess for other manifestations of pain, such as restlessness; ECG changes; elevated HR, respiratory rate, or BP; clutching of the bed linens; or other nonverbal cues. Supportive and realistic assurance and a calm approach help reduce the patient's anxiety during an anginal attack.

AMBULATORY AND HOME CARE. Reassure the patient with a history of angina that a long, active life is possible. Prevention of angina is preferable to its treatment, and this is why teaching is important. Provide the patient with information regarding CAD, angina, precipitating factors for angina, risk factor reduction, and medications.

Patient teaching can be done in a variety of ways. One-on-one contact between you and the patient is often the most effective approach. Time spent providing daily care (e.g., administering medications) offers many teachable moments. Teaching tools such as DVDs or CDs, heart models, and printed information are important components of patient and caregiver teaching (see Chapter 4).

Assist the patient to identify factors that precipitate angina (see Table 34-8). Instruct the patient on how to avoid or control precipitating factors. For example, teach the patient to avoid exposure to extremes of weather and the consumption of large, heavy meals. If a heavy meal is eaten, instruct the patient to rest for 1 to 2 hours after the meal because blood is shunted to the GI tract to aid digestion and absorption.

Assist the patient to identify personal risk factors for CAD. Then discuss the various methods of decreasing any modifiable risk factors (see Table 34-2). Teach the patient and caregiver about diets that are low in salt and saturated fats (see Tables 34-3 and 34-4). Maintaining ideal body weight is important in controlling angina because excess weight increases myocardial workload.

Adhering to a regular, individualized program of physical activity that conditions rather than overstresses the heart is important. For example, advise patients to walk briskly on a flat surface at least 30 minutes a day, most days of the week (minimum 5) if not contraindicated.[6]

It is important to teach the patient and caregiver the proper use of NTG (see pp. 743 and 745). NTG may be used prophylactically before an emotionally stressful situation, sexual intercourse, or physical exertion (e.g., climbing a long flight of stairs).

If needed, arrange for counseling to assess the psychologic adjustment of the patient and caregiver to the diagnosis of CAD and the resulting angina. Many patients feel a threat to their identity and self-esteem and may be unable to fill their usual roles in society. These emotions are normal and real.

NURSING IMPLEMENTATION ACUTE CORONARY SYNDROME

ACUTE INTERVENTION. Priorities for nursing interventions in the initial phase of ACS include (1) pain assessment and relief, (2) physiologic monitoring, (3) promotion of rest and comfort, (4) alleviation of stress and anxiety, and (5) understanding of the patient's emotional and behavioral reactions. Patients with increased anxiety levels have a greater risk for adverse outcomes such as recurrent ischemic events and dysrhythmias.[2,12] Proper management of these priorities decreases the oxygen needs of a compromised myocardium and reduces the risk of complications. In addition, institute measures to avoid the hazards of immobility while encouraging rest.

Pain. Provide NTG, morphine, and supplemental oxygen as needed to eliminate or reduce chest pain. Ongoing evaluation and documentation of the effectiveness of the interventions are

NURSING CARE PLAN 34-1

Patient With Acute Coronary Syndrome

NURSING DIAGNOSIS **Decreased cardiac output** *related to* altered contractility and altered heart rate and rhythm *as evidenced by* decrease in BP, elevation in HR, dyspnea, dysrhythmias, diminished pulses, peripheral edema, and/or pulmonary edema

PATIENT GOAL Maintains stable signs of effective cardiac output

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Tissue Perfusion: Cardiac	***Cardiac Care: Acute***
• Angina _____ • Dysrhythmia _____ • Tachycardia _____ • Bradycardia _____ • Profuse diaphoresis _____ • Nausea _____ • Vomiting _____	• Monitor cardiac rhythm and rate and trends in blood pressure and hemodynamic parameters *to monitor for changes in cardiac output, blood pressure, and heart rhythm, which may lead to coronary hypoperfusion.* • Auscultate lungs for crackles or other adventitious sounds *that can indicate pulmonary edema.* • Monitor effectiveness of oxygen therapy (e.g., pulse oximetry) *to determine oxygenation of myocardial tissue and prevent further ischemia.* • Monitor serum cardiac markers (troponin, CK-MB levels) *to determine myocardial injury and recovery.* • Monitor neurologic, renal, and liver function *to evaluate blood perfusion to vital organs.*
Measurement Scale 1 = Severe 2 = Substantial 3 = Moderate 4 = Mild 5 = None	

NURSING DIAGNOSIS **Acute pain** *related to* an imbalance between myocardial oxygen supply and demand *as evidenced by* patient's report of severe chest pain and tightness with radiation of pain to the neck and arms, elevated cardiac markers, ECG changes supporting ST elevation MI

PATIENT GOAL Reports relief of pain

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Pain Control	***Cardiac Care***
• Uses preventive measures _____ • Uses analgesics appropriately _____ • Reports uncontrolled symptoms to health care professional _____ • Reports pain controlled _____	• Evaluate chest pain (e.g., PQRST [see Table 34-7]) *to accurately evaluate, treat, and prevent further ischemia.* • Monitor vital signs frequently *to determine baseline and ongoing changes.* • Obtain 12-lead ECG during pain episode *to help differentiate angina from extension of MI or pericarditis.*
Measurement Scale 1 = Never demonstrated 2 = Rarely demonstrated 3 = Sometimes demonstrated 4 = Often demonstrated 5 = Consistently demonstrated	***Pain Management*** • Provide the person optimal pain relief with prescribed analgesics *because pain exacerbates tachycardia and increases blood pressure.* • Consider the type and source of pain when selecting pain relief strategy *because angina responds to opioids and measures that increase myocardial perfusion.*

NURSING DIAGNOSIS **Anxiety** *related to* perceived or actual threat of death, pain, and/or possible lifestyle changes *as evidenced by* restlessness, agitation, and verbalization of concern over lifestyle changes and prognosis such as patient's statement, "What if I die? Everyone relies on me."

PATIENT GOAL Reports decreased anxiety and increased sense of self-control

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Anxiety Level	***Anxiety Reduction***
• Restlessness _____ • Verbalized apprehension _____ • Difficulty concentrating _____ • Distress _____	• Observe for verbal and nonverbal signs of anxiety *to identify signs of stress and intervene appropriately.* • Identify when level of anxiety changes, *since anxiety increases the need for oxygen.* • Use a calm, reassuring approach *to avoid increasing patient's anxiety.* • Instruct patient in use of relaxation techniques (e.g., relaxation breathing, imagery) *to enhance self-control.* • Encourage caregiver to stay with patient *to provide comfort and support.* • Encourage verbalization of feelings, perceptions, and fears *to decrease anxiety and stress.* • Provide factual information concerning diagnosis, treatment, and prognosis *to decrease fear of the unknown.*
Measurement Scale 1 = Severe 2 = Substantial 3 = Moderate 4 = Mild 5 = None	
Acceptance: Health Status	***Coping Enhancement***
• Recognizes reality of health situation _____ • Adjusts to change in health status _____ • Makes decisions about health _____	• Provide the patient with realistic choices about certain aspects of care *to support decision making.* • Assist the patient in identifying positive strategies *to deal with limitations and manage needed lifestyle or role changes.* • Help the patient to grieve and work through the losses of chronic illness.
Measurement Scale 1 = Never demonstrated 2 = Rarely demonstrated 3 = Sometimes demonstrated 4 = Often demonstrated 5 = Consistently demonstrated	

*Nursing diagnoses listed in order of priority.

Continued

NURSING CARE PLAN 34-1—cont'd

Patient With Acute Coronary Syndrome

NURSING DIAGNOSIS **Activity intolerance** *related to* general weakness secondary to decreased cardiac output and poor lung and tissue perfusion *as evidenced by* patient's report of fatigue with minimal activity, inability to care for self without dyspnea, and increased heart rate

PATIENT GOAL Achieves a realistic program of activity that balances physical activity with energy-conserving activities

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Activity Tolerance	***Cardiac Care***
• Oxygen saturation with activity _____ • Pulse rate with activity _____ • Ease of breathing with activity _____ • Walking pace _____ • Ease of performing ADLs _____	• Monitor patient's response to cardiac medications, *since these medications often affect BP and pulse.* • Arrange exercise and rest periods *to avoid fatigue and to increase activity tolerance without rapidly increasing cardiac workload.*
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	***Energy Management*** • Help patient understand energy conservation principles (e.g., the requirement for restricted activity) *to conserve energy and promote healing.* • Teach patient and caregiver techniques of self-care that will minimize oxygen consumption (e.g., self-monitoring and pacing techniques for performance of ADLs) *to promote independence and minimize O_2 consumption.*

NURSING DIAGNOSIS **Ineffective self-health management** *related to* lack of knowledge of disease process, risk factor reduction, rehabilitation, home activities, and medications *as evidenced by* frequent questioning about illness, management, and care after discharge

PATIENT GOAL Describes the disease process, measures to reduce risk factors, and rehabilitation activities necessary to manage the therapeutic regimen

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Knowledge: Cardiac Disease Management	***Cardiac Care: Rehabilitative***
• Usual course of disease process _____ • Signs and symptoms of worsening disease _____ • Strategies to reduce risk factors _____ • Importance of completing cardiac rehabilitation program _____ • Rationale for following a low-fat, low-cholesterol diet _____ • Importance of regular exercise _____	• Encourage realistic expectations for the patient and caregiver *to promote realistic decision making.* • Instruct the patient and caregiver on appropriate prescribed and over-the-counter medications *to promote compliance with medication regimens.* • Instruct the patient and caregiver on cardiac risk factor modification (e.g., smoking cessation, diet, exercise) *to increase patient's control of the illness.* • Instruct the patient on self-care of chest pain (e.g., take nitroglycerin; if chest pain unrelieved, seek emergency medical care). • Instruct the patient and caregiver on the exercise regimen, including warm-up, endurance, and cool-down, *to reduce cardiac risk factors.* • Instruct the patient and caregiver on wound care and precautions (e.g., sternal incision or catheterization site) *to prevent infection and promote healing after invasive therapies.* • Instruct the patient and caregiver on access to emergency services available in their community *to enable them to obtain immediate care if needed.*
Measurement Scale 1 = No knowledge 2 = Limited knowledge 3 = Moderate knowledge 4 = Substantial knowledge 5 = Extensive knowledge	

important. Once pain is relieved, you may have to deal with denial in a patient who interprets the absence of pain as an absence of cardiac disease.

Monitoring. Maintain continuous ECG monitoring while the patient is in the ED and intensive care unit and after transfer to a step-down or general unit. Dysrhythmias need to be identified quickly and treated. During the initial period after MI, ventricular fibrillation is the most common lethal dysrhythmia. In many patients, premature ventricular contractions or ventricular tachycardia precedes this dysrhythmia. Monitor the patient for reinfarction or ischemia by monitoring the ST segment for shifts above or below the baseline of the ECG. Silent ischemia can occur without clinical symptoms such as chest pain. Its presence places a patient at higher risk for adverse outcomes and even death. If you note ST segment changes, notify the physician. (See Chapter 36 for a complete discussion of ECG monitoring.)

Perform a physical assessment to detect deviations from the patient's baseline findings. Assess heart and breath sounds and any evidence of early HF (e.g., dyspnea, tachycardia, pulmonary congestion, distended neck veins). In addition to routine vital signs, monitor intake and output at least once a shift.

Assessment of the patient's oxygenation status is important, especially if the patient is receiving oxygen. If a nasal cannula is used to deliver oxygen, check the nares for irritation or dryness, which can cause considerable discomfort.

Rest and Comfort. It is important to promote rest and comfort with any degree of myocardial injury. Bed rest may be ordered for the first few days after an MI that involves a large portion of the ventricle. A patient with an uncomplicated MI (e.g., angina resolved, no signs of complications) may rest in a chair within 8 to 12 hours after the event. The use of a commode or bedpan is based on patient preference.

When sleeping or resting, the body requires less work from the heart than it does when active. It is important to plan nursing and therapeutic interventions to ensure adequate rest periods free from interruption. Comfort measures that can promote rest include a quiet environment, use of relaxation techniques (e.g., relaxation breathing, guided imagery), and assurance that staff are nearby and responsive to the patient's needs.

It is important that the patient understand the reasons why activity is limited but not completely restricted. Gradually increase the patient's cardiac workload through more demand-

TABLE 34-15 PHASES OF REHABILITATION AFTER ACUTE CORONARY SYNDROME

Phase I: Hospital
- Occurs while the patient is still hospitalized.
- Activity level depends on severity of angina or MI.
- Patient may initially sit up in bed or chair, perform range-of-motion exercises and self-care (e.g., washing, shaving), and progress to ambulation in hallway and limited stair climbing.
- Attention focuses on management of chest pain, anxiety, dysrhythmias, and complications.

Phase II: Early Recovery
- Begins after the patient is discharged.
- Usually lasts from 2-12 wk and is conducted in an outpatient facility.
- Activity level is gradually increased under the supervision of the cardiac rehabilitation team and with ECG monitoring.
- Team may suggest that physical activity (e.g., walking) be initiated at home.
- Information regarding risk factor reduction is provided at this time.

Phase III: Late Recovery
- Long-term maintenance program.
- Individual physical activity programs are designed and implemented at home, a local gym, or the rehabilitation center.
- Patient and caregiver possibly restructure lifestyles and roles.
- Therapeutic lifestyle changes should become lifelong habits.
- Medical supervision is still recommended.

ing physical tasks so that the patient can achieve a discharge activity level adequate for home care. Table 34-15 outlines the phases of cardiac rehabilitation.

Anxiety. Anxiety is present in all patients with ACS to some degree. Your role is to identify the source of anxiety and assist the patient in reducing it. If the patient is afraid of being alone, allow a caregiver to sit by quietly or check in with the patient frequently. If a source of anxiety is fear of the unknown, explore these concerns with the patient. For anxiety caused by lack of information, provide teaching based on the patient's stated need and level of understanding. Answer the patient's questions with clear, simple explanations.

It is important to start teaching at the patient's level rather than to present a prepackaged program. For example, patients generally are not ready to learn about the pathology of CAD. The earliest questions usually relate to how the disease affects perceived control and independence. Examples include the following.

- When will I leave the intensive care unit?
- When can I be out of bed?
- When will I be discharged?
- When can I return to work?
- How many changes will I have to make in my life?
- Will this happen again?

Tell the patient that a more complete teaching program will begin once the patient is feeling stronger. Frequently the patient may not be able to ask the most serious concern of ACS patients: Am I going to die? Even if a patient denies this concern, it is helpful for you to start a conversation by remarking that fear of dying is a common concern among most patients who have experienced ACS. This gives the patient "permission" to talk about an uncomfortable and fearful topic.

Emotional and Behavioral Reactions. Patients' emotional and behavioral reactions vary but frequently follow a predictable response pattern (Table 34-16). Your role is to understand what the patient is currently experiencing and to support the use of constructive coping styles. Denial may be a positive coping style in the early phase of recovery from ACS.

TABLE 34-16 PSYCHOSOCIAL RESPONSES TO ACUTE CORONARY SYNDROME

Denial
- May have history of ignoring signs and symptoms related to heart disease
- Minimizes severity of medical condition
- Ignores activity restrictions
- Avoids discussing illness or its significance

Anger and Hostility
- Is commonly expressed as, "Why did this happen to me?"
- May be directed at family, staff, or medical regimen

Anxiety and Fear
- Fears long-term disability and death
- Overtly manifests apprehension, restlessness, insomnia, tachycardia
- Less overtly manifests increased verbalization, projection of feelings to others, hypochondriasis
- Fears activity
- Fears recurrent chest pain, heart attacks, and sudden death

Dependency
- Is totally reliant on staff
- Is unwilling to perform tasks or activities unless approved by health care provider
- Wants to be monitored by ECG at all times
- Is hesitant to leave the intensive care or telemetry unit or hospital

Depression
- Mourns loss of health, altered body function, and changes in lifestyle
- Realizes seriousness of situation
- Begins to worry about future implications of health problem
- Shows manifestations of withdrawal, crying, apathy
- May be more evident after discharge

Realistic Acceptance
- Focuses on optimum rehabilitation
- Plans changes compatible with altered cardiac function
- Actively engages in lifestyle changes to address modifiable risk factors

Assess the support structure of the patient and caregiver. Help to determine how you can help maximize the support system. Often the patient is separated from the most significant support system at the time of hospitalization. Your role can include talking with the caregiver(s), informing them of the patient's progress, allowing the patient and the caregivers to interact as necessary, and supporting the caregivers who will provide the necessary support to the patient. Open visitation is helpful in decreasing anxiety and increasing support for the patient with ACS.[26] Social isolation has been associated with negative outcomes following MI in both men and women. It is important for you to help the patient identify additional support systems (e.g., spiritual care, Mended Hearts) that can assist after discharge.

CORONARY REVASCULARIZATION. Patients with ACS may undergo coronary revascularization with PCI or CABG surgery. The major nursing responsibilities for patient care after PCI involve monitoring for signs of recurrent angina; frequent

DELEGATION DECISIONS

Cardiac Catheterization and Percutaneous Coronary Intervention (PCI)

Role of Registered Nurse (RN)

Preprocedure

- Assess for allergies, especially to contrast medium. Perform baseline assessment, including vital signs, pulse oximetry, heart and breath sounds, neurovascular assessment of extremities (e.g., distal pulses, skin temperature, skin color, sensation).
- Teach patient and caregiver about procedure and postprocedure care.

Postprocedure

- Perform assessment and compare to baseline: vital signs, pulse oximetry, heart and breath sounds, neurovascular assessment of extremity used for procedure, assessment of catheter insertion site for hematoma or bleeding.
- Monitor ECG for dysrhythmias or other changes (e.g., ST segment elevation).
- Monitor patient for chest pain and other sources of pain or discomfort.
- Monitor IV infusions of anticoagulants, antiplatelets.
- Teach patient and caregiver about discharge medications (e.g., aspirin, prasugrel [Effient], antianginal medications).

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Administer medications before and after the procedure (consider state nurse practice act and agency policy).
- Assess neurovascular status of involved extremity every 15 min for the first hour, then according to agency policy (consider state nurse practice act and agency policy).
- Check for bleeding at catheter insertion site every 15 min for the first hour, then according to agency policy.
- Report changes in neurovascular status of involved extremity or any bleeding to the RN.

Role of Unlicensed Assistive Personnel (UAP)

- Take vital signs and report increases or decreases in heart rate or blood pressure to RN.
- Report decreases in pulse oximetry to the RN.
- Report patient complaints of chest pain, shortness of breath, and/or any other discomfort or distress to RN.
- Assist with oral hygiene, hydration, meals, and toileting.

assessment of vital signs, including HR and rhythm; evaluation of the catheter insertion site for signs of bleeding; neurovascular assessment of the involved extremity; and maintenance of bed rest per institution policy.

For patients having CABG surgery, care is provided in the intensive care unit for the first 24 to 36 hours. Ongoing and intensive monitoring of the patient's hemodynamic status is critical. The patient will have numerous invasive lines for monitoring cardiac status and other vital organs (see Chapter 66). These include (1) a pulmonary artery catheter for measuring CO and other hemodynamic parameters, (2) an intraarterial line for continuous BP monitoring, (3) pleural and mediastinal chest tubes for chest drainage, (4) continuous ECG monitoring to detect dysrhythmias, (5) an endotracheal tube connected to mechanical ventilation, (6) epicardial pacing wires for emergency pacing of the heart, (7) a urinary catheter to monitor urine output, and (8) a nasogastric tube for gastric decompression. Most patients are extubated within 6 hours and transferred to a step-down unit within 24 hours for continued monitoring of cardiac status.

Many of the postoperative complications that develop after CABG surgery relate to the use of CPB. Major consequences of CPB are systemic inflammation, which includes complications of bleeding and anemia from damage to red blood cells and platelets, fluid and electrolyte imbalances, hypothermia as blood is cooled as it passes through the CPB machine, and infections. Focus your nursing care on assessing the patient for bleeding (e.g., chest tube drainage, incision sites), hemodynamic monitoring, checking fluid status, replacing electrolytes as needed, and restoring temperature (e.g., warming blankets).

Postoperative dysrhythmias, specifically atrial dysrhythmias, are common in the first 3 days after CABG surgery. Postoperative atrial fibrillation (AF) occurs in 20% to 50% of patients.[24] β-Adrenergic blockers should be restarted as soon as possible after surgery (unless contraindicated) to reduce the incidence of AF. Discharge is often delayed in these patients in order to begin anticoagulation therapy. (See Chapter 36 for information on treatment of AF.)

Nursing care for the patient with a CABG also involves caring for the surgical sites (e.g., chest, arm, leg). Care of the radial artery harvest site includes monitoring sensory and motor function of the distal hand. The patient with radial artery harvest should take a calcium channel blocker for approximately 3 months to decrease the incidence of arterial spasm at the arm or anastomosis site.

Care of the leg incision is minimal since endoscopy is used to harvest the vein. Management of the chest wound, which involves a sternotomy, is similar to that of other chest surgeries (see Chapter 28). Chest incisions are usually closed with Dermabond and do not require dressings. Other interventions include strategies to manage pain and prevent venous thromboembolism (e.g., early ambulation, sequential compression device) and respiratory complications (e.g., use of incentive spirometer, splinting during coughing and deep-breathing exercises). (See Chapter 20 for care of the postoperative patient.)

Postoperatively, patients may experience some cognitive dysfunction. This includes impairment of memory, concentration, language comprehension, and social integration. Patients may cry or become teary. Postoperative cognitive dysfunction (POCD) can manifest days to weeks after surgery and may remain a permanent disorder. It is seen in 40% of patients several months after cardiac surgery.[27] (POCD is discussed in Chapter 20.)

In the older patient, elective CABG is generally well tolerated. However, the incidence of postoperative complications, including dysrhythmias, stroke, and infection, is high. Although the benefits of treatment may outweigh risks in this population, complications are higher than in younger individuals.

Postoperative nursing care of the patient with a MIDCAB or OPCAB procedure is similar to that for CABG surgery patients. Pain management is important regardless of the procedure. Patients report higher levels of pain with thoracotomy incisions than a sternotomy incision. The recovery time is somewhat shorter with these procedures, and patients often resume routine activities sooner than patients who have CABG surgery.

AMBULATORY AND HOME CARE. *Cardiac rehabilitation* is the restoration of a person to an optimal state of function in six areas: physiologic, psychologic, mental, spiritual, economic, and vocational. Many patients recover from ACS physically, but do not attain psychologic well-being. All patients (e.g., those with ACS, chronic stable angina, cardiac surgery) need to be referred to a cardiac rehabilitation program. In considering rehabilitation, the patient must recognize that CAD is a chronic disease. It is not curable, nor will it disappear by itself. Therefore

EVIDENCE-BASED PRACTICE

Translating Research into Practice

Do Exercise-Based Cardiac Rehabilitation Programs Improve Outcomes?

Clinical Question

In patients with coronary heart disease (P), do exercise-based cardiac rehabilitation programs (I) versus usual care (C) reduce mortality and morbidity and improve quality of life (O)?

Best Available Evidence

Systematic review of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- 47 RCTs (n = 10,794) of patients with myocardial infarction (MI), angina pectoris, coronary artery bypass graft (CABG), or percutaneous transluminal coronary angioplasty (PTCA). Exercise-based cardiac rehabilitation was exercise alone or with psychosocial or educational interventions. Usual care included standard medical care and drug therapy with no structured exercise training.
- Exercise-based rehabilitation reduced overall and cardiovascular mortality, decreased hospital admissions, and improved quality of life.
- Cardiac rehabilitation did not reduce risk of recurrent MI or revascularization (CABG or PTCA).

Conclusion

- Exercise-based cardiac rehabilitation reduces risk of dying from heart disease.

Implications for Nursing Practice

- Provide assistance in accessing cardiac rehabilitation programs.
- Reinforce benefits of adhering to recommended physical activity.
- Reduce program dropout rates by motivating patients to stay engaged.

Reference for Evidence

P, Patient population of interest; *I,* intervention or area of interest; *C,* comparison of interest or comparison group; *O,* outcomes of interest; *T,* timing (see p. 12).

EVIDENCE-BASED PRACTICE

Applying the Evidence

J.B. is 56-year-old white man who is being discharged from the hospital after having a myocardial infarction (MI) 4 days ago. You know that he is struggling with the lifestyle changes he must make, including how to kick his cigarette habit. While you are discussing the importance of smoking cessation with him, you share information from both the best available evidence and your clinical expertise. In addition, you describe a variety of smoking cessation interventions available for his consideration.

Best Available Evidence*	Clinician Expertise	Patient Preferences and Values
Combination strategies (e.g., medication plus behavioral support) work best to help patients to stop smoking.	You have heard from several patients who have successfully stopped smoking that they tried more than one intervention at a time to stop smoking (e.g., medication plus support group, hypnotherapy plus support group).	After reviewing all the information, J.B. informs you that he is willing to start with the nicotine patch but does not want to do anything else at this time.

Your Decision and Action

As his nurse, you respect and support his decision. You document your teaching and J.B.'s response. You notify his physician of his choice and request a prescription for the nicotine patch.

References for Evidence

Carpenter MJ, Hughes JR, Gray KM, et al: Nicotine therapy sampling to induce quit attempts among smokers unmotivated to quit: a randomized clinical trial, *Arch Intern Med* 171:1901, 2011.

basic changes in lifestyle must be made to promote recovery and future health. These changes often are needed when a person is middle aged or older. The patient must realize that recovery takes time. Resumption of physical activity after ACS or CABG surgery is slow and gradual. However, with appropriate and adequate supportive care, recovery is more likely to occur.

Patient Teaching. Patient teaching needs to occur at every stage of the patient's hospitalization and recovery (e.g., ED, telemetry unit, home care). The purpose of teaching is to give the patient and caregiver the tools they need to make informed decisions about their health. For teaching to be meaningful, the patient must be aware of the need to learn. Careful assessment of the patient's learning needs helps you set goals that are realistic (see Chapter 4).

The timing of the teaching is important. When patients and caregivers are in crisis (either physiologic or psychologic), they may not be interested in learning new information. Answer the patient's questions in simple, brief terms. The answers often require repetition. When the shock and disbelief accompanying a crisis subside, the patient and caregiver are better able to focus on new and more detailed information.

Limit your use of medical terminology. For example, explain that the heart, a four-chambered pump, is a muscle that needs oxygen, like all other muscles, to work properly. When blood vessels supplying the heart muscle with oxygen are blocked by plaque, less oxygen is available to the muscle. As a result, the heart cannot pump normally. It helps to have a model of the heart or to sketch a picture of what you are explaining. Literature written for a nonmedical audience is available through the AHA.

Anticipatory guidance involves preparing the patient and caregiver for what to expect in the course of recovery and rehabilitation. By learning what to expect during treatment and recovery, the patient gains a sense of control over his or her life.

The idea of perceived control is operationalized as the process by which the patient exercises choice and makes decisions by cutting back. Cutting back is one way of minimizing the psychologic and physiologic losses after MI (or any other life-changing event). For example, a middle-aged man who smokes two packs of cigarettes a day, is 20 pounds overweight, and gets no physical exercise has a seemingly overwhelming task. He may decide that he can live with a weight reduction plan and will get more exercise (although perhaps not daily) but that it is not possible for him to quit smoking. He reasons that because he is modifying two of the three risk factors, he will be healthier. Ideally, the tobacco risk factor should be a priority for this patient. If the information regarding risks and effects of tobacco use is not accepted, you must respect the patient's lifestyle choices.

TABLE 34-17 PATIENT & CAREGIVER TEACHING GUIDE

Acute Coronary Syndrome

Include the following information in the teaching plan for the patient with acute coronary syndrome and the caregiver.

- Signs and symptoms of angina and MI and what to do should they occur (e.g., take nitroglycerin)*
- When and how to seek help (e.g., contact EMS)
- Anatomy and physiology of the heart and coronary arteries
- Cause and effect of CAD
- Definition of terms (e.g., CAD, angina, MI, sudden cardiac death, heart failure)
- Identification of and plan to decrease risk factors* (see Tables 34-2, 34-3, and 34-4)
- Rationale for tests and treatments (e.g., ECG monitoring, blood tests, angiography), activity limitations and rest, diet, and medications*
- Appropriate expectations about recovery and rehabilitation (anticipatory guidance)
- Resumption of work, physical activity, sexual activity
- Measures to promote recovery and health
- Importance of the gradual, progressive resumption of activity*

*Identified by patients as most important to learn before discharge.

In addition to teaching the patient and caregiver what they wish to know, several types of information are essential in achieving optimal health. Table 34-17 presents a teaching guide for the patient with ACS.

Physical Activity. Physical activity, an integral part of rehabilitation, is necessary for optimal physiologic functioning and psychologic well-being. It has a direct, positive effect on maximal oxygen uptake, increasing CO, decreasing blood lipids, decreasing BP, increasing blood flow through the coronary arteries, increasing muscle mass and flexibility, improving the psychologic state, and assisting in weight loss and control. A regular schedule of physical activity, even after many years of sedentary living, is beneficial.[9]

One method of identifying levels of physical activity is through **metabolic equivalent (MET)** units: 1 MET is the amount of oxygen needed by the body at rest—3.5 mL of oxygen per kilogram per minute, or 1.4 cal/kg of body weight per minute. The MET determines the energy costs of various exercises (Table 34-18). Another method to determine levels of physical activity is the *Borg Rating of Perceived Exertion Scale.* This scale focuses on the patient's rating of the effort an activity requires (Table 34-19).

In the hospital the activity level is gradually increased so that by the time of discharge the patient can tolerate moderate-energy activities of 3 to 6 METs or rates activities 12 to 14 on the Borg scale. Many patients with UA that has resolved or an uncomplicated MI are in the hospital for approximately 3 or 4 days. By day 2, the patient can ambulate in the hallway and begin limited stair climbing (e.g., three or four steps). Many physicians order low-level exercise stress tests before discharge to assess readiness for discharge, optimal HR for an exercise program, and potential for ischemia or reinfarction. If tests are positive (i.e., ischemia at a low level of energy expenditure), the patient is evaluated for cardiac catheterization before discharge. If the test is negative, a catheterization may still be done before discharge or several weeks after discharge. Because of the short hospital stay, it is critical to give the patient specific guidelines for physical activity so that overexertion will not occur. It is

TABLE 34-18 ENERGY EXPENDITURE IN METABOLIC EQUIVALENTS

Low-Energy Activities (<3 METs or <3 cal/min)

Activities in Hospital
- Resting supine
- Eating
- Washing hands, face

Activities Outside Hospital
- Sweeping floor
- Painting, seated
- Driving a car
- Sewing by machine

Moderate-Energy Activities (3-6 METs or 3-5 cal/min)

Activities in Hospital
- Sitting on bedside commode
- Showering
- Using bedpan
- Walking at 3-4 mph

Activities Outside Hospital
- Ironing, standing
- Cycling at 5.5 mph on level ground
- Golfing
- General gardening
- Painting
- Ascending a flight of stairs

High-Energy Activities (6-8 METs or 6-8 cal/min)
- Walking 5 mph
- Performing carpentry
- Mowing lawn using walking mower

Very-High-Energy Activities (>9 METs or >9 cal/min)
- Cross-country skiing
- Running at >6 mph
- Cycling at >13 mph
- Shoveling heavy snow

TABLE 34-19 BORG RATING OF PERCEIVED EXERTION SCALE®*

Level of Exertion	RPE

Extremely hard	19
Maximal exertion	20

9 corresponds to very light exercise. For a healthy person, it is like walking slowly at his or her own pace for some minutes.
13 on the scale is somewhat hard exercise, but it still feels OK to continue.
17 (very hard) is strenuous exercise. A healthy person can still go on, but he or she really has to push himself or herself. It feels very hard, and the person is very tired.
19 on the scale is an extremely strenuous exercise level. For most people this is the most strenuous exercise they have ever experienced.

TABLE 34-20 PATIENT & CAREGIVER TEACHING GUIDE

FITT *Activity Guidelines After Acute Coronary Syndrome*

Include the following information in the teaching plan for the patient after an acute coronary syndrome:

Warm-up/Cool-down
Instruct the patient to perform mild stretching for 3-5 min before the physical activity and 5 min after the activity. Activity should not be started or stopped abruptly.

Frequency
Encourage the patient to perform physical activity on most days of the week.

Intensity
Activity intensity is determined by the patient's HR. If an exercise stress test has not been performed, the HR of the patient recovering from an MI should not exceed 20 beats/min over the resting HR.

Type of Physical Activity
Physical activity should be regular, rhythmic, and repetitive, using large muscles to build up endurance (e.g., walking, cycling, swimming, rowing).

Time
Physical activity sessions should be at least 30 min long. Instruct the patient to begin slowly at personal tolerance (perhaps only 5-10 min) and build up to 30 min.

important to tell the patient to "listen to what your body is saying"—the most important aspect of recovery.

Teach patients to check their pulse rate. The patient should know the limits within which to exercise. Tell the patient the maximum HR that should be present at any point. If the HR exceeds this level or does not return to the rate of the resting pulse within a few minutes, instruct the patient to stop and rest. Also instruct the patient to stop exercising and rest if chest pain or shortness of breath occurs.

In a normal, healthy person the minimum threshold for improving cardiopulmonary fitness is 60% of the age-predicted maximum HR (calculate by subtracting the person's age from 220). The ideal training target HR is 80% of maximum HR. The patient who has been physically inactive and is just beginning an exercise program should do so under supervision whenever possible.

The more important factor is the patient's response to physical activity in terms of symptoms rather than absolute HR, especially since many patients are taking β-adrenergic blockers and may not be able to reach a target HR. This point cannot be overstressed. Basic physical activity guidelines for patients after ACS follow the FITT formula (Table 34-20).

The basic categories of physical activity are isometric (static) and isotonic (dynamic). Most daily activities are a mixture of the two. *Isometric activities* involve the development of tension during muscular contraction but produce little or no change in muscle length or joint movement. Lifting, carrying, and pushing heavy objects are isometric activities. Because the HR and BP increase rapidly during isometric work, exercise programs involving isometric exercises should be limited.

Isotonic activities involve changes in muscle length and joint movement with rhythmic contractions at relatively low muscular tension. Walking, jogging, swimming, bicycling, and jumping rope are examples of activities that are predominantly isotonic. Isotonic exercise can put a safe, steady load on the heart and lungs and improve the circulation in many organs.

Discuss participation in an outpatient cardiac rehabilitation program with all patients (see Table 34-15). These programs are beneficial, but not all patients choose or are able to participate in them (e.g., location and travel limitations). Home-based cardiac rehabilitation programs can provide an alternative. Physical activity guidelines are developed for the patient, and staff maintains ongoing contact with the patient (e.g., telephone, exercise logs, Internet). Maintaining contact with the patient is one key to the success of these programs.

Older women (65 years or older) who experience MI may frequently have poor adherence to a regular physical activity program. Often these women describe continued fatigue post-MI that is poorly understood. Another factor that has been linked to poor adherence to a physical activity program after MI is depression. Depression is common among patients with CAD, especially in women.[28] Routinely screen for depression in all patients with CAD and recommend treatment as appropriate.

Resumption of Sexual Activity. It is important to include sexual counseling for cardiac patients and their partners. This often-neglected area of discussion may be difficult for both the patient and the health care provider to approach. However, the patient's concern about resumption of sexual activity after hospitalization for ACS often produces more stress than the physiologic act itself. Most of these patients change their sexual behavior not because of physical problems, but because they are concerned about sexual inadequacy, death during intercourse, and impotence. A concerned and knowledgeable health care provider could clarify any misconceptions with specific counseling.

Before providing guidelines on resumption of sexual activity, it is important to know the patient's physiologic status, the physiologic effects of sexual activity, and the psychologic effects of having a heart attack. Sexual activity for most middle-aged men and women with their usual partners is considered a moderate-energy activity equivalent to climbing two flights of stairs.[29]

You may be uncertain of how and when to begin counseling about resumption of sex. It is helpful to consider sex as a physical activity and to discuss or explore feelings in this area when other physical activities are discussed. One helpful approach is, "Many people who have had a heart attack wonder when they will be able to resume sexual activity. Has this been of concern to you?" You might also state, "Sexual activity is like other forms of activity and should be gradually resumed after MI. If your ability to perform sexually is concerning you, the energy you use is no more than walking briskly." Facilitate discussion by providing the patient with reading material on resumption of sexual activity. Say something like, "If resuming sexual activity has been of concern to you, this information should be helpful." This type of nonthreatening statement brings up the topic, allows the patient to explore personal feelings, and gives the patient an opportunity to raise questions with you or another health care provider.[28] Common guidelines are presented in Table 34-21.

The patient needs to know that the inability to perform sexually after MI is common and that sexual dysfunction usually disappears after several attempts. Reinforce the idea that

TABLE 34-21 PATIENT TEACHING GUIDE

Sexual Activity After Acute Coronary Syndrome

Include the following information in the teaching plan for the patient and his/her partner after an acute coronary syndrome:

- Sexual activity should be resumed at a level that corresponds to sexual activity before experiencing acute coronary syndrome.
- Physical training may improve the physiologic response to intercourse. Therefore daily physical activity during recovery should be encouraged.
- Consumption of food and alcohol should be reduced before intercourse is anticipated (e.g., waiting 3-4 hr after ingesting a large meal before engaging in sexual activity).
- Familiar surroundings and a familiar partner reduce anxiety.
- Masturbation may be a useful sexual outlet and may reassure the patient that sexual activity is still possible.
- Hot or cold showers should be avoided just before and after intercourse.
- Foreplay is desirable because it allows a gradual increase in heart rate before orgasm.
- Positions during intercourse are a matter of individual choice.
- Orogenital sex places no undue strain on the heart.
- A relaxed atmosphere free of fatigue and stress is optimal.
- Prophylactic use of nitrates to decrease chest pain during sexual activity may be recommended.
- Use of erectile agents (e.g., sildenafil [Viagra]) is contraindicated if taking nitrates in any form.
- Anal intercourse should be avoided because of the possibility of inducing a vasovagal response.

patience and understanding usually solve the problem. However, with the availability of drugs to correct erectile dysfunction, many male patients may be interested in using them. Caution the patient that these drugs are not to be used with nitrates because severe hypotension and even death have been reported.[15] Encourage patients to discuss the use of these drugs with their health care provider.

It is common for a patient who experiences chest pain on physical exertion to have some angina during sexual stimulation or intercourse. The patient may be instructed to take NTG prophylactically.[15] It is also helpful to have the patient avoid sex soon after a heavy meal or after excessive ingestion of alcohol, when extremely tired or stressed, or with unfamiliar partners. Patients should also avoid anal intercourse because of the likelihood of eliciting a vasovagal response.

Tell the patient that resumption of sex depends on the patient and his or her partner's emotional readiness and on the physician's assessment of the extent of recovery. It is generally safe to resume sexual activity 7 to 10 days after an uncomplicated MI.[29] However, some physicians believe that the patient should decide when he or she is ready to resume sex. Others believe that a patient must be asymptomatic when performing moderate-energy activities before resuming sexual activity.[29]

EVALUATION

Nursing Care Plan 34-1 presents the expected outcomes for the patient with an ACS.

SUDDEN CARDIAC DEATH

Sudden cardiac death (SCD) is unexpected death resulting from a variety of cardiac causes. An estimated 382,800 people experience SCD yearly.[1]

Etiology and Pathophysiology

In SCD a sudden disruption in cardiac function produces an abrupt loss of CO and cerebral blood flow. The affected person may or may not have a known history of heart disease. SCD is often the first sign of illness for 25% of those who die of heart disease.[30]

Acute ventricular dysrhythmias (e.g., ventricular tachycardia, ventricular fibrillation) cause the majority of cases of SCD. Structural heart disease accounts for 10% of the cases of SCD. Patients in this group include those with left ventricular hypertrophy, myocarditis, and hypertrophic cardiomyopathy. Hypertrophic cardiomyopathy is a risk factor for SCD, especially in young, athletic people.

Approximately 10% to 12% of cases of SCD among people less than age 45 occur in the absence of structural heart disease. These involve disturbances in the conduction system (e.g., prolonged QT syndrome, Wolff-Parkinson-White syndrome).

It is difficult to know who is at high risk for SCD. However, left ventricular dysfunction (EF less than 30%) and ventricular dysrhythmias following MI have been found to be the strongest predictors.[30] Other risk factors include history of syncope, left ventricular outflow tract obstruction (e.g., aortic stenosis), male gender (especially African American men), and family history of ventricular dysrhythmias.

Clinical Manifestations and Complications

Persons who experience SCD because of CAD fall into two groups: (1) those who did not have an acute MI and (2) those who did have an acute MI. The first group accounts for the majority of cases of SCD.[30] These victims usually have no warning signs or symptoms. Patients who survive are at risk for another SCD event because of the continued electrical instability of the heart that caused the initial event to occur.

The second, smaller group of patients includes those who have had an MI and have suffered SCD. Such patients usually have prodromal symptoms, such as chest pain, palpitations, and dyspnea. Death usually occurs within 1 hour of the onset of acute symptoms.

NURSING AND COLLABORATIVE MANAGEMENT SUDDEN CARDIAC DEATH

People who survive an episode of SCD require a diagnostic workup to determine whether they have had an MI. Thus serial analysis of cardiac markers and ECGs are done, and the patient is treated accordingly. (See section on collaborative care of ACS.) In addition, because most persons with SCD have CAD, cardiac catheterization is indicated to determine the possible location and extent of coronary artery occlusion. PCI or CABG surgery may be indicated.

Most SCD patients have a lethal ventricular dysrhythmia that is associated with a high incidence of recurrence. Thus it is useful to know when those persons are most likely to have a recurrence and what drug therapy is the most effective treatment. Assessment of dysrhythmias in these patients includes 24-hour Holter monitoring or other type of event recorder, exercise stress testing, signal-averaged ECG, and electrophysiology study (EPS).[30]

EPS is performed under fluoroscopy. Pacing electrodes are placed in selected intracardiac areas, and stimuli are selectively used to attempt to produce dysrhythmias. The patient's response to various antidysrhythmic medications is determined and monitored in a controlled environment. (Chapters 32 and 36 discuss EPS.)

The most common approach to preventing a recurrence is the use of an implantable cardioverter-defibrillator (ICD). It has been shown that an ICD improves survival compared with drug therapy alone.[30,31] (Chapter 36 discusses ICDs.) Drug therapy with amiodarone (Cordarone) may be used in conjunction with an ICD to decrease episodes of ventricular dysrhythmias.

Teaching people about the symptoms of impending cardiac arrest and the actions to take can save lives. Rapid cardiopulmonary resuscitation (CPR) (see Appendix A) and defibrillation with an automatic external defibrillator (AED), combined with early advanced cardiac life support, have greatly improved long-term survival rates for a witnessed arrest.

When caring for these patients, be alert to the patient's psychosocial adaptation to this sudden "brush with death." Many of these patients develop a "time bomb" mentality. They fear the recurrence of cardiac arrest and may become anxious, angry, and depressed. Their caregivers are likely to experience the same feelings. Patients and caregivers also may need to deal with additional issues such as possible driving restrictions, role reversal, and change in occupation. The grief response varies among patients and caregivers. Be attuned to the specific needs of the patient and caregiver and teach them accordingly while providing appropriate emotional support.

CASE STUDY

Myocardial Infarction

iStockphoto/Thinkstock

Patient Profile

D.M., a 51-year-old, white, successful executive, is rushed to the hospital by ambulance after experiencing crushing substernal chest pain that radiates down his left arm. He also complains of dizziness and nausea.

Subjective Data

- Has a history of chronic stable angina and hypertension
- States he is "borderline diabetic"
- Overweight but recently lost 10 pounds
- Rarely exercises
- Has three teenage children who are causing "problems"
- Recently experienced loss of best friend and business partner, who died from cancer

Objective Data

Physical Examination

- Diaphoretic, short of breath, nauseous
- BP 165/100 mm Hg, pulse rate 120/min, respiratory rate 26/min

Diagnostic Studies

- 12-lead ECG shows sinus tachycardia with ST elevation in leads II, III, aV_F, V_5, V_6 with occasional premature ventricular contractions
- Cardiac-specific troponin I level elevated
- Cholesterol 350 mg/dL (9.1 mmol/L)
- Hb A1C 9.0%
- Inferolateral wall MI

Collaborative Care

Emergency Department

- Oxygen 2 L/min via nasal cannula, titrate to keep O_2 saturation above 93%
- Continuous ECG monitoring
- Aspirin 325 mg (chewable)
- Eptifibatide (Integrilin) IV
- Weight-based heparin IV
- Nitroglycerin IV, titrate to relieve chest pain; hold for systolic BP below 100 mm Hg
- Morphine 2 to 4 mg IV q5min PRN for chest pain unrelieved by nitroglycerin
- Vital signs, pulse oximetry every 10 minutes
- Preparation of patient for transfer to cardiac catheterization laboratory for possible PCI

Discussion Questions

1. Which coronary artery(ies) is (are) most likely occluded in D.M.'s coronary circulation?
2. Explain the pathogenesis of CAD. What risk factors contribute to its development? What risk factors were present in D.M.'s life?
3. What is angina? How does chronic stable angina differ from angina associated with acute coronary syndrome?
4. Explain the pathophysiologic basis for the clinical manifestations that D.M. exhibited.
5. Explain the significance of the results of the laboratory tests and the 12-lead ECG findings.
6. Provide a rationale for each treatment measure ordered for D.M.
7. ***Priority Decision:*** Based on the assessment data presented, what are the priority nursing diagnoses? Identify any collaborative problems.
8. ***Priority Decision:*** What are the priority nursing interventions for D.M. immediately after his MI? Immediately after his PCI?
9. ***Delegation Decision:*** Identify activities that can be delegated to unlicensed assistive personnel (UAP).
10. ***Evidence-Based Practice:*** Two days after an uncomplicated PCI and the placement of two stents, D.M. wants to know what the most effective strategies are to prevent another MI. Based on his clinical situation, what would you tell him?

Evolve Answers and a corresponding concept map available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. In teaching a patient about coronary artery disease, the nurse explains that the changes that occur in this disorder include *(select all that apply)*
   - **a.** diffuse involvement of plaque formation in coronary veins.
   - **b.** abnormal levels of cholesterol, especially low-density lipoproteins.
   - **c.** accumulation of lipid and fibrous tissue within the coronary arteries.
   - **d.** development of angina due to a decreased blood supply to the heart muscle.
   - **e.** chronic vasoconstriction of coronary arteries leading to permanent vasospasm.
2. After teaching about ways to decrease risk factors for CAD, the nurse recognizes that additional instruction is needed when the patient says
   - **a.** "I would like to add weight lifting to my exercise program."
   - **b.** "I can only keep my blood pressure normal with medication."
   - **c.** "I can change my diet to decrease my intake of saturated fats."
   - **d.** "I will change my lifestyle to reduce activities that increase my stress."
3. A hospitalized patient with a history of chronic stable angina tells the nurse that she is having chest pain. The nurse bases his actions on the knowledge that ischemia
   - **a.** will always progress to myocardial infarction.
   - **b.** will be relieved by rest, nitroglycerin, or both.
   - **c.** indicates that irreversible myocardial damage is occurring.
   - **d.** is frequently associated with vomiting and extreme fatigue.
4. The nurse is caring for a patient who is 2 days post-MI. The patient reports that she is experiencing chest pain. She states, "It hurts when I take a deep breath." Which action would be a priority?
   - **a.** Notify the physician STAT and obtain a 12-lead ECG.
   - **b.** Obtain vital signs and auscultate for a pericardial friction rub.
   - **c.** Apply high-flow oxygen by face mask and auscultate breath sounds.
   - **d.** Medicate the patient with PRN analgesic and reevaluate in 30 minutes.
5. A patient is admitted to the ICU with a diagnosis of unstable angina. Which medication(s) would the nurse expect the patient to receive *(select all that apply)*?
   - **a.** ACE inhibitor
   - **b.** Antiplatelet therapy
   - **c.** Thrombolytic therapy
   - **d.** Prophylactic antibiotics
   - **e.** Intravenous nitroglycerin
6. A patient is recovering from an uncomplicated MI. Which rehabilitation guideline is a priority to include in the teaching plan?
   - **a.** Refrain from sexual activity for a minimum of 3 weeks.
   - **b.** Plan a diet program that aims for a 1- to 2-pound weight loss per week.
   - **c.** Begin an exercise program that aims for at least five 30-minute sessions per week.
   - **d.** Consider the use of erectile agents and prophylactic NTG before engaging in sexual activity.
7. The most common finding in individuals at risk for sudden cardiac death is
   - **a.** aortic valve disease.
   - **b.** mitral valve disease.
   - **c.** left ventricular dysfunction.
   - **d.** atherosclerotic heart disease.

1. b, c, d, 2. a, 3. b, 4. b, 5. a, b, e, 6. c, 7. c

LEARNING OUTCOMES

1. Compare the pathophysiology of systolic and diastolic ventricular failure.
2. Relate the compensatory mechanisms involved in heart failure (HF) to the development of acute decompensated heart failure (ADHF) and chronic HF.
3. Select appropriate nursing and collaborative interventions to manage the patient with ADHF.
4. Select appropriate nursing and collaborative interventions to manage the patient with chronic HF.
5. Describe the indications for cardiac transplantation and the nursing management of cardiac transplant recipients.

KEY TERMS

cardiac transplantation, p. 783
diastolic failure, p. 767
heart failure (HF), p. 766
paroxysmal nocturnal dyspnea (PND), p. 771
pulmonary edema, p. 770
systolic failure, p. 767

HEART FAILURE

Heart failure (HF) is an abnormal clinical syndrome that involves inadequate pumping and/or filling of the heart. It is a major health problem in the United States. This chapter discusses the management and nursing care of patients experiencing this syndrome.

HF causes the heart to be unable to provide sufficient blood to meet the oxygen needs of the tissues. In clinical practice, the terms *acute* and *chronic HF* have replaced the term *congestive HF* (CHF) because not all HF involves pulmonary congestion. However, the term *CHF* is still commonly used.[1,2]

HF is associated with numerous cardiovascular diseases, particularly long-standing hypertension, coronary artery disease (CAD), and myocardial infarction (MI). Unlike other cardiovascular diseases, HF is increasing in incidence and prevalence. This is due to improved survival after cardiac events and the growing aging population. Currently, about 5.1 million people in the United States have HF. The American Heart Association (AHA) estimates that over 600,000 new cases are diagnosed each year. HF is primarily a disease of older adults; approximately 10 in every 1000 persons over the age of 65 have HF. The incidence of HF is similar in men and women.[3]

HF is the most common reason for hospital admission in older adults. This places a significant economic burden on the health care system.[1] The complex, progressive nature of HF often results in poor outcomes, the most costly being hospital readmissions.[3]

Keller, RN, MSN, Instructor, Radford University School of Nursing: Clinical Simulation Center, Radford, Virginia.

CULTURAL & ETHNIC HEALTH DISPARITIES

Heart Failure

- African Americans have a higher incidence of HF, develop HF at an earlier age, and experience higher mortality rates related to HF than whites.
- African Americans may experience more ACE inhibitor–related angioedema than whites.
- Isosorbide dinitrate/hydralazine (BiDil) is used for the treatment of HF in African Americans. This co-packaged drug is approved for use only in this ethnic group.
- Asians have an extremely high risk (15%-50%) for ACE inhibitor–related cough.

ACE, Angiotensin-converting enzyme; *HF,* heart failure.

Etiology and Pathophysiology

Hypertension and CAD are the primary risk factors for HF. Most patients with HF have a history of hypertension. The risk of HF increases with the severity of hypertension. Other factors, such as diabetes, advanced age, tobacco use, obesity, and high serum cholesterol, also contribute to the development of HF.

HF may be caused by any interference with the normal mechanisms regulating cardiac output (CO). CO depends on (1) preload, (2) afterload, (3) myocardial contractility, and (4) heart rate (HR). (Preload and afterload are discussed in Chapter 32.) Any changes in these factors can lead to decreased ventricular function and HF.

The major causes of HF may be divided into two subgroups: (1) primary causes (Table 35-1) and (2) precipitating causes (Table 35-2). Precipitating causes often increase the workload of the ventricles, resulting in an acute condition and decreased heart function.

Genetic Link

Specific genes and gene mutations have been linked to the development of hypertension, CAD, and cardiomyopathy (weakening of the heart muscle) (see Chapters 33, 34, and 37). These cardiovascular diseases are known risk factors for HF. Knowledge of why some people with these diseases are at high risk for developing HF is incomplete. Future research into the effects of these gene mutations will most likely be related to the common causes of HF.[4]

Pathophysiology of Ventricular Failure. HF is classified as systolic or diastolic failure (or dysfunction). Patients can have isolated systolic or diastolic failure or a combination of both.

Systolic Failure. **Systolic failure** results from an inability of the heart to pump blood effectively. It is caused by impaired contractile function (e.g., MI), increased afterload (e.g., hypertension), cardiomyopathy, and mechanical abnormalities (e.g., valvular heart disease).

The left ventricle (LV) in systolic failure loses its ability to generate enough pressure to eject blood forward through the aorta. Over time, the LV becomes dilated and hypertrophied. The hallmark of systolic failure is a decrease in the left ventricular ejection fraction (EF). The EF is defined as the amount of blood ejected from the LV with each contraction. Normal EF is 55% to 60%. Patients with systolic HF generally have an EF less than 45%. It can be as low as 10%.

Diastolic Failure. **Diastolic failure** is the inability of the ventricles to relax and fill during diastole. Diastolic failure is often referred to as HF with normal EF. Decreased filling of the ventricles results in decreased stroke volume and CO. Diastolic failure is characterized by high filling pressures because of stiff ventricles. This results in venous engorgement in both the pulmonary and systemic vascular systems. Diastolic failure is usually the result of left ventricular hypertrophy from hypertension (most common), myocardial ischemia, valve disease (e.g., aortic, mitral), or cardiomyopathy. However, many patients do not have an identifiable heart disease. The diagnosis of diastolic failure is made based on the presence of HF symptoms with a normal EF.[5] Diastolic failure occurs more frequently in older adults, women, and people who are obese (see Gender Differences box).

Mixed Systolic and Diastolic Failure. Mixed systolic and diastolic failure is seen in disease states such as dilated cardiomyopathy (DCM). DCM is a condition in which poor systolic function is further compromised by dilated left ventricular walls that are unable to relax (see Chapter 37). These patients often have extremely low EFs (less than 35%), high pulmonary pressures, and *biventricular failure* (both ventricles are dilated and have poor filling and emptying capacity).

The patient with ventricular failure of any type may have low blood pressure (BP), low CO, and poor renal perfusion. Poor

TABLE 35-1 PRIMARY CAUSES OF HEART FAILURE

- Coronary artery disease, including myocardial infarction
- Hypertension, including hypertensive crisis
- Rheumatic heart disease
- Congenital heart defects (e.g., ventricular septal defect)
- Pulmonary hypertension
- Cardiomyopathy (e.g., viral, postpartum, substance abuse)
- Hyperthyroidism
- Valvular disorders (e.g., mitral stenosis)
- Myocarditis

TABLE 35-2 PRECIPITATING CAUSES OF HEART FAILURE*

Cause	Mechanism
Anemia	↓ O_2-carrying capacity of the blood stimulating ↑ in CO to meet tissue demands, leading to increase in cardiac workload and increase in size of LV
Infection	↑ O_2 demand of tissues, stimulating ↑ CO
Thyrotoxicosis	Changes the tissue metabolic rate, ↑ HR and workload of the heart
Hypothyroidism	Indirectly predisposes to ↑ atherosclerosis; severe hypothyroidism decreases myocardial contractility
Dysrhythmias	May ↓ CO and ↑ workload and O_2 requirements of myocardial tissue
Bacterial endocarditis	*Infection:* ↑ metabolic demands and O_2 requirements *Valvular dysfunction:* causes stenosis and regurgitation
Pulmonary embolism	↑ Pulmonary pressure resulting from obstruction leads to pulmonary hypertension, ↓ CO
Paget's disease	↑ Workload of the heart by ↑ vascular bed in the skeletal muscle
Nutritional deficiencies	May ↓ cardiac function by ↑ myocardial muscle mass and myocardial contractility
Hypervolemia	↑ Preload causing volume overload on the RV

*List is not all inclusive.
CO, Cardiac output; *LV,* left ventricle; *RV,* right ventricle.

GENDER DIFFERENCES

Heart Failure

Men	Women
• Men experience systolic failure more frequently than women. • Men with asymptomatic systolic failure experience greater mortality benefit from ACE inhibitor therapy than women.	• Women experience diastolic failure more frequently than men. • Women have a higher risk of ACE inhibitor–related cough than men. • Women experience more digitalis-related death than men. • Women with diabetes are more predisposed to heart failure than men.

ACE, Angiotensin-converting enzyme.

exercise tolerance and heart dysrhythmias are also common. Whether a patient arrives at this point acutely from an MI or chronically from worsening cardiomyopathy or hypertension, the body's response to this low CO is to mobilize its compensatory mechanisms to maintain CO and BP.

Compensatory Mechanisms. HF can have an abrupt onset as with acute MI, or it can be a subtle process resulting from slow, progressive changes. The overloaded heart uses compensatory mechanisms to try to maintain adequate CO. The main compensatory mechanisms include (1) sympathetic nervous system (SNS) activation, (2) neurohormonal responses, (3) ventricular dilation, and (4) ventricular hypertrophy.

Sympathetic Nervous System Activation. SNS activation is often the first mechanism triggered in low-CO states. However, it is the least effective compensatory mechanism. In response to an inadequate stroke volume and CO, SNS activation increases, resulting in the increased release of catecholamines (epinephrine and norepinephrine). This results in increased HR, increased myocardial contractility, and peripheral vasoconstriction. Initially, this increase in HR and contractility improves CO. However, over time these factors are harmful, since they increase the already failing heart's workload and need for oxygen. The vasoconstriction causes an immediate increase in preload, which may initially increase CO. However, an increase in venous return to the heart, which is already volume overloaded, actually worsens ventricular performance.

Neurohormonal Response. As the CO falls, blood flow to the kidneys decreases. This is sensed by the juxtaglomerular apparatus in the kidneys as decreased volume. In response, the kidneys release renin, which converts angiotensinogen to angiotensin I (see Chapter 45 and Fig. 45-4). Angiotensin I is subsequently converted to angiotensin II by a converting enzyme made in the lungs. Angiotensin II causes (1) the adrenal cortex to release aldosterone, which results in sodium and water retention; and (2) increased peripheral vasoconstriction, which increases BP. This response is known as the renin-angiotensin-aldosterone system (RAAS).

Low CO causes a decrease in cerebral perfusion pressure. In response, the posterior pituitary gland secretes antidiuretic hormone (ADH), also called vasopressin. ADH increases water reabsorption in the kidneys, causing water retention. As a result, blood volume is increased in a person who is already volume overloaded.

Other factors also contribute to the development of HF. The production of *endothelin*, a potent vasoconstrictor produced by the vascular endothelial cells, is stimulated by ADH, catecholamines, and angiotensin II. Endothelin results in further arterial vasoconstriction and an increase in cardiac contractility and hypertrophy.

Locally, proinflammatory cytokines are released by heart cells in response to various forms of cardiac injury (e.g., MI). Two cytokines, tumor necrosis factor (TNF) and interleukin-1 (IL-1), further depress heart function by causing hypertrophy, contractile dysfunction, and cell death. Over time, a systemic inflammatory response also occurs. This accounts for the cardiac and skeletal muscle myopathy and fatigue that accompany advanced HF.

Activation of the SNS and the neurohormonal response lead to elevated levels of norepinephrine, angiotensin II, aldosterone, ADH, endothelin, and proinflammatory cytokines. Together, these factors result in an increase in cardiac workload, myocardial dysfunction, and *ventricular remodeling.* Remodeling involves hypertrophy of the ventricular myocytes, resulting in large, abnormally shaped contractile cells. This altered geometric shape of the ventricles eventually leads to increased ventricular mass, increased wall tension, increased oxygen consumption, and impaired contractility. Although the ventricles become larger, they become less effective pumps. Ventricular remodeling is a risk factor for life-threatening dysrhythmias and sudden cardiac death (SCD).

Dilation. *Dilation* is an enlargement of the chambers of the heart (Fig. 35-1, *A*). It occurs when pressure in the heart chambers (usually the LV) is elevated over time. The heart muscle fibers stretch in response to the volume of blood in the heart at the end of diastole. The degree of stretch is directly related to the force of the contraction (systole) (this is the *Frank-Starling law*). This increased contraction initially leads to increased CO and maintenance of BP and perfusion. Dilation starts as an adaptive mechanism to cope with increasing blood volume. Eventually this mechanism becomes inadequate because the elastic elements of the muscle fibers are overstretched and can no longer contract effectively, thereby decreasing the CO.

Hypertrophy. *Hypertrophy* is an increase in the muscle mass and cardiac wall thickness in response to overwork and strain (Fig. 35-1, *B*). It occurs slowly because it takes time for this increased muscle tissue to develop. Initially, the increased contractile power of the muscle fibers leads to an increase in CO and maintenance of tissue perfusion. Over time, hypertrophic heart muscle has poor contractility, requires more oxygen to perform work, has poor coronary artery circulation (tissue becomes ischemic more easily), and is prone to dysrhythmias.

Counterregulatory Mechanisms. The body's attempts to maintain balance are demonstrated by several counterregulatory processes. Natriuretic peptides (atrial natriuretic peptide [ANP] and brain, or b-type, natriuretic peptide [BNP]) are hormones produced by the heart muscle. ANP is released from the atria and BNP is released from the ventricles in response to increased blood volume in the heart.[6]

The natriuretic peptides have renal, cardiovascular, and hormonal effects. Renal effects include (1) increased glomerular filtration rate and diuresis and (2) excretion of sodium (natriuresis). Cardiovascular effects include vasodilation and decreased BP. Hormonal effects include (1) inhibition of aldosterone and renin secretion and (2) interference with ADH release. The combined effects of ANP and BNP help to counter the adverse effects of the SNS and RAAS in patients with HF.[5]

Nitric oxide (NO) is another counterregulatory substance released from the vascular endothelium in response to the compensatory mechanisms activated in HF. Like the natriuretic

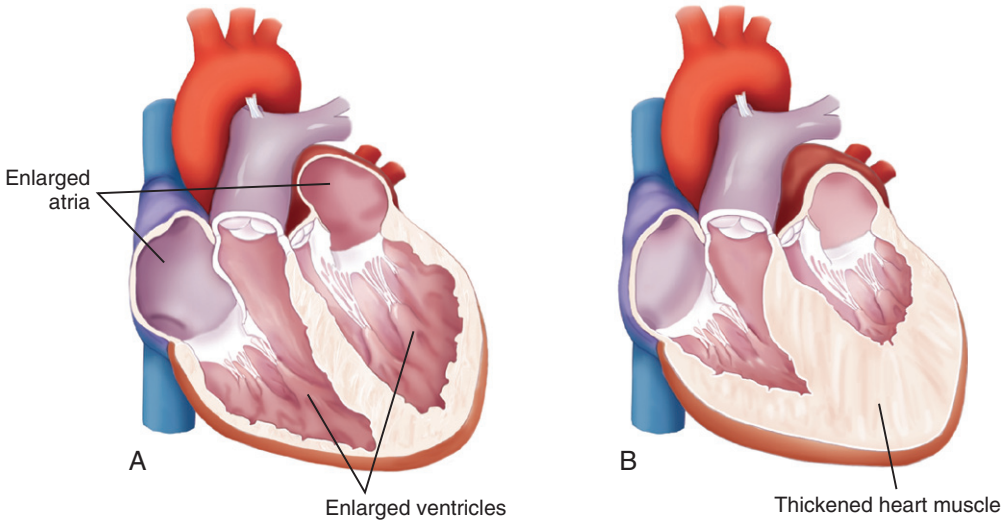

FIG. 35-1 **A,** Dilated heart chambers. **B,** Hypertrophied heart chambers.

peptides, NO works to relax the arterial smooth muscle, resulting in vasodilation and decreased afterload.

Cardiac compensation occurs when compensatory mechanisms succeed in maintaining an adequate CO that is needed for tissue perfusion. *Cardiac decompensation* occurs when these mechanisms can no longer maintain adequate CO and inadequate tissue perfusion results.

Types of Heart Failure

HF is usually manifested by biventricular failure, although one ventricle may precede the other in dysfunction. Normally the pumping actions of the left and right sides of the heart are synchronized, producing a continuous flow of blood. However, as a result of pathologic conditions, one side may fail while the other side continues to function normally for a time. Because of the prolonged strain, both sides of the heart eventually fail, resulting in biventricular failure (Fig. 35-2).

Left-Sided Heart Failure. The most common form of HF is left-sided HF. Left-sided HF results from left ventricular dysfunction. This prevents normal, forward blood flow and causes blood to back up into the left atrium and pulmonary veins. The increased pulmonary pressure causes fluid leakage from the pulmonary capillary bed into the interstitium and then the alveoli. This manifests as pulmonary congestion and edema.

Right-Sided Heart Failure. Right-sided HF occurs when the right ventricle (RV) fails to contract effectively. Right-sided HF causes a backup of blood into the right atrium and venous circulation. Venous congestion in the systemic circulation results in jugular venous distention, hepatomegaly, splenomegaly, vascular congestion of the gastrointestinal tract, and peripheral edema.

Right-sided HF may result from an acute condition such as right ventricular infarction or pulmonary embolism. *Cor pulmonale* (right ventricular dilation and hypertrophy caused by pulmonary disease) can also cause right-sided HF (see Chapters 28 and 29).

The primary cause of right-sided HF is left-sided HF. In this situation, left-sided HF results in pulmonary congestion and increased pressure in the blood vessels of the lung (pulmonary hypertension). Eventually, chronic pulmonary hypertension (increased right ventricular afterload) results in right-sided hypertrophy and HF.

Clinical Manifestations

Acute Decompensated Heart Failure

In acute decompensated HF (ADHF), an increase in the pulmonary venous pressure is caused by failure of the LV. This results in engorgement of the pulmonary vascular system (Fig. 35-3, *A* and *B*). As a result, the lungs become less compliant, and there is increased resistance in the small airways. In addition, the lymphatic system increases its flow to help maintain a constant volume of the pulmonary extravascular fluid. This early stage is clinically associated with a mild increase in the respiratory rate and a decrease in partial pressure of oxygen in arterial blood (PaO_2).

If pulmonary venous pressure continues to increase, the increase in intravascular pressure causes more fluid to move into the interstitial space than the lymphatics can remove. *Interstitial edema* occurs at this point (Fig. 35-3, *C*). Tachypnea develops, and the patient becomes symptomatic (e.g., short of breath). If the pulmonary venous pressure increases further, the alveoli lining cells are disrupted and a fluid containing red blood cells (RBCs) moves into the alveoli *(alveolar edema)*. As the disruption becomes worse from further increases in the pulmonary venous pressure, the alveoli and airways are flooded with fluid. This is accompanied by a worsening of the arterial blood gas values (i.e., lower PaO_2 and possible increased partial pressure of carbon dioxide in arterial blood [$PaCO_2$] and progressive respiratory acidemia).

ADHF can manifest as **pulmonary edema.** This is an acute, life-threatening situation in which the lung alveoli become filled with serosanguineous fluid (Fig. 35-3, *D*). The most common cause of pulmonary edema is left-sided HF secondary to CAD. (Other etiologic factors for pulmonary edema are listed in Table 28-25.)

Clinical manifestations of pulmonary edema are distinct. The patient is usually anxious, pale, and possibly cyanotic. The skin is clammy and cold from vasoconstriction caused by stimulation of the SNS. The patient has *dyspnea* (shortness of breath) and *orthopnea* (shortness of breath while lying down). Respiratory rate is often greater than 30 breaths/minute, and use of accessory muscles to breathe may be seen. There may be wheezing and coughing with the production of frothy, blood-tinged sputum. Auscultation of the lungs may reveal crackles, wheezes, and rhonchi throughout the lungs. The patient's HR is rapid,

PATHOPHYSIOLOGY MAP

and BP may be elevated or decreased depending on the severity of the HF.

Patients with ADHF can be categorized into one of four groups based on hemodynamic and clinical status: dry-warm, dry-cold, wet-warm, and wet-cold[1] (Table 35-3). The most common presentation is the warm and wet patient. This patient has adequate perfusion (warm) but has volume overload (e.g., congestion, dyspnea, edema).

TABLE 35-3 CLINICAL PROFILE IN ACUTE DECOMPENSATED HEART FAILURE

		Congestion (Wet)	
		No	**Yes**

Clinical Manifestations

Chronic Heart Failure

Chronic HF is characterized as a progressive worsening of ventricular function and chronic neurohormonal activation that results in ventricular remodeling. This process involves changes in the size, shape, and mechanical performance of the ventricle. The clinical manifestations of chronic HF depend on the patient's age, the underlying type and extent of heart disease, and which ventricle is failing to pump effectively. Table 35-4 lists the manifestations of right-sided and left-sided chronic HF. The patient with chronic HF usually has manifestations of biventricular failure. The Heart Failure Society of America (HFSA) developed the acronym FACES (*F*atigue, limitation of *A*ctivities, chest *C*ongestion/cough, *E*dema, and *S*hortness of breath) to help teach patients to identify HF symptoms[7] (see eTable 35-1 on the website for this chapter).

Fatigue. Fatigue is one of the earliest symptoms of chronic HF. The patient notes fatigue after usual activities and eventually limits these activities. The fatigue is caused by decreased CO, impaired perfusion to vital organs, decreased oxygenation of the tissues, and anemia. Anemia can result from poor nutrition, renal disease, or drug therapy (e.g., angiotensin-converting enzyme [ACE] inhibitors).

Dyspnea. Dyspnea is a common manifestation of chronic HF. It is caused by increased pulmonary pressures secondary to interstitial and alveolar edema. Dyspnea can occur with mild exertion or at rest. Orthopnea often accompanies dyspnea. Careful questioning of patients often reveals adaptive behaviors such as sleeping with two or more pillows or in a chair to aid breathing.

Paroxysmal nocturnal dyspnea (PND) occurs when the patient is asleep. It is caused by the reabsorption of fluid from dependent body areas when the patient is flat. The patient awakes in a panic, has feelings of suffocation, and has a strong desire to sit or stand up.

A cough is often associated with HF and may be the first clinical symptom. It begins as a dry, nonproductive cough and may be misdiagnosed as asthma or other lung disease. The

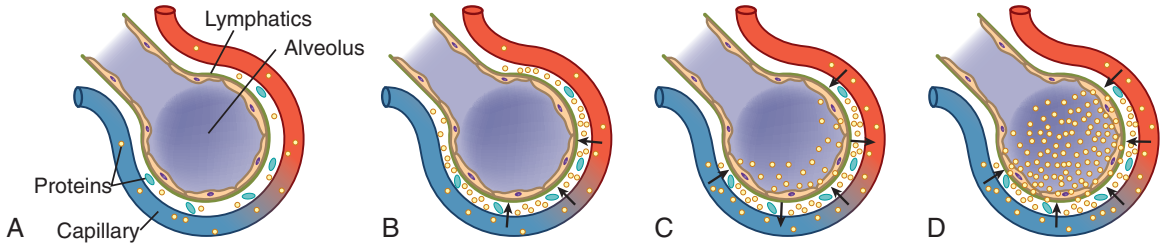

FIG. 35-3 As pulmonary edema progresses, it inhibits oxygen and carbon dioxide exchange at the alveolar-capillary interface. **A,** Normal relationship. **B,** Increased pulmonary capillary hydrostatic pressure causes fluid to move from the vascular space into the pulmonary interstitial space. **C,** Lymphatic flow increases in an attempt to pull fluid back into the vascular or lymphatic space. **D,** Failure of lymphatic flow and worsening of left-sided heart failure result in further movement of fluid into the interstitial space and into the alveoli.

TABLE 35-4 MANIFESTATIONS OF HEART FAILURE

Right-Sided Heart Failure	Left-Sided Heart Failure
Signs	
• RV heaves • Murmurs • Jugular venous distention • Edema (e.g., pedal, scrotum, sacrum) • Weight gain • ↑ HR • Ascites • Anasarca (massive generalized body edema) • Hepatomegaly (liver enlargement)	• LV heaves • Pulsus alternans (alternating pulses: strong, weak) • ↑ HR • PMI displaced inferiorly and posteriorly (LV hypertrophy) • ↓ PaO_2, slight ↑ $PaCO_2$ (poor O_2 exchange) • Crackles (pulmonary edema) • S_3 and S_4 heart sounds • Pleural effusion • Changes in mental status • Restlessness, confusion
Symptoms	
• Fatigue • Anxiety, depression • Dependent, bilateral edema • Right upper quadrant pain • Anorexia and GI bloating • Nausea	• Weakness, fatigue • Anxiety, depression • Dyspnea • Shallow respirations up to 32-40/min • Paroxysmal nocturnal dyspnea • Orthopnea (shortness of breath in recumbent position) • Dry, hacking cough • Nocturia • Frothy, pink-tinged sputum (advanced pulmonary edema)

cough is not relieved by position change or over-the-counter cough medicine.

Tachycardia. Tachycardia is an early clinical sign of HF. One of the body's first mechanisms to compensate for a failing ventricle is to increase the HR. Because of reduced CO, the SNS is activated, which increases HR. However, this response may be blocked or reduced in patients taking β-blocker medications.

Edema. Edema is a common sign of HF. It may occur in dependent body areas (peripheral edema), liver (hepatomegaly), abdominal cavity (ascites), and lungs (pulmonary edema and pleural effusion). If the patient is in bed, sacral and scrotal edema may develop. Pressing the edematous skin with the finger may leave a transient depression *(pitting edema).* The development of dependent edema or a sudden weight gain of more than 3 lb (1.4 kg) in 2 days is often a sign of ADHF. It is important to note that not all lower extremity edema is a result of HF. Hypoproteinemia, immobility, venous insufficiency, and certain medications can cause peripheral edema.

Nocturia. A person with chronic HF who has decreased CO will also have impaired renal perfusion and decreased urine output during the day. However, when the person lies down at night, fluid moves from the interstitial spaces back into the circulatory system. In addition, cardiac workload is decreased at night while resting. These combined effects result in increased renal blood flow and diuresis. The patient may complain of having to void frequently throughout the night.

Skin Changes. Because tissue capillary oxygen extraction is increased in a person with chronic HF, the skin may appear dusky. Often the lower extremities are shiny and swollen, with diminished or absent hair growth. Chronic swelling may result in pigment changes. This causes the skin to appear brown or brawny in areas covering the ankles and lower legs.

Behavioral Changes. Cerebral circulation may be reduced with chronic HF secondary to decreased CO. The patient or caregiver may report unusual behavior, including restlessness, confusion, and decreased attention span or memory. This may also be secondary to poor gas exchange and worsening HF. It is often seen in the late stages of HF.

Chest Pain. HF can precipitate chest pain (angina) because of decreased coronary artery perfusion from decreased CO and increased myocardial work. Chest pain may accompany either ADHF or chronic HF.

Weight Changes. Many factors contribute to weight changes. First, a progressive weight gain may occur because of fluid retention. Renal failure may also contribute to fluid retention. Abdominal fullness from ascites and hepatomegaly frequently causes anorexia and nausea. As HF advances, the patient may have cardiac *cachexia* with muscle wasting and fat loss. This can be masked by the patient's edematous condition and may not be seen until after the edema subsides.

Complications of Heart Failure

Pleural Effusion. *Pleural effusion* results from increasing pressure in the pleural capillaries. A transudation of fluid occurs from these capillaries into the pleural space. (Pleural effusion is discussed in Chapter 28.)

Dysrhythmias. Chronic HF causes enlargement of the chambers of the heart. This enlargement (stretching of the atrial and ventricular walls) can cause changes in the normal electrical pathways. When numerous sites in the atria fire spontaneously and rapidly (atrial fibrillation), the organized atrial depolarization (contraction) no longer occurs. Atrial fibrillation also promotes thrombus formation within the atria. Thrombi may break

loose and form emboli. This places patients with atrial fibrillation at risk for stroke. They require treatment with cardioversion, antidysrhythmics, and/or anticoagulants.

Patients with HF are also at risk for ventricular dysrhythmias (e.g., ventricular tachycardia [VT], ventricular fibrillation [VF]). VT and VF can lead to SCD. (SCD is discussed in Chapter 34, and dysrhythmias are discussed in Chapter 36.)

Left Ventricular Thrombus. With ADHF or chronic HF, the enlarged LV and decreased CO combine to increase the chance of thrombus formation in the LV. Once a thrombus has formed, it may also decrease left ventricular contractility, decrease CO, and worsen the patient's perfusion. The development of emboli from the thrombus also places the patient at risk for stroke.

Hepatomegaly. HF can lead to severe hepatomegaly, especially with RV failure. The liver becomes congested with venous blood. The hepatic congestion leads to impaired liver function. Eventually liver cells die, fibrosis occurs, and cirrhosis can develop (see Chapter 44).

Renal Failure. The decreased CO that accompanies chronic HF results in decreased perfusion to the kidneys and can lead to renal insufficiency or failure (see Chapter 47).

Classification of Heart Failure

In 1964 the New York Heart Association (NYHA) developed functional guidelines for classifying people with heart disease based on tolerance to physical activity. Because this system only reflected exercise capacity, the American College of Cardiology Foundation/AHA (ACCF/AHA) developed a staging system that identified disease progression and treatment strategies.[1] This system allows for identification of people at risk for developing HF but who do not currently have heart disease. The ACCF/AHA system encourages clinicians to actively address the patient's risk factors and treat any existing conditions to prevent further disease progression. This may help reduce the growing number of HF patients. The two systems are compared in Table 35-5.

Diagnostic Studies

Diagnosing HF is often difficult, since neither patient signs nor symptoms are highly specific, and both may mimic those associated with many other medical conditions (e.g., anemia, lung disease). Diagnostic tests for ADHF and chronic HF are presented in Table 35-6. A primary goal in diagnosis is to find the underlying cause of HF.

An endomyocardial biopsy (EMB) may be done in patients who develop unexplained, new-onset HF that is unresponsive to usual care.[8] EF is used to differentiate systolic and diastolic HF. This distinction is important to make in the early treatment of HF. EF is measured using echocardiography and/or nuclear imaging studies (see Table 32-6). Other useful diagnostic tests include electrocardiogram (ECG), chest x-ray, and heart catheterization.

Laboratory studies also aid in the diagnosis of HF. In general, BNP levels correlate positively with the degree of left ventricular failure. Many laboratories routinely measure the N-terminal prohormone of BNP (NT-proBNP). This is a more precise assay to aid in the diagnosis of HF (see Table 32-6). Levels are temporarily higher in patients receiving nesiritide (Natrecor) and may be high in patients with chronic, stable HF. Increases in BNP or NT-proBNP levels can be caused by conditions other than HF. These conditions include pulmonary embolism, renal failure, and acute coronary syndrome.

TABLE 35-5 NYHA FUNCTIONAL CLASSIFICATION OF HEART DISEASE AND ACCF/AHA STAGES OF HEART FAILURE

NYHA Functional Classification of Heart Disease	ACCF/AHA Stages of Heart Failure
Class I No limitation of physical activity. Ordinary physical activity does not cause fatigue, dyspnea, palpitations, or anginal pain.	**Stage A** Patients at high risk for HF (e.g., patients with hypertension, diabetes, metabolic syndrome) but without structural heart disease or symptoms of HF.
Class II Slight limitation of physical activity. No symptoms at rest. Ordinary physical activity results in fatigue, dyspnea, palpitations, or anginal pain.	**Stage B** Patients with structural heart disease (e.g., patients with history of MI, valve disease) but who have never shown signs or symptoms of HF.
Class III Marked limitation of physical activity but usually comfortable at rest. Less than ordinary physical activity causes fatigue, dyspnea, palpitations, or anginal pain.	**Stage C** Patients with prior or current symptoms of HF associated with known, underlying structural heart disease.
Class IV Inability to carry on any physical activity without discomfort. Symptoms of cardiac insufficiency or of angina may be present even at rest. If any physical activity is undertaken, discomfort is increased.	**Stage D** Patients with refractory HF (e.g., patients with severe symptoms at rest despite maximal medical therapy) who require specialized interventions.

Collaborative Care

Acute Decompensated Heart Failure

With the addition of new drugs and device therapies, the management of HF has dramatically changed in the past few years. Because of the large number of patients and the high cost of care related to hospital readmissions, strategies to improve outcomes have been developed. One example is the use of guideline-directed medical therapy as defined by the AACF/AHA.[1] Another example is specialized HF inpatient units with transitional programs to the outpatient setting to help manage these patients. These units are staffed with multidisciplinary HF teams, including nurses who are educated in the care of these patients. Table 35-6 lists the collaborative therapy for the patient with ADHF.

Patients with ADHF need continuous monitoring and assessment. This may be done in an intensive care unit (ICU) if the patient is unstable. In the ICU, you will monitor ECG and oxygen saturation continuously. Assess vital signs and urine output at least every hour. The patient may have hemodynamic monitoring, including intraarterial BP and pulmonary artery pressures (PAPs). If a pulmonary artery catheter is placed, eval-

TABLE 35-6 COLLABORATIVE CARE

Heart Failure

Both ADHF and Chronic HF	ADHF	Chronic HF
Diagnostic		
• History and physical examination • Determination of underlying cause • Serum chemistries, cardiac markers, BNP or NT-proBNP level (see Table 32-6), liver function tests, thyroid function tests, CBC, lipid profile, kidney function tests, urinalysis • Chest x-ray • 12-lead ECG • Hemodynamic monitoring • 2-dimensional echocardiogram • Nuclear imaging studies (see Table 32-6) • Cardiac catheterization	• Measurement of LV function • Endomyocardial biopsy	• Exercise stress testing
Collaborative Therapy		
• Treatment of underlying cause • Circulatory assist devices (e.g., ventricular assist device) • Daily weights • Sodium- and, possibly, fluid-restricted diet	• High Fowler's position • O_2 by mask or nasal cannula • BiPAP • Circulatory assist device: intraaortic balloon pump • Endotracheal intubation and mechanical ventilation • Vital signs, urine output at least q1hr • Continuous ECG and pulse oximetry monitoring • Hemodynamic monitoring (e.g., intraarterial BP, PAWP, CO) • Drug therapy (see Table 35-7) • Possible cardioversion (e.g., atrial fibrillation) • Ultrafiltration	• O_2 therapy at 2-6 L/min by nasal cannula if indicated • Rest-activity periods • Cardiac rehabilitation • Home health nursing care (e.g., telehealth monitoring) • Drug therapy (see Table 35-7) • Cardiac resynchronization therapy with biventricular pacing and internal cardioverter-defibrillator • LVAD • Cardiac transplantation • Palliative and end-of-life care

ADHF, Acute decompensated heart failure; *BiPAP,* bilevel positive airway pressure; *BNP,* b-type natriuretic peptide; *CO,* cardiac output; *HF,* heart failure; *LVAD,* left ventricular assist device; *NT-proBNP,* N-terminal prohormone of BNP; *PAWP,* pulmonary artery wedge pressure.

uate CO and pulmonary artery wedge pressure (PAWP). Therapy is titrated to maximize CO and reduce PAWP. A normal PAWP is generally between 8 and 12 mm Hg. Patients with ADHF may have a PAWP as high as 30 mm Hg. (Hemodynamic monitoring is discussed in Chapter 66.)

Supplemental oxygen helps increase the percentage of oxygen in inspired air. (Oxygen therapy is discussed in Chapter 29.) In severe pulmonary edema the patient may need noninvasive ventilatory support (e.g., bilevel positive airway pressure [BiPAP]) or intubation and mechanical ventilation. BiPAP is also effective in decreasing preload. (Ventilatory support is discussed in Chapter 66.)

Some patients with ADHF require hospitalization but are more stable. They are often admitted to a telemetry or stepdown unit for treatment. Assess these patients every 4 hours (e.g., vital signs, pulse oximetry) for adequate oxygenation. Record intake and output and daily weights to evaluate fluid status.

If the patient is dyspneic, place in a high Fowler's position with the feet horizontal in the bed or dangling at the bedside. This position helps decrease venous return because of the pooling of blood in the extremities. This position also increases the thoracic capacity, allowing for improved breathing.

Ultrafiltration (UF), or *aquapheresis,* is an option for the patient with volume overload.[9] It is a process to remove excess salt and water from the patient's blood. UF can rapidly remove intravascular fluid volume while maintaining hemodynamic stability. The ideal patients for UF are those with major pulmonary or systemic volume overload who have shown resistance to diuretics and are hemodynamically stable. UF also may be an appropriate adjunctive therapy for patients with HF and coexisting renal failure. (UF is discussed in Chapter 47.) Once the patient is more stable, determination of the cause of ADHF and pulmonary edema is important. Diagnosis of systolic or diastolic HF will then direct further management protocols.

Circulatory assist devices are used to manage patients with worsening HF. The intraaortic balloon pump (IABP) is a device that increases coronary blood flow to the heart muscle and decreases the heart's workload through a process called counterpulsation. It is useful in hemodynamically unstable patients because it decreases SVR, PAWP, and PAP, leading to improved CO. Ventricular assist devices (VADs) can be used to maintain the pumping action of a heart that cannot effectively contract by itself. A VAD is a battery-operated, mechanical pump that is surgically implanted. (IABPs and VADs are discussed in Chapter 66.)

Coexisting psychologic disorders, especially depression and anxiety, contribute to an increased risk of mortality and higher readmission rates and health care costs in patients with HF.[10] In addition, patients with psychologic disorders have poorer adherence to treatment and self-care.[11] Assess patients with HF for depression and anxiety and, if appropriate, initiate treatment plans.

Drug Therapy. Drug therapy is essential in treating ADHF (Table 35-7).

Diuretics. Diuretics are the mainstay of treatment in patients with volume overload. Diuretics act to decrease sodium reabsorption at various sites within the nephrons, thereby enhancing sodium and water loss. Decreasing intravascular volume with the use of diuretics reduces venous return (preload) and subsequently the volume returning to the LV. This allows the

TABLE 35-7 DRUG THERAPY

Heart Failure

Drug	Mechanism of Action
Diuretics (see Table 33-7)	
Loop Diuretics	• Decrease fluid volume • Decrease preload • Decrease pulmonary venous pressure • Relieve symptoms of heart failure (e.g., edema)
• furosemide (Lasix) • bumetanide (Bumex)	
Thiazide Diuretics*	
• hydrochlorothiazide (HCTZ) • metolazone (Zaroxolyn)	
Potassium-Sparing Diuretics	
• spironolactone (Aldactone) • eplerenone (Inspra)	
Renin-Angiotensin-Aldosterone System Inhibitors (see Table 33-7)	
ACE Inhibitors	• Dilate venules and arterioles • Improve renal blood flow • Decrease fluid volume • Relieve symptoms of heart failure
• captopril (Capoten) • benazepril (Lotensin) • enalapril (Vasotec)	
Angiotensin II Receptor Blockers	• Promote reverse remodeling • Decrease morbidity and mortality
• losartan (Cozaar) • valsartan (Diovan)	
Vasodilators	
• hydralazine (Apresoline)* • isosorbide dinitrate/ hydralazine (BiDil)* • nitrates (e.g., nitroglycerin [Nitro-Bid], isosorbide dinitrate [Isordil]) • nesiritide (Natrecor)† • nitroprusside (Nipride)†	• Reduce cardiac afterload, leading to increased CO • Dilate the arterioles of the kidneys, leading to increased renal perfusion and fluid loss • Decrease BP • Decrease preload • Relieve symptoms of heart failure (e.g., dyspnea)
β-Adrenergic Blockers* (see Table 33-7)	
• metoprolol (Toprol XL) • bisoprolol (Zebeta) • carvedilol (Coreg)	• Promote reverse remodeling • Decrease afterload • Inhibit SNS • Decrease morbidity and mortality
Positive Inotropes	
***β-Adrenergic Agonists**†* • dopamine (Intropin) • dobutamine (Dobutrex)	• Increase contractility (positive inotropic effect) • Increase CO • Increase heart rate (positive chronotropic effect)
***Phosphodiesterase Inhibitor**†* • milrinone (Primacor)	• Produce mild vasodilation • Increase stroke volume and CO
Digitalis Glycoside* • digoxin (Lanoxin)	• Promote vasodilation
Morphine†	• Decreases anxiety • Decreases preload and afterload
Antidysrhythmic Drugs (see Table 36-9)	• Prevent or treat dysrhythmias
Anticoagulants	• Prevent thromboembolism • Recommended for patients with an ejection fraction <20% and/or atrial fibrillation

*Used for chronic HF only.
†Used for ADHF only.
ACE, Angiotensin-converting enzyme; *ADHF,* acute decompensated heart failure; *CO,* cardiac output; *SNS,* sympathetic nervous system.

LV to contract more efficiently. CO is increased, pulmonary vascular pressures are decreased, and gas exchange is improved. Loop diuretics (e.g., furosemide [Lasix], bumetanide [Bumex]) can be administered by IV push and act rapidly in the kidneys.

Vasodilators. IV nitroglycerin is a vasodilator that reduces circulating blood volume. It also improves coronary artery circulation by dilating the coronary arteries. Therefore nitroglycerin reduces preload, slightly reduces afterload (in high doses), and increases myocardial oxygen supply. When titrating IV nitroglycerin, monitor BP frequently (every 5 to 10 minutes) to avoid symptomatic hypotension.

Sodium nitroprusside (Nipride) is a potent IV vasodilator that reduces both preload and afterload, thus improving myocardial contraction, increasing CO, and reducing pulmonary congestion.[12] Complications of IV sodium nitroprusside include (1) hypotension; and (2) thiocyanate toxicity, which can develop after 48 hours of use. Sodium nitroprusside is administered in an ICU, since symptomatic hypotension is the main adverse effect.

DRUG ALERT: Sodium Nitroprusside (Nipride)
- Assess BP before administration and continuously (every 5-10 min) during administration.
- Too rapid rate of IV administration can reduce BP too quickly.
- Headache, nausea, dizziness, dyspnea, blurred vision, sweating, and restlessness can occur.

Nesiritide, administered IV, is a recombinant form of BNP and causes both arterial and venous dilation. The main hemodynamic effects of nesiritide include (1) a reduction in PAWP and (2) a decrease in systemic BP. Although classified as a vasodilator, nesiritide is also a neurohormonal blocking agent. It can be used for short-term treatment of ADHF.[1,13] Nesiritide does not require titration after the initial IV bolus. It can be given in the emergency department (ED) and non-ICU setting. Because the main adverse effect of nesiritide is symptomatic hypotension, monitor BP closely.

Morphine. Morphine sulfate reduces preload and afterload. It is frequently used in the treatment of acute coronary syndrome and HF. It dilates both the pulmonary and systemic blood vessels. Results include a decrease in pulmonary pressures and myocardial oxygen needs, and an improvement in gas exchange. When morphine is used, the patient often experiences relief from dyspnea and, consequently, the anxiety that often is associated with dyspnea.

Use morphine cautiously in patients with ADHF. Morphine is related to more adverse events, including a greater need for mechanical ventilation, more ICU admissions, prolonged hospitalization, and higher mortality rates.[14]

Positive Inotropes. Inotropic therapy increases myocardial contractility. Drugs include β-adrenergic agonists (e.g., dopamine [Intropin], dobutamine [Dobutrex], epinephrine, norepinephrine [Levophed]), the phosphodiesterase inhibitor milrinone (Primacor), and digitalis. The β-adrenergic agonists are only used as a short-term treatment of ADHF. In addition to increasing myocardial contractility and SVR, dopamine dilates the renal blood vessels and enhances urine output. Unlike dopamine, dobutamine is a selective β-adrenergic agonist and works primarily on the β_1-receptors in the heart. Dobutamine does not increase SVR and is preferred for short-term treatment of ADHF.[15]

DRUG ALERT: Dopamine (Intropin)
- Monitor IV site for signs of extravasation.
- Tissue necrosis with sloughing can occur with drug extravasation.
- High dosages may produce ventricular dysrhythmias.

Milrinone is a phosphodiesterase inhibitor that has been called an inodilator. It increases myocardial contractility (inotropic effect) and promotes peripheral vasodilation. Inhibition of phosphodiesterase increases cyclic adenosine monophosphate (cAMP). This enhances calcium entry into the cell and improves myocardial contractility. Milrinone increases CO and reduces BP (decrease afterload). Like dopamine and dobutamine, this drug is available only for IV use. Adverse effects include dysrhythmias, thrombocytopenia, and hepatotoxicity.

Digitalis is a positive inotrope that improves left ventricular function. Digitalis increases contractility but also increases myocardial oxygen consumption. Because digitalis requires a loading dose and time to work, it is not recommended for the initial treatment of ADHF.[15]

Currently, inotropic therapy is only recommended for use in the short-term management of patients with ADHF who have not responded to conventional pharmacotherapy (e.g., diuretics, vasodilators, morphine).[1]

Collaborative Care
Chronic Heart Failure

The main goals in the treatment of chronic HF are to treat the underlying cause and contributing factors, maximize CO, reduce symptoms, improve ventricular function, improve quality of life, preserve target organ function, and improve mortality and morbidity risks (see Table 35-6). The management of hypertension is discussed in Chapter 33, CAD in Chapter 34, dysrhythmias in Chapter 36, and valvular disorders in Chapter 37.

In a person with HF, oxygen saturation of the blood can be reduced because the blood is not adequately oxygenated in the lungs. Administration of oxygen improves saturation and assists in meeting tissue oxygen needs. This helps to relieve dyspnea and fatigue. Optimally pulse oximetry is used to monitor the need for and effectiveness of oxygen therapy.

Physical and emotional rest allows the patient to conserve energy and decreases the need for additional oxygen. The degree of rest recommended depends on the severity of HF. A patient with severe HF may be on bed rest with limited activity. A patient with mild to moderate HF can be ambulatory with restriction of strenuous activity. Instruct the patient to participate in prescribed activities with adequate recovery periods. A structured exercise program, such as cardiac rehabilitation, should be offered to all patients with chronic HF.

Nonpharmacologic therapies are an integral part of the care of HF patients. One therapy is *biventricular pacing* or *cardiac resynchronization therapy* (CRT). Traditional pacemakers pace one or two chambers (e.g., right atrium and/or right ventricle). In HF, neurohormonal effects and cardiac remodeling can result in dyssynchrony of the ventricular contractions. This contributes to poor CO. In CRT an extra pacing lead is placed through the coronary sinus to a coronary vein of the LV. This lead coordinates right and left ventricular contractions through biventricular pacing (Fig. 35-4). The ability to have normal electrical conduction (synchrony) between the RV and the LV increases left ventricular function and CO.

Life-threatening ventricular dysrhythmias (e.g., VT) can cause SCD. The addition of an implantable cardioverter-defibrillator (ICD) with CRT is often warranted. (Pacemakers and defibrillators are discussed in Chapter 36.)

Several mechanical options are available to sustain HF patients with deteriorating conditions, especially those awaiting cardiac transplantation. These include the IABP and VADs.

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

Can Exercise Help Depression in Heart Failure Patients?

Clinical Question

For patients with heart failure (P), what is the effect of aerobic exercise (I) versus usual care (C) on depressive symptoms (O) at 3 and 12 mo (T)?

Best Available Evidence

Randomized controlled trial (RCT)

Critical Appraisal and Synthesis of Evidence

RCT of 82 medical centers (n = 2322) of patients with stable chronic heart failure.

- Intervention was aerobic exercise with a goal of 90 min/wk for months 1-3 followed by home exercise for ≥120 min/wk for months 4-12. Usual care was education and guideline-based heart failure care.
- Outcome measure was depressive symptoms.
- Patients engaged in aerobic exercise had fewer depressive symptoms at 3 and 12 months compared with patients receiving usual care.

Conclusion

- Exercise resulted in a significant decrease in depressive symptoms.

Implications for Nursing Practice

- Encourage patients with heart failure to discuss with their health care provider reasonable exercise goals.
- Emphasize the mental and physical benefits to patients of engaging in supervised regular aerobic exercise.

Reference for Evidence

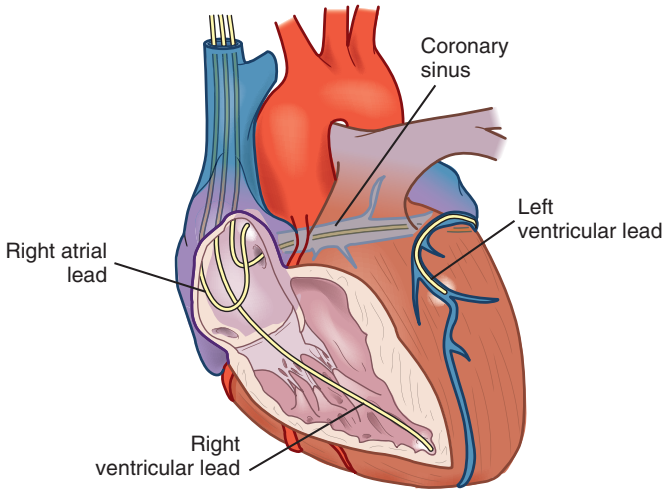

FIG. 35-4 Placement of pacing leads in cardiac resynchronization therapy.

However, the limitations of bed rest and the risk of infection and vascular complications preclude long-term use of IABP. VADs provide highly effective long-term support and have become standard care in many heart transplant centers. VADs are used as a bridge to transplantation. They effectively increase heart function until a donor heart becomes available. The use of a permanent, implantable VAD, known as *destination therapy*,

EVIDENCE-BASED PRACTICE

Applying the Evidence

T.F. is a 62-year-old female patient recovering from an episode of acute decompensated heart failure (ADHF). Her HF is Class III in the New York Heart Association Functional Classification of Heart Disease (see Table 35-5). Her physician has recommended biventricular pacing (cardiac resynchronization therapy) for treatment of her HF symptoms. She tells you that she does not want any artificial implants, and that she has researched the use of hawthorn for treatment of her heart disease.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Strong evidence supports the use of biventricular pacing (cardiac resynchronization therapy) to improve symptoms, exercise capacity, quality of life, ejection fraction, and survival and to decrease hospitalizations in patients like T.F.	You know the benefits of and possible complications related to biventricular pacing in patients with T.F.'s situation. You also know that there is strong evidence supporting the use of hawthorn in patients with mild to moderate HF (see Complementary & Alternative Therapies box on p. 777).	Patient does not want any artificial implants. She wants to consider alternative (herbal) therapy.

Your Decision and Action

You review the risks and benefits of biventricular pacing and herbal (hawthorn) therapy for the treatment of HF with T.F. She remains committed to the use of hawthorn—at least for a trial period. You support her decision and inform the physician of her wishes.

Reference for Evidence

Yancy CW, Jessup M, Bozkurt B, et al: 2013 ACCF/AHA guideline for the management of heart failure: executive summary, *Circulation* 128:e1, 2013.

is an option for some HF patients with advanced NYHA Functional Class IV HF who are not candidates for heart transplantation. (IABPs and VADs are discussed in Chapter 66.)

Drug Therapy. Drug therapy for chronic HF is presented in Table 35-7.

Diuretics. Diuretics are used to reduce edema, pulmonary venous pressure, and preload (see Table 33-7). If excess extracellular fluid is removed, blood volume returning to the heart can be reduced and cardiac function improved.

Diuretics act on the kidney by promoting excretion of sodium and water. Many varieties of diuretics are available. Loop diuretics (e.g., furosemide, bumetanide) are potent diuretics. These drugs act on the ascending loop of Henle to promote sodium, chloride, and water excretion. Problems in using loop diuretics include reduction in serum potassium levels, ototoxicity, and possible allergic reaction in patients sensitive to sulfa-type drugs.

Thiazide diuretics inhibit sodium reabsorption in the distal tubule, thus promoting excretion of sodium and water. They can be added to loop diuretics to obtain results if patients become resistant to loop diuretics. Thiazide diuretics also can cause severe reductions in potassium levels.

Diuretics are effective in relieving the congestive symptoms of HF. However, their use does activate the SNS and RAAS, which can exacerbate the HF syndrome. In chronic HF the lowest effective dose of diuretic should be used.

Renin-Angiotensin-Aldosterone System Inhibitors

Angiotensin-Converting Enzyme Inhibitors. ACE inhibitors are the primary drug of choice for blocking the RAAS system in HF patients with systolic failure.[1,16,17] Examples of ACE inhibitors are listed in Table 35-7. Other examples of ACE inhibitors are discussed in Chapter 33 and listed in Table 33-7.

The conversion of angiotensin I to the potent vasoconstrictor angiotensin II requires ACE (see Chapter 45, Fig. 45-4). ACE inhibitors act by blocking this enzyme, resulting in reduced levels of angiotensin II. As a result, plasma aldosterone levels are also reduced. Thus ACE inhibitors serve as neurohormonal blocking agents. Consequently, ACE inhibitors also decrease the development of ventricular remodeling by inhibiting ventricular hypertrophy.

Because CO is dependent on afterload in chronic HF, the reduction in SVR seen with the use of ACE inhibitors causes a significant increase in CO. Although the use of ACE inhibitors may decrease BP, tissue perfusion is maintained or increased as a result of improved CO. In addition, diuresis is enhanced by the suppression of aldosterone.

DRUG ALERT: Captopril (Capoten)

- Excessive hypotension and hyperkalemia may occur.
- Monitor patient for first-dose hypotension (first-dose syncope).
- Skipping doses or discontinuing the drug can result in rebound hypertension.
- Angioedema, a rare adverse effect, can develop suddenly and can be life threatening.

Major side effects of ACE inhibitors include symptomatic hypotension, intractable cough, hyperkalemia, *angioedema* (allergic reaction involving edema of the face and airways), and renal insufficiency (when ACE inhibitors are used in high doses). Aging and baseline renal insufficiency slow the metabolism of ACE inhibitors and may lead to increased serum drug levels. Carefully monitor patients taking ACE inhibitors for potential adverse effects. For example, a cough may be attributed to ACE inhibitors when, in fact, it is also a common symptom of an exacerbation of HF. It is critical that the exact cause of cough and other side effects be confirmed before stopping ACE inhibitor therapy.

Angiotensin II Receptor Blockers. For patients who are unable to tolerate ACE inhibitors, angiotensin II receptor blockers (ARBs) (see Table 33-7) are recommended.[18,19] These agents prevent the vasoconstrictor and aldosterone-secreting effects of angiotensin II by binding to the angiotensin II receptor sites.

Aldosterone Antagonists. Spironolactone (Aldactone) and eplerenone (Inspra) are aldosterone antagonists. They block the harmful neurohormonal effects of aldosterone on the heart blood vessels. They are also potassium-sparing diuretics that promote sodium and water excretion while retaining potassium. These effects occur because these agents bind to receptors at the aldosterone-dependent sodium-potassium exchange site in the distal renal tube.

DRUG ALERT: Spironolactone (Aldactone)

- Monitor potassium levels during treatment.
- Use with caution in patients taking digoxin, since hyperkalemia may reduce the effects of digoxin.
- Instruct patient to avoid foods high in potassium (e.g., bananas, oranges, dried apricots).
- Assess male patients for gynecomastia, a common side effect of long-term use of spironolactone.

β-Adrenergic Blockers. β-Adrenergic blockers directly block the negative effects of the SNS (e.g., increased HR) on the failing

COMPLEMENTARY & ALTERNATIVE THERAPIES

Hawthorn

Scientific Evidence*

- Strong evidence for its use in mild to moderate heart failure
- May inhibit angiotensin-converting enzyme
- May have a diuretic effect
- May reduce incidence of sudden cardiac death in patients with ejection fraction >25%

Nursing Implications

- May add to the effects of cardiac glycosides, antihypertensives, and cholesterol-lowering drugs
- Potentially beneficial treatment for patients who cannot or will not take prescription drugs and may offer additive benefits to established therapies

*Based on a systematic review of scientific literature. Retrieved from *www.naturalstandard.com*.

heart. They can also help in reducing the effect of renin.[19] Because β-blockers can reduce myocardial contractility, care must be taken to start slowly. Dosage is increased every 2 weeks as tolerated by the patient. Major adverse effects include edema, worsening of HF, hypotension, fatigue, and bradycardia. Three β-blockers are approved for use in HF patients: carvedilol (Coreg), bisoprolol (Zebeta), and metoprolol CR/XL (Toprol XL).[1,18]

DRUG ALERT: Carvedilol (Coreg)

- Overdosage can produce profound bradycardia, hypotension, bronchospasm, and cardiogenic shock.
- Obtain standing BP 1 hr after dosing to assess tolerance.
- Abrupt withdrawal may result in sweating, palpitations, and headaches.

Vasodilators

Nitrates. Nitrates cause vasodilation by acting directly on the smooth muscle of the vessel wall. Nitrates can be used in combination with hydralazine (Apresoline) for chronic HF management in patients who cannot tolerate ACE inhibitors or ARBs. Nitrates are of particular benefit in the management of myocardial ischemia related to HF because they promote vasodilation of the coronary arteries.

One specific problem with the use of nitrates in HF is nitrate tolerance. In addition, men with HF may experience erectile dysfunction and as a result take an erectile agent (e.g., sildenafil [Viagra]). Erectile agents are contraindicated in patients taking nitrates, since together they produce symptomatic hypotension.

BiDil. A combination drug containing isosorbide dinitrate and hydralazine (BiDil) is used for the treatment of HF in African Americans who are already being treated with standard therapy. The drug is only approved for use with this ethnic group.[20] How these two drugs work together is not fully known. As an antihypertensive agent, hydralazine relaxes the arteries and decreases the work of the heart. The antianginal agent isosorbide dinitrate relaxes the veins as well as the arteries. Isosorbide seems to work by releasing nitric oxide at the blood vessel wall, but its effect usually wears off after half a day. Hydralazine may prevent this loss of effect. Common side effects of isosorbide/hydralazine are headache and dizziness.

Positive Inotropes. Digitalis preparations (e.g., digoxin [Lanoxin]) increase the force of cardiac contraction *(inotropic action)*. They also decrease the HR *(chronotropic action)*. These actions allow for more complete emptying of the ventricles, reducing the volume remaining in the ventricles during diastole. CO increases due to the increased stroke volume from improved contractility.[19]

Patients taking a digitalis preparation are at risk for digitalis toxicity. Hypokalemia, secondary to the use of potassium-depleting diuretics (e.g., thiazides, loop diuretics), is one of the most common causes of digitalis toxicity. Low serum potassium enhances the action of digitalis, causing a therapeutic dose to reach toxic levels. Similarly, hyperkalemia inhibits the action of digitalis, resulting in a subtherapeutic dose. Both hypokalemia and hyperkalemia also cause dysrhythmias. Monitor serum potassium levels of all patients taking digitalis preparations and potassium-depleting and potassium-sparing diuretics. Other electrolyte imbalances, such as hypercalcemia and hypomagnesemia, can also precipitate digitalis toxicity. (Manifestations of electrolyte imbalances are discussed in Chapter 17.)

DRUG ALERT: Digoxin (Lanoxin)

- Monitor for signs of hypokalemia and hyperkalemia, since these can increase or decrease the effects of digoxin, respectively.
- Monitor for early signs of toxicity: anorexia, nausea and vomiting, fatigue, headache, depression, visual changes.
- Monitor for late signs of toxicity: dysrhythmias (e.g., bradycardia, atrioventricular block).

Diseases of the kidney and liver increase the risk of digitalis toxicity because most preparations are metabolized and eliminated by these organs. An older adult is especially prone to digitalis toxicity. This is because digitalis accumulation occurs sooner with decreased liver and kidney function and slowed body metabolism.

The usual treatment of toxicity consists of withholding the drug until the symptoms subside. In the case of life-threatening toxicity, IV digoxin immune Fab (ovine) (Digibind) is an antidote. The treatment of life-threatening dysrhythmias is instituted as needed (see Chapter 36).

Nutritional Therapy

Poor adherence to a low-sodium diet and failure to take prescribed medications as directed are the two most common reasons for readmissions of HF patients to the hospital.[21] Therefore it is critical that you accurately assess a patient's diet.

Diet teaching and weight management are essential to the patient's control of chronic HF. You or a dietitian should obtain a detailed diet history. Determine not only what foods the patient eats but also when, where, and how often the patient dines out. In addition, assess the sociocultural value of food. Use this information to assist the patient in making appropriate dietary choices when developing a diet plan. The National Heart, Lung, and Blood Institute provides helpful dietary guidelines for heart-healthy food preparation for people of various cultures (e.g., Hispanics, Native Americans, Asian Americans, African Americans). These are available online at *www.nhlbi.nih.gov/health/index.htm#recipes*. Diet and weight management recommendations must be individualized and culturally sensitive if the necessary changes are to be made.

The edema associated with chronic HF is often treated by dietary restriction of sodium. Teach the patient what foods are low and high in sodium and ways to enhance food flavors without the use of salt (e.g., substituting lemon juice, various spices). The degree of sodium restriction depends on the severity of the HF and the effectiveness of diuretic therapy. The Dietary Approaches to Stop Hypertension (DASH) diet is effective as a first-line therapy for many individuals with hyperten-

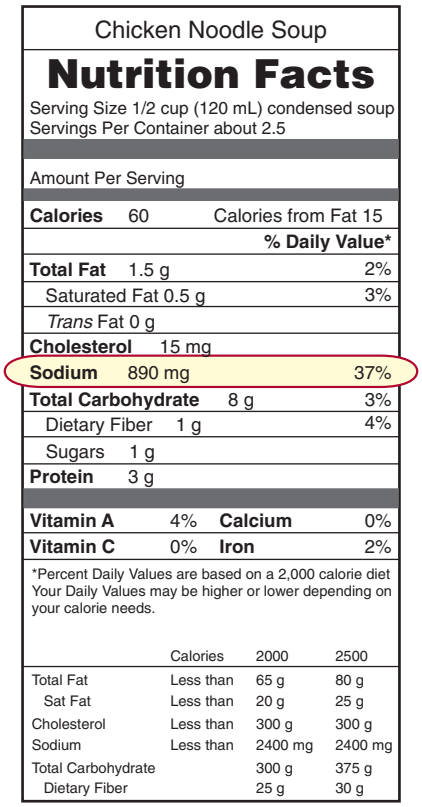
TABLE 35-8 NUTRITIONAL THERAPY

Low-Sodium Diets

General Principles

Do not add salt or seasonings containing sodium when preparing foods.*
Do not use salt at the table.*
Avoid high-sodium foods (e.g., canned soups, processed meats, cheese, frozen meals).
Limit milk products to 2 cups daily.

Sample Menu Plans for 2400-mg Sodium Diet



Breakfast	Sodium (mg)
⅔ cup bran cereal	161
(⅔ cup Shredded Wheat cereal)†	3
1 slice whole-wheat bread	149
1 medium banana	1
6 oz fruit yogurt, fat free	85
1 cup fat-free milk	126
2 tbs jelly	5
Coffee, 8 oz	5
Lunch	
Chicken breast sandwich	
2 slices (3 oz) chicken breast, skinless	65
2 slices whole wheat bread	299
1 slice (¾ oz) American cheese	328
(1 slice [¾ oz] Swiss cheese, natural)†	54
Large-leaf romaine lettuce	1
2 slices tomato	90
1 Tbsp mayonnaise, low fat	90
1 medium peach	7
Dinner	
¾ cup vegetarian spaghetti sauce	459
(6 oz no-salt-added tomato paste)†	260
1 cup spaghetti	1
3 tbs parmesan cheese	349
Spinach salad	
1 cup fresh spinach leaves	24
¼ cup fresh carrots (grated)	10
¼ cup fresh mushrooms (sliced)	1
2 Tbsp vinaigrette dressing	0
½ cup canned pears, juice pack	4
½ cup corn, cooked from frozen	4
Snack	
⅓ cup almonds	4
¼ cup dried apricots	3
6 oz fruit yogurt, fat free	85

*1 tsp of salt equals 2.3 g of sodium.
†Substitutes to reduce to 1500-mg sodium diet.

sion (see eTable 33-1: Your Guide to Lowering Your Blood Pressure With DASH). This diet is now also widely used for the patient with HF, with or without hypertension.

The average American adult's daily intake of sodium ranges from 7 to 15 g. A commonly prescribed diet for a patient with HF is a 2-g sodium diet (Table 35-8). All foods high in sodium (over 400 mg/serving) should be avoided. On this diet, processed meats, cheese, bread, cereals, canned soups, and canned vegetables must be limited. Teach the patient and caregiver how to read labels to look for sodium content (Fig. 35-5). The patient and caregiver should also be aware of the high sodium content of most restaurant foods.

Fluid restrictions are not commonly prescribed for the patient with mild to moderate HF. However, in moderate to severe HF and renal insufficiency, fluids are limited to less than 2 L/day.[18] Helping patients deal with thirst as a side effect of the medications is important. Suggest ice chips, gum, hard candy, or ice pops.

FIG. 35-5 Typical nutrition label. Note that a single serving (½ cup) provides more than one third of the daily recommended intake of sodium.

To monitor fluid status, instruct patients to weigh themselves at the same time each day, preferably before breakfast and using the same scale, while wearing the same type of clothing. This helps ensure valid comparisons from day to day and helps identify early signs of fluid retention. For patients with visual limitations, suggest scales with larger numbers or an audible response. Instruct patients to call the primary care provider if they see a weight gain of 3 lb (1.4 kg) over 2 days or a 3- to 5-lb (2.3-kg) gain over a week.[18,19]

NURSING MANAGEMENT HEART FAILURE

NURSING ASSESSMENT

Subjective and objective data that you should obtain from a patient with HF are presented in Table 35-9. Carefully review the patient's current prescription and over-the-counter medications. Assess for use of any nonsteroidal antiinflammatory drugs (NSAIDs), since they can contribute to sodium retention. In addition, review the patient's dietary habits to identify issues related to an exacerbation of HF. The patient's chronic health problems may act as exacerbating factors, affecting the plan of care and the timing and selection of therapies. For example, a patient with sleep apnea may not regularly use his or her continuous positive airway pressure device at night. This can worsen pulmonary or systemic hypertension and lead to an exacerbation of HF.

TABLE 35-9 NURSING ASSESSMENT

Heart Failure

Subjective Data

Important Health Information

Past health history: CAD (including recent MI), hypertension, cardiomyopathy, valvular or congenital heart disease, diabetes mellitus, hyperlipidemia, renal disease, thyroid or lung disease, rapid or irregular heart rate

Medications: Use of and adherence with any heart medications; use of diuretics, estrogens, corticosteroids, nonsteroidal antiinflammatory drugs, over-the-counter drugs, herbal supplements

Functional Health Patterns

Health perception–health management: Fatigue, depression, anxiety

Nutritional-metabolic: Usual sodium intake; nausea, vomiting, anorexia, stomach bloating; weight gain, ankle swelling

Elimination: Nocturia, decreased daytime urine output, constipation

Activity-exercise: Dyspnea, orthopnea, cough (e.g., dry, productive); palpitations; dizziness, fainting

Sleep-rest: Number of pillows used for sleeping; paroxysmal nocturnal dyspnea, insomnia

Cognitive-perceptual: Chest pain or heaviness; RUQ pain, abdominal discomfort; behavioral changes; visual changes

Objective Data

Integumentary

Cool, diaphoretic skin; cyanosis or pallor; peripheral edema (right-sided heart failure)

Respiratory

Tachypnea, crackles, rhonchi, wheezes; frothy, blood-tinged sputum

Cardiovascular

Tachycardia, S_3, S_4, murmurs; pulsus alternans, PMI displaced inferiorly and posteriorly, lifts and heaves, jugular venous distention

Gastrointestinal

Abdominal distention, hepatosplenomegaly, ascites

Neurologic

Restlessness, confusion, decreased attention or memory

Possible Diagnostic Findings

Altered serum electrolytes (especially Na^+ and K^+), ↑ BUN, creatinine, or liver function tests; ↑ NT-proBNP or BNP; chest x-ray demonstrating cardiomegaly, pulmonary congestion, and interstitial pulmonary edema; echocardiogram showing increased chamber size, decreased wall motion, decreased EF or normal EF with evidence of diastolic failure; atrial and ventricular enlargement on ECG; ↓ O_2 saturation

BNP, b-Type natriuretic peptide; *BUN,* blood urea nitrogen; *EF,* ejection fraction; *NT-proBNP,* N-terminal prohormone of BNP; *PMI,* point of maximal impulse; *RUQ,* right upper quadrant.

NURSING DIAGNOSES

Nursing diagnoses for the patient with HF include, but are not limited to, those presented in Nursing Care Plan 35-1.

PLANNING

The overall goals for the patient with HF include (1) a decrease in symptoms (e.g., shortness of breath, fatigue), (2) a decrease in peripheral edema, (3) an increase in exercise tolerance, (4) adherence with the medical regimen, and (5) no complications related to HF.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Communication and joint decision making among the patient, caregiver, and health care team are integral to selection and delivery of high-quality, patient-centered care. Currently, there is a campaign to aggressively identify and treat risk factors for HF to prevent or slow the progression of the disease.[22] For example, teach a patient with hypertension or hyperlipidemia measures to manage BP or cholesterol with medication, diet, and exercise. Patients with valvular disease should have valve replacement planned before lung congestion develops. Coronary revascularization procedures should be considered in patients with CAD. The use of antidysrhythmic drugs or pacing therapy is indicated for patients with serious dysrhythmias or conduction disturbances. In addition, encourage patients with HF to obtain vaccinations against the flu and pneumonia.

ACUTE INTERVENTION. Many persons with HF experience one or more episodes of ADHF. When they do, they are usually admitted through the ED, initially stabilized, and then managed in an ICU, an intermediate care unit, or a specialized HF unit with continuous ECG monitoring capability.

Successful HF management depends on several important principles: (1) HF is a progressive disease, and treatment plans are established along with quality-of-life goals; (2) symptom management is controlled by the patient with self-management tools (e.g., daily weights, drug regimens, diet and exercise plans); (3) salt and, at times, water must be restricted; (4) energy must be conserved; and (5) support systems are essential to the success of the entire treatment plan.[23] Nursing Care Plan 35-1 applies to the patient with stabilized ADHF or chronic HF.

Reduction of anxiety is an important nursing function, since anxiety may increase the SNS response and further increase myocardial workload. Reducing anxiety may be facilitated by a variety of nursing interventions and the use of sedatives (e.g., benzodiazepines).

The Joint Commission has selected core measures in the management of patients with HF to reflect standards of evidence-based care[24] (available at *www.jointcommission.org/assets/1/6/Heart%20Failure.pdf*). The AHA has developed a program, Get With the Guidelines—Heart Failure, to improve adherence to standards of evidence-based care of patients hospitalized with HF.[25] Together, these approaches work to ensure high-quality care for patients with HF.

AMBULATORY AND HOME CARE. HF is a chronic illness for most persons. When a patient is diagnosed with HF, care should focus on slowing the progression of the disease. Your important nursing responsibilities include (1) teaching the patient about the physiologic changes that have occurred, (2) helping the patient adapt to both physiologic and psychologic changes, and (3) integrating the patient and the caregiver in the overall care plan. Review the signs and symptoms of HF exacerbations with the patient and caregiver and provide them with a clear action plan should symptoms occur.[18] Early detection of worsening HF may help prevent an acute episode requiring hospitalization. A patient and caregiver guide for the patient with HF is presented in Table 35-10 on p. 782.

Patients with HF are at risk for anxiety and depression.[10] Emphasize to the patient that it is possible to live a productive life with this chronic health problem. Patients with HF are usually required to take medication for the rest of their lives. This often becomes difficult because a patient may be asymp-

NURSING CARE PLAN 35-1

Patient With Heart Failure

NURSING DIAGNOSIS **Impaired gas exchange** *related to* increased preload and alveolar-capillary membrane changes *as evidenced by* abnormal oxygen saturation, hypoxemia, dyspnea, tachypnea, tachycardia, restlessness, and patient's statement, "I am so short of breath"

PATIENT GOAL Maintains adequate O_2/CO_2 exchange at the alveolar-capillary membrane to meet O_2 needs of the body

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Respiratory Status: Gas Exchange	***Respiratory Monitoring***
• Cognitive status _____	• Monitor pulse oximetry, respiratory rate, rhythm, depth, and effort of respirations *to evaluate changes in respiratory status.*
• Ease of breathing _____	• Auscultate breath sounds, noting areas of decreased or absent ventilation and presence of adventitious sounds *to detect presence of pulmonary edema.*
• O_2 saturation _____	• Monitor for increased restlessness, anxiety, and work of breathing *to detect increasing hypoxemia.*
• PaO_2 _____	
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	***Oxygen Therapy*** • Administer supplemental O_2 or other noninvasive ventilator support (e.g., bilevel positive airway pressure [BiPAP]) as needed *to maintain adequate O_2 levels.* • Monitor the O_2 liter flow rate and placement of O_2 delivery device *to ensure O_2 is adequately delivered.* • Change O_2 delivery device from mask to nasal prongs during meals as tolerated *to sustain O_2 levels while eating.* • Monitor the effectiveness of O_2 therapy *to identify hypoxemia and establish range of O_2 saturation.*
• Dyspnea with exertion _____ • Dyspnea at rest _____ • Restlessness _____	***Positioning*** • Position patient to alleviate dyspnea (e.g., semi-Fowler's position), as appropriate, *to improve ventilation by decreasing venous return to the heart and increasing thoracic capacity.*
Measurement Scale 1 = Severe 2 = Substantial 3 = Moderate 4 = Mild 5 = None	

NURSING DIAGNOSIS **Decreased cardiac output** *related to* altered contractility, altered preload, and/or altered stroke volume *as evidenced by* decreased ejection fraction, increased CVP, decreased peripheral pulses, jugular venous distention, orthopnea, chest pain, S_3 and S_4 sounds, and oliguria

PATIENT GOAL Maintains adequate blood pumped by the heart to meet metabolic demands of the body

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Cardiac Pump Effectiveness	***Cardiac Care***
• Ejection fraction _____	• Perform a comprehensive assessment of peripheral circulation (e.g., check peripheral pulses, edema, capillary refill, color, and temperature of extremity) *to determine circulatory status.*
• Systolic BP _____	• Note signs and symptoms of decreased cardiac output (e.g., chest pain, S_3, S_4, jugular venous distention) *to detect changes in status.*
• Diastolic BP _____	• Monitor fluid balance (e.g., I/O and daily weight) *to evaluate renal perfusion.*
• Apical heart rate _____	• Continuously monitor cardiac rhythm *to detect dysrhythmias.*
• 24-hr I/O balance _____	• Monitor for dyspnea, fatigue, tachypnea, and orthopnea *to identify involvement of respiratory system.*
• CVP _____	• Instruct patient and caregivers on activity restriction and progression *to allay fears and anxiety.*
• Peripheral pulses _____	• Establish a supportive relationship with the patient and caregiver(s) *to promote adherence to the treatment plan.*
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	• Inform the patient of the purpose for and benefits of the prescribed activity and exercise.
• Neck vein distention _____ • Abnormal heart sounds _____ • Dysrhythmia _____ • Dyspnea _____ • Peripheral edema _____ • Pulmonary edema _____	
Measurement Scale 1 = Severe 2 = Substantial 3 = Moderate 4 = Mild 5 = None	

*Nursing diagnoses are listed in order of priority.

NURSING CARE PLAN 35-1—cont'd

Patient With Heart Failure

NURSING DIAGNOSIS **Excess fluid volume** *related to* increased venous pressure and decreased renal perfusion secondary to heart failure *as evidenced by* rapid weight gain, edema, adventitious breath sounds, oliguria, and patient's statement, "My ankles are so swollen"

PATIENT GOAL Experiences reduction or absence of edema and stable baseline weight

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Fluid Balance	***Hypervolemia Management***
• Stable body weight _____	• Administer prescribed diuretics, as appropriate, *to treat hypervolemia.*
• Peripheral pulses _____	• Monitor for therapeutic effect of diuretic (e.g., increased urine output, decreased CVP, decreased adventitious breath sounds) *to assess response to treatment.*
• Serum electrolytes _____	• Monitor potassium levels after diuresis *to detect excessive electrolyte loss.*
• BP _____	• Weigh patient daily and monitor trends *to evaluate effect of treatment.*
• CVP _____	• Monitor intake and output *to assess fluid status.*
• 24-hr I/O balance _____	• Monitor respiratory pattern for symptoms of respiratory difficulty *to detect pulmonary edema.*
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	• Monitor hemodynamic status, including CVP, MAP, PAWP, if available, *to evaluate effectiveness of therapy.*
	• Monitor changes in peripheral edema *to assess response to treatment.*
• Ascites _____	
• Neck vein distention _____	
• Peripheral edema _____	
• Adventitious breath sounds _____	
Measurement Scale 1 = Severe 2 = Substantial 3 = Moderate 4 = Mild 5 = None	

NURSING DIAGNOSIS **Activity intolerance** *related to* imbalance between O_2 supply and demand secondary to cardiac insufficiency and pulmonary congestion *as evidenced by* dyspnea, shortness of breath, weakness, increase in heart rate on exertion, and patient's statement, "I am too tired to get out of bed; I have no energy"

PATIENT GOAL Achieves a realistic program of activity that balances physical activity with energy-conserving activities

Outcomes (NOC)	Interventions (NIC) and *Rationales*
Activity Tolerance	***Energy Management***
• Pulse rate with activity _____	• Encourage alternate rest and activity periods *to reduce cardiac workload and conserve energy.*
• O_2 saturation with activity _____	• Provide calming diversionary activities to promote relaxation *to reduce O_2 consumption and to relieve dyspnea and fatigue.*
• Respiratory rate with activity _____	• Monitor patient's O_2 response (e.g., pulse rate, cardiac rhythm, and respiratory rate) to self-care or nursing activities *to determine level of activity that can be performed.*
• Systolic BP with activity _____	• Teach patient and caregiver techniques of self-care *that will minimize O_2 consumption (e.g., self-monitoring and pacing techniques for performance of ADLs).*
• Diastolic BP with activity _____	
• Ease of breathing with activity _____	***Activity Therapy***
• Ease of performing ADLs _____	• Collaborate with occupational and/or physical therapists *to plan and monitor activity or exercise program.*
• Skin color _____	• Determine patient's commitment to increasing frequency and/or range of activities or exercise *to provide patient with obtainable goals.*
Measurement Scale 1 = Severely compromised 2 = Substantially compromised 3 = Moderately compromised 4 = Mildly compromised 5 = Not compromised	

ADLs, Activities of daily living; *CVP,* central venous pressure; *I/O,* intake and output; *HF,* heart failure; *MAP,* mean arterial pressure; *PaO_2,* partial pressure of O_2 in arterial blood; *PAWP,* pulmonary artery wedge pressure.

tomatic when HF is under control. You must stress that the disease is chronic, and that medication must be continued to keep the HF under control.

Teach the patient the expected actions of the prescribed drugs and the signs of drug toxicity. Also teach the patient and caregiver how to take a pulse rate. The pulse rate should always be taken for 1 full minute. A pulse rate less than 50 beats/minute may be a contraindication to taking β-adrenergic blocker or a digitalis preparation unless directed by the health care provider. However, in the absence of symptoms (e.g., heart block, ventricular ectopy, syncope), a pulse rate less than 50 beats/minute may be acceptable. Include clear information about when a drug, especially β-blockers and digitalis, should be held and a health care provider called.

Teach the patient the symptoms of hypokalemia and hyperkalemia if diuretics that deplete or spare potassium are ordered. Frequently the patient who takes thiazide or loop diuretics is given supplemental potassium. It may also be appropriate to instruct patients in home BP monitoring, especially for those HF patients with hypertension.

TABLE 35-10 PATIENT & CAREGIVER TEACHING GUIDE

Heart Failure

Include the following instructions when teaching the patient and caregiver about the management of heart failure.

Dietary Therapy
- Consult the written diet plan and list of permitted and restricted foods.
- Examine labels to determine sodium content. Also examine the labels of over-the-counter drugs such as laxatives, cough medicines, and antacids for sodium content.
- Avoid using salt when preparing foods or adding salt to foods.
- Weigh yourself at the same time each day, preferably in the morning, using the same scale and wearing the same or similar clothes.
- Eat smaller, more frequent meals.

Activity Program
- Increase walking and other activities gradually, provided they do not cause fatigue or dyspnea. Consider a cardiac rehabilitation program.
- Avoid extremes of heat and cold.

Ongoing Monitoring
- Know the signs and symptoms of worsening heart failure (see eTable 35-1: Who Is the Patient With Heart Failure? Think FACES **[*F*atigue, limitation of *A*ctivities, chest *C*ongestion/cough, *E*dema, and *S*hortness of breath]**).
- Recall the symptoms experienced when illness began. Reappearance of previous symptoms may indicate a recurrence.
- Report immediately to health care provider any of the following:
  - Weight gain of 3 lb (1.4 kg) in 2 days, or 3-5 lb (2.3 kg) in a wk
  - Difficulty breathing, especially with exertion or when lying flat
  - Waking up breathless at night
  - Frequent dry, hacking cough, especially when lying down
  - Fatigue, weakness
  - Swelling of ankles, feet, or abdomen; swelling of face or difficulty breathing (if taking ACE inhibitors)
  - Nausea with abdominal swelling, pain, and tenderness
  - Dizziness or fainting
- Follow up with health care provider on regular basis.
- Consider joining a local support group with your family members and/or caregiver(s).

Health Promotion
- Obtain annual flu vaccination.
- Obtain pneumococcal vaccine (e.g., Pneumovax) and revaccination after 5 yr (for people at high risk of infection or serious disease).
- Develop plan to reduce risk factors (e.g., BP control, smoking cessation, weight reduction).

Rest
- Plan a regular daily rest and activity program.
- After exertion, such as exercise and ADLs, plan a rest period.
- Shorten working hours or schedule rest period during working hours.
- Avoid emotional upsets. Verbalize any concerns, fears, feelings of depression, etc., to health care provider.

Drug Therapy
- Take each drug as prescribed.
- Develop a system (e.g., daily chart, weekly pillbox) to ensure medications have been taken.
- Take pulse rate each day before taking medications (if appropriate). Know the parameters that your health care provider wants for your heart rate.
- Take BP at determined intervals (if appropriate). Know your target BP limits.
- Know signs and symptoms of orthostatic hypotension and how to prevent them (see Table 33-12).
- Know signs and symptoms of internal bleeding (bleeding gums, increased bruises, blood in stool or urine) and what to do if taking anticoagulants.
- Know own INR if taking warfarin (Coumadin) and how often to have blood monitored.

ACE, Angiotensin-converting enzyme; *INR,* international normalized ratio.

The physical therapist, occupational therapist, or you can instruct the patient in energy-conserving and energy-efficient behaviors after an evaluation of daily activities has been done. For example, once you understand the patient's daily routine, make suggestions to simplify work or modify an activity.

Exercise training (e.g., cardiac rehabilitation) improves symptoms of chronic HF but is often underprescribed. Exercise for patients with HF has been found to be safe and to improve the overall sense of well-being. It has also been correlated with mortality reduction.[25,26]

Frequently the patient needs a prescription for rest after an activity. Many hard-driving persons need the "permission" to not feel "lazy." Sometimes the patient may need to stop an activity that he or she enjoys. In such situations, help the patient explore alternative activities that cause less physical stress. Changes may be needed if situations produce an increased cardiac workload (e.g., frequent climbing of stairs). Help a patient identify areas where changes can be made and outside assistance obtained if needed.

Managing HF patients out of the hospital is a priority. Effective home health care can prevent or limit future hospitalizations by providing ongoing assessments (e.g., monitoring vital signs and weight, evaluating response to therapies).[23,27] Many agencies offer specialized programs dedicated to managing HF patients at home. For example, these programs may include the use of telehealth monitoring technology (e.g., electronic scale, BP cuff, pulse oximeter) to collect physiologic data (Fig. 35-6). The technology may also audibly ask the patient questions such as, "Are you short of breath today?" Results are transmitted telephonically or by computer to the agency. After the data are

FIG. 35-6 Home-based telehealth monitoring unit.

received and reviewed, the patient may be called to further assess the situation or schedule a visit.

Home health nurses frequently work with protocols set up with the patient's health care team. The protocols enable you and the patient to identify problems, such as an increase in weight or dyspnea, as evidence of worsening HF. To prevent hospitalization, interventions can be started such as changing medications and restricting fluids. Home health nursing care of HF patients is vital in reducing the number of hospitalizations, increasing functional capacity, and improving the quality of life.

PALLIATIVE AND END-OF-LIFE CARE. Health care providers are often reluctant to refer patients with advanced HF for palliative and end-of-life care. One reason is the difficulty in assessing the prognosis of the disease and the unpredictable trajectory of HF during the last few months of life.[28] In addition, patients and caregivers may have a poor understanding of the disease and may fail to recognize HF as a terminal illness.[29]

The ACCF/AHA provides guidelines for patients with end-stage HF (stage D).[1] Health care providers in collaboration with the patient and caregiver can select either extraordinary treatment interventions (e.g., experimental surgery or drugs) or palliative and hospice care. The guidelines recommend (1) ongoing patient and caregiver education regarding prognosis and survival, (2) patient and caregiver education about options for formulating advance directives (e.g., deactivation of ICD), and (3) continuity of medical care (e.g., continuous infusion of inotropes for symptom control).[1]

Patients are eligible for hospice when a physician certifies that they are likely to have a life expectancy of 6 months or less. Unfortunately, many eligible patients are not referred to hospice. There are a number of reasons for this, including a lack of understanding of the role of hospice, lack of an identifiable terminal phase for HF, and concerns about meeting hospice referral criteria.[30] African American and Hispanic patients with HF use hospice less than whites.[31]

The seriousness of the prognosis and the actual knowledge of the expected short life span are misunderstood by many HF patients and caregivers. Many health care providers and HF patients overestimate the life expectancy.[30] When caring for these patients, attempt to identify those who may be eligible for hospice and initiate a discussion among the patient, caregiver, and health care provider.

Because patients with end-stage HF may have multiple symptoms, your care should involve ongoing assessment and evaluation of interventions for effectiveness. Strategies involve patient and caregiver support, drug therapies, and nondrug therapies. Medications are continued unless they are not tolerated. The goals of providing comfort and relieving suffering remain priorities in the care of patients with end-stage HF. (Palliative and end-of-life care are discussed in Chapter 10.)

EVALUATION

The expected outcomes for the patient with HF are presented in Nursing Care Plan 35-1.

CARDIAC TRANSPLANTATION

Cardiac transplantation is the transfer of a healthy donor heart to a patient with a diseased heart. This surgery is used to treat a variety of terminal or end-stage heart conditions (Table 35-11). Retransplantation (i.e., a second or third heart transplant) is also done. In the United States, more than 2000 cardiac transplants are done each year. However, thousands more adults would benefit from a heart transplant if more donated hearts were available. The 1-year transplant survival rate is 88% for males and 86% for females. The 5-year survival rate is 73% for males and 69% for females.[32]

TABLE 35-11 INDICATIONS AND CONTRAINDICATIONS FOR CARDIAC TRANSPLANTATION*

Indications

- End-stage heart failure refractory to medical care
- Severe, decompensated, inoperable, valvular heart disease
- Recurrent life-threatening dysrhythmias not responsive to maximal interventions, including defibrillators
- Any other cardiac abnormalities that severely limit normal function and/or have a mortality risk of more than 50% at 2 yr

Absolute Contraindications

- Chronologic age over 70 yr or physiologic age over 65 yr
- Life-threatening illness (e.g., malignancy) that will limit survival to less than 5 yr despite therapy
- Advanced cerebral or peripheral vascular disease not amenable to correction
- Active infection, including HIV infection
- Severe pulmonary disease that will likely result in the patient being ventilator dependent after transplant

Relative Contraindications

- Uncontrolled diabetes mellitus with vascular and neurologic complications
- Irreversible liver or kidney dysfunction not explained by heart failure
- Morbid obesity
- Active substance abuse (e.g., alcohol, drugs, tobacco)
- Evidence of noncompliance with accepted medical practices
- Psychologic impairment
- Lack of social support network that can make long-term commitment for patient's welfare
- Unrealistic expectations by the patient or caregiver regarding transplant, its risks, and its benefits

*These are representative examples from various heart transplant centers.

Criteria for Selection

A careful selection process ensures that hearts are distributed fairly and to those who will benefit most from the donor heart. The United Network for Organ Sharing (UNOS) is in charge of a system that gives organs fairly to people. (UNOS is discussed in Chapter 14.)

Indications and contraindications for cardiac transplantation are identified in Table 35-11. Once an individual meets the criteria for cardiac transplantation, a complete physical examination and diagnostic workup are done. In addition, the patient and caregiver undergo a comprehensive psychologic evaluation. This includes assessing coping skills, support systems, and commitment to follow the rigorous regimen that is essential to a successful transplantation. The complexity of the transplant process may be overwhelming to a patient with inadequate support systems and a poor understanding of the lifestyle changes needed after transplant.

Donor and recipient matching is based on body and heart size and an immunologic evaluation. The immunologic assessment includes ABO blood type, antibody screen, panel-reactive antibody (PRA) level, and human leukocyte antigen typing (explained in Chapter 14).

ETHICAL/LEGAL DILEMMAS

Competence

Situation

M.T., a 60-year-old man, has been awaiting heart transplantation for 6 mo. He has been a patient in intensive care for 1 mo, since he has required a ventricular assist device for his failing heart. He recently suffered a stroke, which is a complication of the device. It left him paralyzed on his right side. He is only able to answer yes/no questions by shaking his head. He has required mechanical ventilation since his stroke. For the past 2 wk, hemodialysis has been required because of renal failure. Recently, when you suction him, he has tried to prevent the ventilator tubing from being reconnected by turning his head and biting down on the endotracheal tube. Although he does not have an advance directive, his wife and daughter tell you that, on numerous occasions before these events, he expressed that he would not want to live if he lost his independence. His wife and daughter request to have the mechanical ventilator withdrawn.

Ethical/Legal Points for Consideration

- Decisional capacity for informed consent related to treatment decisions involves four elements: (1) information provided about possible treatment options must be understandable to the patient; (2) possible outcomes of the various treatment options must be explained; (3) the patient must have the capacity to deliberate about the treatment choices and their consequences; and (4) the patient's treatment decision must be freely chosen and made without coercion.
- Legal competence, as determined by the courts, has a fairly low threshold. The ability to respond to questions by signaling a yes or no may be enough to demonstrate understanding of the questions, ability to discriminate between choices, and ability to communicate choices, providing that the answers make sense and are appropriate.
- Next of kin are the legal decision makers in the absence of advance directives if he is unable to make decisions for himself. However, decisional capacity should be tested without assuming it is absent.
- Some courts have accepted past assertions of preferences, past behavior, and assertions of their parties as evidence to support end-of-life preferences in the absence of advance directives.
- You need to be knowledgeable of your hospital or agency's documentation about the local jurisdiction's laws and regulations regarding informed consent and end-of-life decision making.

Discussion Questions

1. What would you do next given M.T.'s behavior and the information you obtained from his wife?
2. What are your feelings and concerns about participating in the care of a patient for whom withdrawal of treatment will result in death?

Once a person is accepted as a transplant candidate (this may happen quickly during an acute illness or after a longer period), he or she is placed on a transplant list. Patients may wait at home and receive ongoing medical care if their condition is stable. If not, they may require hospitalization for more intensive therapy. Unfortunately, the overall waiting period for a new heart is long. Many patients die while waiting for a transplant (see Ethical/Legal Dilemmas box above).

Bridge to Transplantation

Several devices are available as a bridge to transplantation, but only two have received U.S. Food and Drug Administration (FDA) approval for heart recovery after a life-threatening cardiac event. The AB5000 Circulatory Support System and the BVS 5000 Biventricular Support System provide temporary support for one or both sides of the heart in situations where the heart has failed but has the potential to recover (e.g., reversible HF, myocarditis, acute MI). The Thoratec VAD system can also support one or both ventricles, and it is approved as a bridging device for transplantation and for recovery of the heart after cardiac surgery.

Surgical Procedure

The surgical procedure actually involves multiple surgeries. First, the donor heart is retrieved. The donor is usually someone who has suffered irreversible brain injury *(brain death)*. Most donor hearts are obtained at sites distant from the institution performing the transplant. A team of physicians, nurses, and technicians goes to the hospital of the donor to remove donated organs once brain death has been determined. The retrieved organs are transported on ice until they can be implanted. For the heart, this is optimally less than 4 hours. Often the donor heart is flown to the recipient's hospital.

Next, the donated heart is implanted into the recipient. Two different approaches are used in this surgery. In the biatrial approach the recipient's damaged heart is removed at the midatrial level and the donor heart connected at the left atrium, pulmonary artery, aorta, and right atrium. In the bicaval approach the right atrium of the recipient's heart (with the sinoatrial node and maintenance of atrial conduction) is preserved, and then the donor heart is connected. Cardiopulmonary bypass is needed during the surgical procedure to maintain oxygenation and perfusion to vital organs.

Posttransplantation

After the transplant a variety of complications can occur, including a risk for SCD. Acute rejection is an immediate posttransplant complication, and immunosuppressive therapy is the key in posttransplant management. In the first year after transplantation the major causes of death are acute rejection and infection. Later on, malignancy (especially lymphoma) and cardiac vasculopathy (accelerated CAD) are major causes of death.[32]

Most immunosuppressive regimens include corticosteroids, calcineurin inhibitors (cyclosporine [Sandimmune, Neoral], tacrolimus (Prograf), and antiproliferative drugs (mycophenolate mofetil [CellCept]). (The mechanisms of action and side effects of these and other immunosuppressants are discussed in Chapter 14 and Table 14-16.) Because of the use of immunosuppressive therapy, infection is a primary complication after transplant surgery. On a long-term basis, immunosuppressive therapy increases the risk for cancer.[32]

To detect rejection, an EMB is obtained on a weekly basis for the first month, monthly for the following 6 months, and yearly thereafter. In this procedure, a catheter is inserted into the jugular vein and moved into the RV. The catheter uses a bioptome, a device with two small cups that can be closed, to remove small samples of heart muscle.[2,32]

Nursing management throughout the posttransplant period focuses on promoting patient adaptation to the transplant process, monitoring cardiac function, managing lifestyle changes, and providing ongoing teaching of the patient and the caregiver.

CASE STUDY

Heart Failure

iStockphoto/ Thinkstock

Patient Profile

J.E. is a 70-year-old Hispanic woman who was admitted to the intermediate care unit with complaints of increasing shortness of breath, fatigue, and weight gain.

Subjective Data

- History of hypertension for 20 yr
- History of MI at 58 yr of age
- Has experienced increasing shortness of breath, fatigue, and an unexplained 11-lb weight gain during the past 2 wk
- Had a respiratory tract infection 2 wk ago; has persistent cough and edema in legs
- Cannot climb a flight of stairs without getting short of breath
- Sleeps with head elevated on three pillows
- Lives alone, does not always remember to take medication

Objective Data

Physical Examination

- In respiratory distress, use of accessory muscles, respiratory rate 36 breaths/min
- Systolic heart murmur
- Bilateral crackles in all lung fields
- Cyanotic lips and extremities
- Skin cool and diaphoretic

Diagnostic Studies

- Chest x-ray results: cardiomegaly with right and left ventricular hypertrophy; fluid in lower lung fields
- Echocardiogram results: EF 20%

Collaborative Care

- Furosemide (Lasix) 40 mg IV bid
- Potassium 40 mEq PO bid
- Enalapril (Vasotec) 5 mg/day PO
- Nesiritide (Natrecor) 2 mcg/kg IV bolus followed by a continuous infusion of 0.01 mcg/kg/min
- Continuous ECG monitoring
- 2-g sodium diet
- Titrate O_2 to keep O_2 saturation >93%
- Monitor intake and output, and daily weights
- Serum electrolytes; cardiac enzymes q8hr × 3

Discussion Questions

1. Explain the pathophysiology of J.E.'s heart disease and symptomatology.
2. What clinical manifestations of ADHF did J.E. exhibit?
3. What is the significance of the findings of the diagnostic studies?
4. How would a serum NT-proBNP be beneficial in the diagnosis of ADHF?
5. Provide the rationale for each of the medical orders prescribed for J.E.
6. ***Priority Decision:*** Based on the assessment data presented, what are the priority nursing diagnoses? Identify any collaborative problems.
7. ***Priority Decision:*** What are your priority nursing interventions for J.E.?
8. ***Delegation Decision:*** Which of the interventions could be delegated to unlicensed assistive personnel (UAP)?
9. ***Priority Decision:*** What priority patient teaching measures should be instituted to prevent recurrence of ADHF and prepare J.E. for discharge?
10. ***Evidence-Based Practice:*** J.E. asks you why it is so important to "watch her salt." She tells you that food tastes better with salt. How would you respond to her?

evolve Answers and a corresponding concept map available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The nurse recognizes that primary manifestations of systolic failure include
   - **a.** ↓ EF and ↑ PAWP.
   - **b.** ↓ PAWP and ↑ EF.
   - **c.** ↓ pulmonary hypertension associated with normal EF.
   - **d.** ↓ afterload and ↓ left ventricular end-diastolic pressure.
2. A compensatory mechanism involved in HF that leads to inappropriate fluid retention and additional workload of the heart is
   - **a.** ventricular dilation.
   - **b.** ventricular hypertrophy.
   - **c.** neurohormonal response.
   - **d.** sympathetic nervous system activation.
3. You are caring for a patient with ADHF who is receiving IV dobutamine (Dobutrex). You know that this drug is ordered because it *(select all that apply)*
   - **a.** increases SVR.
   - **b.** produces diuresis.
   - **c.** improves contractility.
   - **d.** dilates renal blood vessels.
   - **e.** works on the β_1-receptors in the heart.
4. A patient with chronic HF and atrial fibrillation is treated with a digitalis glycoside and a loop diuretic. To prevent possible complications of this combination of drugs, what does the nurse need to do *(select all that apply)?*
   - **a.** Monitor serum potassium levels.
   - **b.** Teach the patient how to take a pulse rate.
   - **c.** Keep an accurate measure of intake and output.
   - **d.** Teach the patient about dietary restriction of potassium.
   - **e.** Withhold digitalis and notify health care provider if heart rate is irregular.
5. Patients with a heart transplantation are at risk for which complications in the first year after transplantation *(select all that apply)?*
   - **a.** Cancer
   - **b.** Infection
   - **c.** Rejection
   - **d.** Vasculopathy
   - **e.** Sudden cardiac death

1. a, 2. c, 3. c, e, 4. a, b, 5. b, c, e

LEARNING OUTCOMES

1. Examine the nursing management of patients requiring continuous electrocardiographic (ECG) monitoring.
2. Differentiate the clinical characteristics and ECG patterns of normal sinus rhythm, common dysrhythmias, and acute coronary syndrome (ACS).
3. Compare the nursing and collaborative management of patients with common dysrhythmias and ECG changes associated with ACS.
4. Differentiate between defibrillation and cardioversion, including indications for use and physiologic effects.
5. Describe the management of patients with pacemakers and implantable cardioverter-defibrillators.
6. Select appropriate interventions for patients undergoing electrophysiologic testing and radiofrequency catheter ablation therapy.

This chapter describes basic principles of electrocardiographic monitoring and recognition and treatment of common dysrhythmias. In addition, it presents ECG changes that are associated with acute coronary syndrome (ACS).

RHYTHM IDENTIFICATION AND TREATMENT

Your ability to recognize normal and abnormal cardiac rhythms, called **dysrhythmias,** is an essential nursing skill.[1] Prompt assessment of dysrhythmias and the patient's response to the rhythm is critical.

Conduction System

Four properties of cardiac cells enable the conduction system to start an electrical impulse, send it through the cardiac tissue, and stimulate muscle contraction (Table 36-1). The heart's conduction system consists of specialized neuromuscular tissue located throughout the heart (Fig. 32-4, *A*). A normal cardiac impulse begins in the sinoatrial (SA) node in the upper right atrium. It spreads over the atrial myocardium via interatrial and internodal pathways, causing atrial contraction. The impulse then travels to the atrioventricular (AV) node, through the bundle of His, and down the left and right bundle branches. It ends in the Purkinje fibers, which transmit the impulse to the ventricles.

Nervous Control of the Heart

The autonomic nervous system plays an important role in the rate of impulse formation, the speed of conduction, and the strength of cardiac contraction. The components of the auto-

Reviewed by Katrina Allen, RN, MSN, CCRN, Nursing Instructor, Faulkner State Community College: Division of Nursing, Fairhope and Bay Minette, Alabama; Barbara Pope, RN, MSN, PPCN, CCRN, Critical Care Educator, Independent Consultant, Albert Einstein Healthcare Network (retired), Philadelphia, Pennsylvania; and Regina Kukulski, RN, MSN, ACNS, BC, Nurse Educator Consultant, Thomas Edison State College, Capital Health Medical Center, Trenton, New Jersey.

nomic nervous system that affect the heart are the vagus nerve fibers of the parasympathetic nervous system and nerve fibers of the sympathetic nervous system.

Stimulation of the vagus nerve causes a decreased rate of firing of the SA node and slowed impulse conduction of the AV node. Stimulation of the sympathetic nerves increases SA node firing, AV node impulse conduction, and cardiac contractility.[2]

TABLE 36-1 PROPERTIES OF CARDIAC CELLS

Property	Definition
Automaticity	Ability to initiate an impulse spontaneously and continuously
Excitability	Ability to be electrically stimulated
Conductivity	Ability to transmit an impulse along a membrane in an orderly manner
Contractility	Ability to respond mechanically to an impulse

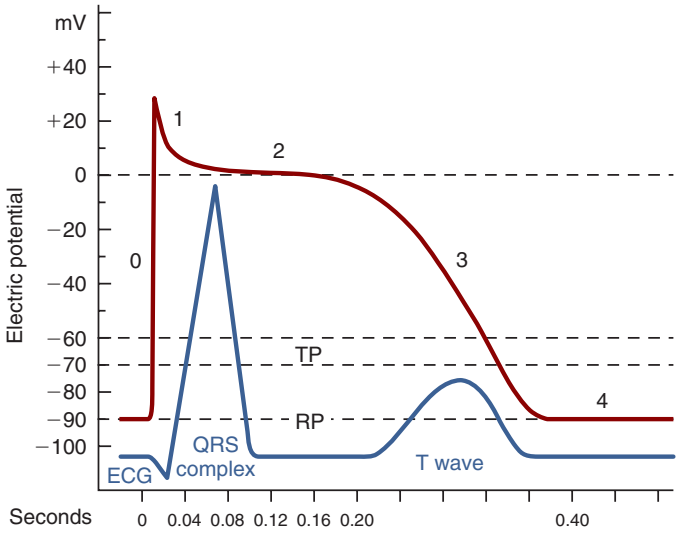

FIG. 36-1 Phases of the cardiac action potential. The electrical potential, measured in millivolts (mV), is indicated along the vertical axis of the graph. Time, measured in seconds (sec), is indicated along the horizontal axis. The action potential has five phases, labeled *0* through *4*. Each phase represents a particular electrical event or combination of electrical events. Phase 0 is the upstroke of rapid depolarization and corresponds with ventricular contraction. Phases 1, 2, and 3 represent repolarization. Phase 4 is known as complete repolarization (or the polarized state) and corresponds to diastole. *RP,* Resting membrane potential; *TP,* threshold membrane potential.

Electrocardiographic Monitoring

The *electrocardiogram* (ECG) is a graphic tracing of the electrical impulses produced in the heart. The waveforms on the ECG represent electrical activity produced by the movement of ions across the membranes of myocardial cells, representing depolarization and repolarization.

The membrane of a cardiac cell is semipermeable. This allows it to maintain a high concentration of potassium and a low concentration of sodium inside the cell. Outside the cell a high concentration of sodium and a low concentration of potassium exist. The inside of the cell, when at rest, or in the polarized state, is negative compared with the outside. When a cell or groups of cells are stimulated, the cell membrane changes its permeability. This allows sodium to move rapidly into the cell, making the inside of the cell positive compared with the outside *(depolarization)*. A slower movement of ions across the membrane restores the cell to the polarized state, called *repolarization*. Fig. 36-1 describes the phases of the cardiac action potential.

The ECG has 12 recording leads. Six of the leads measure electrical forces in the frontal plane. These are bipolar (positive or negative) leads I, II, and III; and unipolar (positive) leads aV_R, aV_L, and aV_F (Fig. 36-2, *A* and *B*). The remaining six unipolar leads (V_1 through V_6) measure the electrical forces in the horizontal plane (precordial leads) (Fig. 36-2, *C*). The 12-lead ECG may show changes suggesting structural changes, conduction disturbances, damage (e.g., ischemia, infarction), electrolyte imbalance, or drug toxicity. Obtaining 12 ECG views of the heart is also helpful in the assessment of dysrhythmias. Fig. 36-3 is an example of a normal 12-lead ECG.

One or more ECG leads can be used to continuously monitor a patient. The most common leads selected are leads II and V_1 (Fig. 36-4). A modified chest lead (MCL_1) is used when only three leads are available for monitoring (eFig. 36-1, showing MCL_1 lead placement, is available on the website for this chapter). MCL_1 is similar to V_1. Accurate interpretation of an ECG depends on the correct placement of the leads on the patient. The monitoring leads used are determined by the patient's clinical status.[3,4]

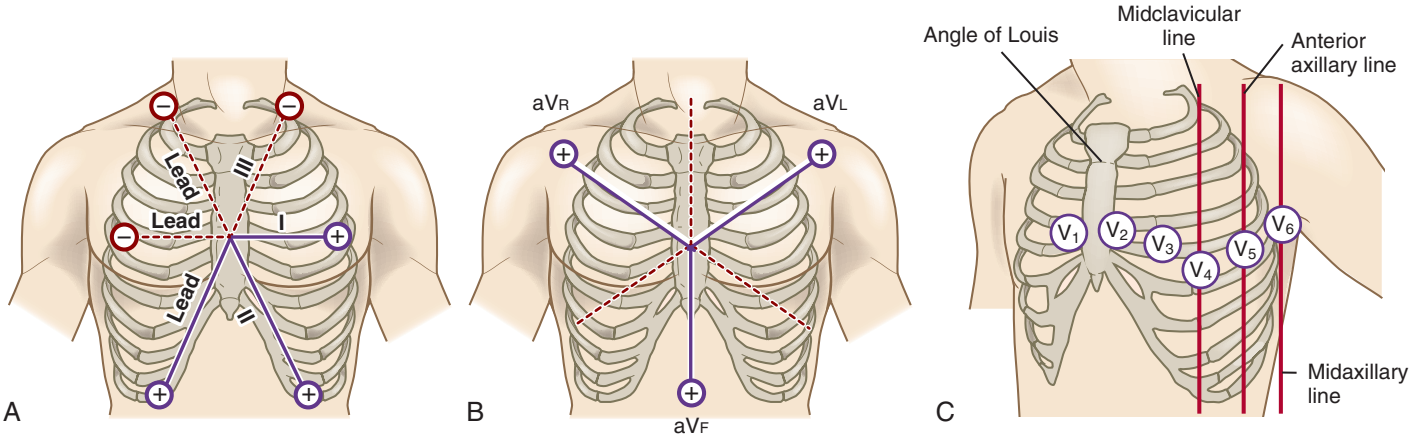

FIG. 36-2 **A,** Limb leads I, II, and III. These bipolar leads are located on the extremities. Illustrated are the angles from which these leads view the heart. **B,** Limb leads aV_R, aV_L, and aV_F. These unipolar leads use the center of the heart as their negative electrode. **C,** Placement for the unipolar chest leads: V_1, fourth intercostal space at the right sternal border; V_2, fourth intercostal space at the left sternal border; V_3, halfway between V_2 and V_4; V_4, fifth intercostal space at the left midclavicular line; V_5, fifth intercostal space at the left anterior axillary line; V_6, fifth intercostal space at the left midaxillary line.

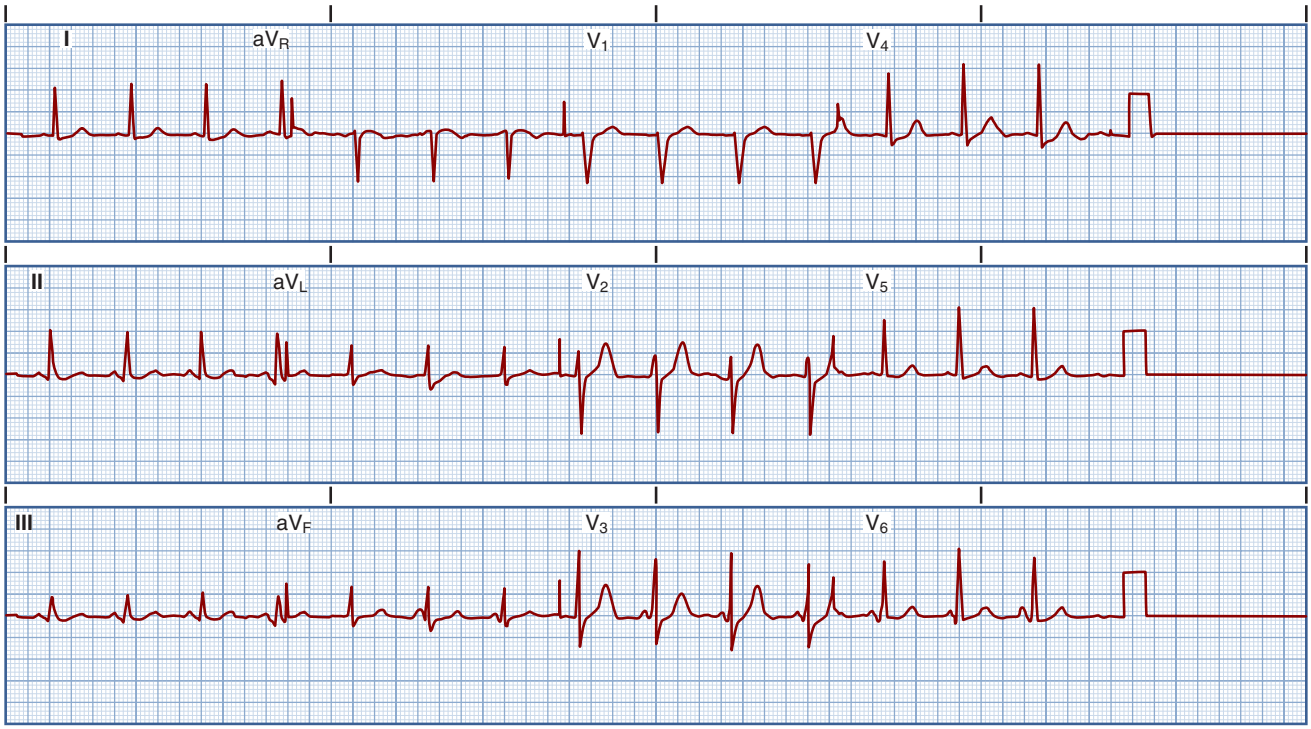

FIG. 36-3 Twelve-lead electrocardiogram showing a normal sinus rhythm.

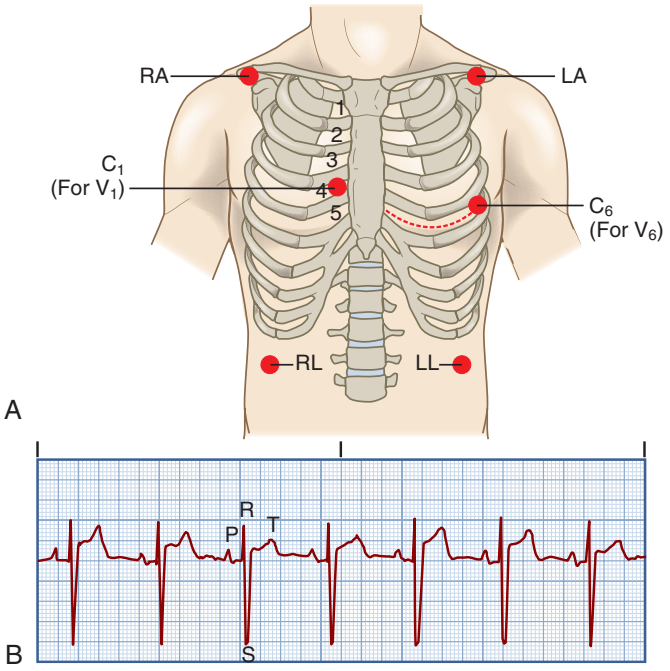

FIG. 36-4 **A,** Lead placement for V_1 or V_6 using a five-lead system. **B,** Typical ECG tracing in lead V_1. *C,* Chest; *LA,* left arm; *LL,* left leg; *RA,* right arm; *RL,* right leg.

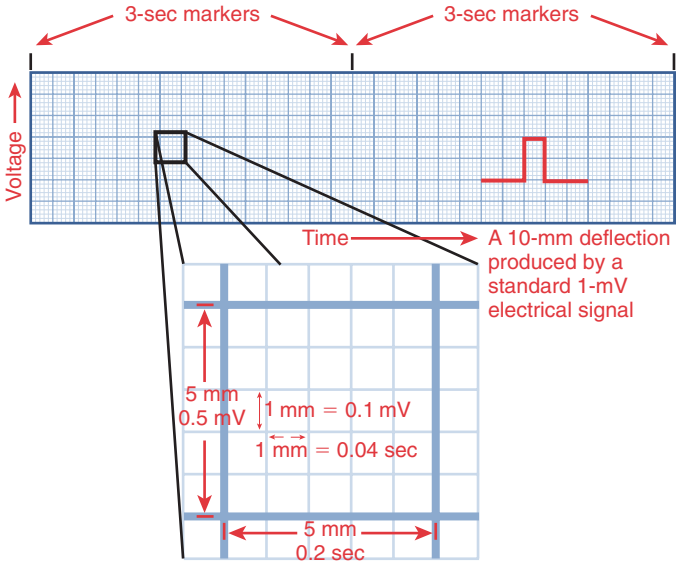

FIG. 36-5 Time and voltage on the electrocardiogram; 6-sec strip.

The monitor continuously displays the heart rhythm. ECG paper attached to the monitor records the ECG (i.e., rhythm strip). This provides a record of the patient's rhythm. It also allows for measurement of complexes and intervals and for assessment of dysrhythmias.

To correctly interpret an ECG, you measure time and voltage on the ECG paper. ECG paper consists of large (heavy lines) and small (light lines) squares (Fig. 36-5). Each large square consists of 25 smaller squares (five horizontal and five vertical). Horizontally, each small square (1 mm) represents 0.04 second. This means that one large square equals 0.20 second and that 300 large squares equal 1 minute. Vertically, each small square (1 mm) represents 0.1 millivolt (mV). This means that one large square equals 0.5 mV. Use these squares to calculate the heart rate (HR) and measure time intervals for the different ECG complexes.

You can use a variety of methods to calculate the HR from an ECG. The most accurate way is to count the number of QRS complexes in 1 minute. However, because this method is time

consuming, a simpler process is used. Note that every 3 seconds a marker appears on the ECG paper (see Fig. 36-5). Count the number of R-R intervals in 6 seconds and multiply that number by 10. (An R wave is the first upward [or positive] wave of the QRS complex.) This is the estimated number of beats per minute (Fig. 36-6).

Another method is to count the number of small squares between one R-R interval. Divide this number into 1500 to get the HR. Last, you can count the number of large squares between one R-R interval and divide this number into 300 to get the HR (see Fig. 36-6). All these methods are most accurate when the rhythm is regular.[1]

An additional way to measure distances on the ECG strip is to use calipers. Many times a P or an R wave will not fall directly on a light or heavy line. Place the fine points of the calipers exactly on the parts you need to measure and then move to another part of the strip for a more precise time measurement.

ECG leads consist of an electrode pad fixed with electrical conductive gel. Before placing these on the patient, you must properly prepare the skin. Clip excessive hair on the chest wall with scissors. Gently rub the skin with dry gauze until slightly pink. If the skin is oily, wipe with alcohol first. If the patient is diaphoretic, apply a skin protectant before placing the electrode.

You will see artifact on the monitor when leads and electrodes are not secure, or when there is muscle activity (e.g., shivering) or electrical interference. *Artifact* is a distortion of the baseline and waveforms seen on the ECG (Fig. 36-7). Accurate interpretation of heart rhythm is difficult when artifact is present. If artifact occurs, check the connections in the equipment. You may need to replace the electrodes if the conductive gel has dried out.

Telemetry Monitoring. **Telemetry monitoring** is the observation of a patient's HR and rhythm at a site distant from the patient. The use of this technology can help rapidly diagnose dysrhythmias, ischemia, or infarction. Two types of systems are used for telemetry monitoring. The first type, a centralized monitoring system, requires you or a telemetry technician to continuously observe a group of patients' ECGs at a central location. The second system of telemetry monitoring does not require constant surveillance. These systems have the capability of detecting and storing data. Advanced alarm systems provide different levels of detection of dysrhythmias, ischemia, or infarction.

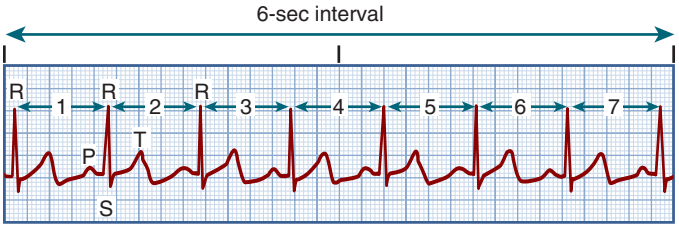

FIG. 36-6 When the rhythm is regular, heart rate can be easily determined. The estimated heart rate is 70 beats/min. NOTE: Recorded from lead II.

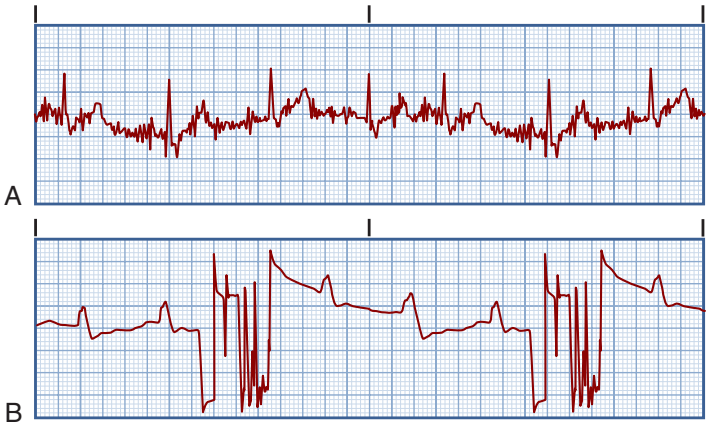

FIG. 36-7 Artifact. **A,** Muscle tremor. **B,** Loose electrodes.

INFORMATICS IN PRACTICE

Wireless ECG Monitoring

- Wireless electrocardiogram (ECG) monitoring systems continuously monitor and interpret the findings, sending an alert when patient rhythm and/or measurements fall outside of set parameters.
- Early detection of abnormal heart rhythms allows you time to assess the patient for signs of hemodynamic instability (e.g., chest pain, hypotension, palpitations, dyspnea) and determine the need to intervene (e.g., call the rapid response team).
- These systems can automatically save the pre-event portion of the ECG while continuing to record the post-event portion and send all of the information to the health care provider.
- Computerized monitoring systems are not fail-proof. Frequently assess all monitored patients for any signs of hemodynamic instability.

Assessment of Cardiac Rhythm

When assessing the cardiac rhythm, make an accurate interpretation and immediately evaluate the patient's clinical status. Assess the patient's hemodynamic response to any change in rhythm. This information will guide the selection of your interventions. Determination of the cause of dysrhythmias is a priority. For example, tachycardias may be the result of fever and may cause a decrease in cardiac output (CO) and hypotension. Electrolyte disturbances can cause dysrhythmias and, if not treated, can lead to life-threatening dysrhythmias. At all times, the patient, not the "monitor," must be assessed and treated.

Normal sinus rhythm refers to a rhythm that starts in the SA node at a rate of 60 to 100 times per minute and follows the normal conduction pathway (Fig. 36-8). Fig. 36-9 shows the components of a normal ECG tracing. Table 36-2 describes ECG waveforms and intervals, normal durations, and possible sources of disturbances in these features.

Electrophysiologic Mechanisms of Dysrhythmias

Dysrhythmias result from disorders of impulse formation, conduction of impulses, or both. The heart has specialized cells in the SA node, atria, AV node, and bundle of His and Purkinje fibers (His-Purkinje system), which can fire (discharge) spontaneously. This is termed *automaticity*. Normally, the SA node

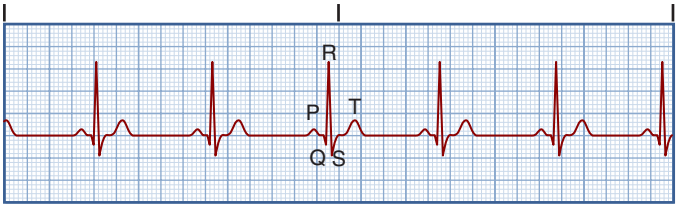

FIG. 36-8 Normal sinus rhythm. NOTE: Recorded from lead II.

is the pacemaker of the heart. It spontaneously fires 60 to 100 times per minute (Table 36-3). A secondary pacemaker from another site may fire in two ways. If the SA node fires more slowly than a secondary pacemaker, the electrical signals from the secondary pacemaker may "escape." The secondary pacemaker will then fire automatically at its intrinsic rate. These secondary pacemakers may start from the AV node at a rate of 40 to 60 times per minute or the His-Purkinje system at a rate of 20 to 40 times per minute.

Another way that secondary pacemakers can start is when they fire more rapidly than the normal pacemaker of the SA node. *Triggered beats* (early or late) may come from an *ectopic focus* or *accessory pathway* (area outside the normal conduction pathway) in the atria, AV node, or ventricles. This results in a dysrhythmia, which replaces the normal sinus rhythm.

The impulse started by the SA node or an ectopic focus must be conducted to the entire heart. The property of myocardial tissue that allows it to be depolarized by a stimulus is called *excitability.* This is an important part of the transmission of the

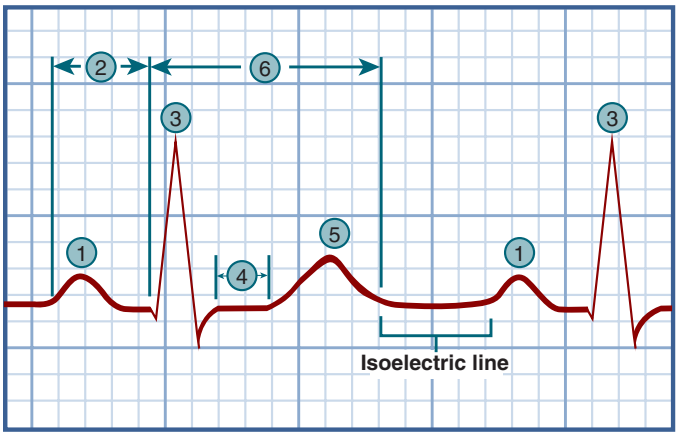

FIG. 36-9 The ECG tracing as seen in normal sinus rhythm. *1,* P wave; *2,* PR interval; *3,* QRS complex: Q wave, R wave, S wave; *4,* ST segment; *5,* T wave; *6,* QT interval. Isoelectric (flat) line or baseline represents the absence of electrical activity in the cardiac cells. (See Table 36-2 for timing of intervals.)

TABLE 36-2 ECG WAVEFORMS AND INTERVALS*

Description	Normal Duration (sec)	Source of Possible Variation
P Wave		
Represents time for the passage of the electrical impulse through the atrium causing atrial depolarization (contraction). Should be upright.	0.06-0.12	Disturbance in conduction within atria
PR Interval		
Measured from beginning of P wave to beginning of QRS complex. Represents time taken for impulse to spread through the atria, AV node and bundle of His, bundle branches, and Purkinje fibers, to a point immediately preceding ventricular contraction.	0.12-0.20	Disturbance in conduction usually in AV node, bundle of His, or bundle branches but can be in atria as well
QRS Complex		
Q wave: First negative (downward) deflection after the P wave, short and narrow, not present in several leads.	<0.03	MI may result in development of a pathologic Q wave that is wide (≥0.03 sec) and deep (≥25% of the height of the R wave)
R wave: First positive (upward) deflection in the QRS complex.	Not usually measured	
S wave: First negative (downward) deflection after the R wave.	Not usually measured	
QRS Interval		
Measured from beginning to end of QRS complex. Represents time taken for depolarization (contraction) of both ventricles (systole).	<0.12	Disturbance in conduction in bundle branches or in ventricles
ST Segment		
Measured from the S wave of the QRS complex to the beginning of the T wave. Represents the time between ventricular depolarization and repolarization (diastole). Should be isoelectric (flat).	0.12	Disturbances (e.g., elevation, depression) usually caused by ischemia, injury, or infarction
T Wave		
Represents time for ventricular repolarization. Should be upright.	0.16	Disturbances (e.g., tall, peaked; inverted) usually caused by electrolyte imbalances, ischemia, or infarction
QT Interval		
Measured from beginning of QRS complex to end of T wave. Represents time taken for entire electrical depolarization and repolarization of the ventricles.	0.34-0.43	Disturbances usually affecting repolarization more than depolarization and caused by drugs, electrolyte imbalances, and changes in heart rate

*Heart rate influences the duration of these intervals, especially those of the PR and QT intervals (e.g., QT interval shortens in duration as heart rate increases).
AV, Atrioventricular.

TABLE 36-3 INTRINSIC RATES OF THE CONDUCTION SYSTEM

Part of Conduction System	Rate
SA node	60-100 times/min
AV node	40-60 times/min
Bundle of His, Purkinje fibers	20-40 times/min

AV, Atrioventricular; *SA,* sinoatrial.

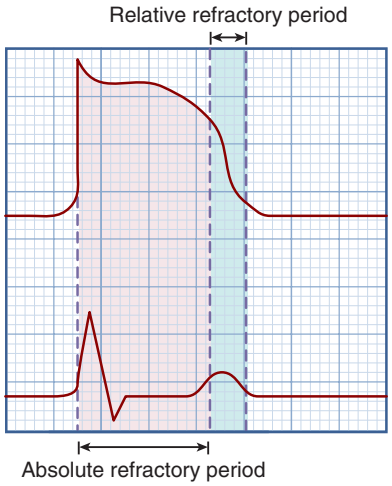

FIG. 36-10 Absolute and relative refractory periods correlated with the cardiac muscle's action potential and with an ECG tracing.

impulse from one cell to another. The level of excitability is determined by the length of time after depolarization that the tissues can be restimulated. The recovery period after stimulation is the *refractory phase* or period. The *absolute refractory phase* or period occurs when excitability is zero and the heart cannot be stimulated. The *relative refractory period* occurs slightly later in the cycle, and excitability is more likely. In states of *full excitability,* the heart is completely recovered. Fig. 36-10 shows the relationship between the refractory period and the ECG.

If conduction is depressed and some areas of the heart are blocked (e.g., by infarction), the unblocked areas are activated earlier than the blocked areas. When the block is unidirectional, this uneven conduction may allow the initial impulse to reenter areas that were previously not excitable but have recovered. The reentering impulse may be able to depolarize the atria and ventricles, causing a premature beat. If the reentrant excitation continues, tachycardia occurs.

Evaluation of Dysrhythmias

Dysrhythmias occur as the result of various abnormalities and disease states. The cause of a dysrhythmia influences the patient's treatment. Table 36-4 presents common causes of dysrhythmias. Table 36-5 presents a systematic approach to assessing a heart rhythm.

Dysrhythmias occurring in nonmonitored settings present management challenges. If the patient becomes symptomatic (e.g., chest pain), determination of the rhythm by cardiac monitoring is a high priority. Activate the emergency medical services (EMS) system. Table 36-6 outlines emergency care of the patient with a dysrhythmia.

In addition to continuous ECG monitoring during hospitalization, several other tests can assess dysrhythmias and the effectiveness of antidysrhythmia drug therapy. An electrophysiologic study, Holter monitoring, event monitoring (or loop recorder), exercise treadmill testing, and signal-averaged ECG can be performed on an inpatient or outpatient basis (see Table 32-6 for nursing care related to these tests).

An *electrophysiologic study* (EPS) can identify the causes of heart blocks, tachydysrhythmias (dysrhythmias with rates greater than 100 beats/minute), bradydysrhythmias (dysrhythmias with rates less than 60 beats/minute), and syncope. An EPS study can also locate accessory pathways and determine the effectiveness of antidysrhythmia drugs.

The Holter monitor continuously records the ECG while the patient is ambulatory and performing daily activities. The patient keeps a diary and records activities and any symptoms.

TABLE 36-4 COMMON CAUSES OF DYSRHYTHMIAS*

Cardiac Conditions	Other Conditions
• Accessory pathways	• Acid-base imbalances
• Cardiomyopathy	• Alcohol
• Conduction defects	• Caffeine, tobacco
• Heart failure	• Connective tissue disorders
• Myocardial ischemia, infarction	• Drug effects (e.g., antidysrhythmia drugs, stimulants, β-adrenergic blockers) or toxicity
• Valve disease	• Electric shock
	• Electrolyte imbalances (e.g., hyperkalemia, hypocalcemia)
	• Emotional crisis
	• Herbal supplements (e.g., areca nut, wahoo root bark, yerba maté)
	• Hypoxia
	• Metabolic conditions (e.g., thyroid dysfunction)
	• Near-drowning
	• Sepsis, shock
	• Toxins

*List is not all-inclusive.

TABLE 36-5 APPROACH TO ASSESSING HEART RHYTHM

When assessing a heart rhythm, use a consistent and systematic approach. One such approach includes the following:

1. Look for the P wave. Is it upright or inverted? Is there one for every QRS complex or more than one? Are atrial fibrillatory or flutter waves present?
2. Evaluate the atrial rhythm. Is it regular or irregular?
3. Calculate the atrial rate.
4. Measure the duration of the PR interval. Is it normal duration or prolonged?
5. Evaluate the ventricular rhythm. Is it regular or irregular?
6. Calculate the ventricular rate.
7. Measure the duration of the QRS complex. Is it normal duration or prolonged?
8. Assess the ST segment. Is it isoelectric (flat), elevated, or depressed?
9. Measure the duration of the QT interval. Is it normal duration or prolonged?
10. Note the T wave. Is it upright or inverted?

Additional questions to consider include the following:

1. What is the dominant or underlying rhythm and/or dysrhythmia?
2. What is the clinical significance of your findings?
3. What is the treatment for the particular rhythm?

TABLE 36-6 EMERGENCY MANAGEMENT

Dysrhythmias

Etiology	Assessment Findings	Interventions
See Table 36-4	• Irregular rate and rhythm; tachycardia, bradycardia • Decreased or increased blood pressure • Decreased O_2 saturation • Chest, neck, shoulder, back, jaw, or arm pain • Dizziness, syncope • Dyspnea • Extreme restlessness, anxiety • Decreased level of consciousness, confusion • Feeling of impending doom • Numbness, tingling of arms • Weakness and fatigue • Cold, clammy skin • Diminished peripheral pulses • Diaphoresis • Pallor • Palpitations • Nausea and vomiting	**Initial** • Ensure ABCs. • Administer O_2 via nasal cannula or non-rebreather mask. • Obtain baseline vital signs, including O_2 saturation. • Obtain 12-lead ECG. • Initiate continuous ECG monitoring. • Identify underlying rate and rhythm. • Identify dysrhythmia. • Establish IV access. • Obtain baseline laboratory studies (e.g., CBC, electrolytes). **Ongoing Monitoring** • Monitor vital signs, level of consciousness, O_2 saturation, and cardiac rhythm. • Anticipate need for administration of antidysrhythmia drugs and analgesics. • Anticipate need for intubation if respiratory distress is evident. • Prepare to initiate advanced cardiac life support (e.g., CPR, defibrillation, transcutaneous pacing).

ABCs, Airway, breathing, circulation.

Events in the diary are correlated with any dysrhythmias seen on the ECG. Use of event monitors has improved the evaluation of dysrhythmias in outpatients. Event monitors are recorders that the patient activates only when he or she experiences symptoms. New technology using smart phones can obtain and save ECG recordings and even detect atrial fibrillation.

Exercise treadmill testing evaluates the patient's heart rhythm during exercise. If exercise-induced dysrhythmias or ECG changes occur, they are analyzed and drug therapy evaluated.

The signal-averaged ECG identifies *late potentials* strongly suggesting that the patient may be at risk for developing serious ventricular dysrhythmias. Chapter 32 discusses the diagnostic procedures for assessment of the cardiovascular system and related nursing care.

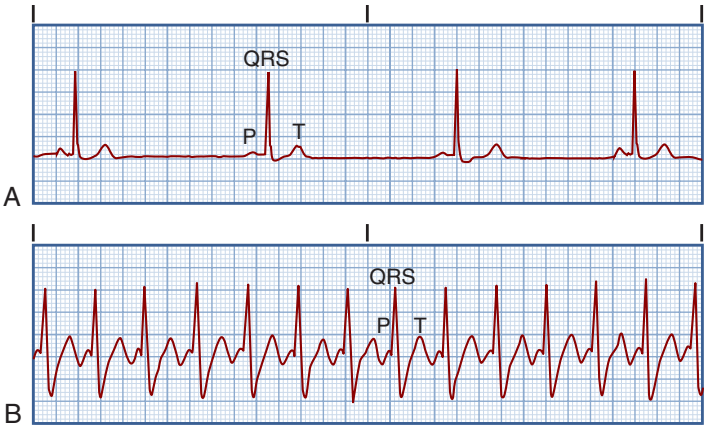

FIG. 36-11 **A,** Sinus bradycardia. **B,** Sinus tachycardia.

Types of Dysrhythmias

Figs. 36-11 to 36-19 provide examples of the ECG tracings of common dysrhythmias. Table 36-7 presents the descriptive characteristics.

Sinus Bradycardia. In *sinus bradycardia* the conduction pathway is the same as that in sinus rhythm but the SA node fires at a rate less than 60 beats/minute (Fig. 36-11, *A*). *Symptomatic bradycardia* refers to an HR that is less than 60 beats/minute and is inadequate for the patient's condition, causing the patient to experience symptoms (e.g., chest pain, syncope).

Clinical Associations. Sinus bradycardia may be a normal sinus rhythm in aerobically trained athletes and in some people during sleep. It also occurs in response to carotid sinus massage, Valsalva maneuver, hypothermia, increased intraocular pressure, vagal stimulation, and administration of certain drugs (e.g., β-adrenergic blockers, calcium channel blockers). Common disease states associated with sinus bradycardia are hypothyroidism, increased intracranial pressure, hypoglycemia, and inferior myocardial infarction (MI).

ECG Characteristics. In sinus bradycardia, HR is less than 60 beats/minute and the rhythm is regular. The P wave precedes each QRS complex and has a normal shape and duration. The PR interval is normal, and the QRS complex has a normal shape and duration.

Clinical Significance. The clinical significance of sinus bradycardia depends on how the patient tolerates it. Signs of symptomatic bradycardia include pale, cool skin; hypotension; weakness; angina; dizziness or syncope; confusion or disorientation; and shortness of breath.

Treatment. For the patient with symptoms, treatment consists of administration of atropine (an anticholinergic drug). If atropine (AtroPen) is ineffective, transcutaneous pacing, or a dopamine (Intropin) or epinephrine (Adrenalin) infusion is considered. Permanent pacemaker therapy may be needed. If bradycardia is due to drugs, these may need to be held, discontinued, or given in reduced dosages.

Sinus Tachycardia. The conduction pathway is the same in *sinus tachycardia* as that in normal sinus rhythm. The discharge rate from the sinus node increases because of vagal inhibition or sympathetic stimulation. The sinus rate is 101 to 200 beats/minute (Fig. 36-11, *B*).

Clinical Associations. Sinus tachycardia is associated with physiologic and psychologic stressors such as exercise, fever, pain, hypotension, hypovolemia, anemia, hypoxia, hypoglycemia, myocardial ischemia, heart failure (HF), hyperthyroidism, anxiety, and fear. It can also be an effect of drugs such as epinephrine, norepinephrine (Levophed), atropine, caffeine, theophylline (Theo-Dur), or hydralazine (Apresoline). In addition, many over-the-counter cold remedies have active ingredients (e.g., pseudoephedrine [Sudafed]) that can cause tachycardia.

TABLE 36-7 CHARACTERISTICS OF COMMON DYSRHYTHMIAS

Pattern	Rate and Rhythm	P Wave	PR Interval	QRS Complex
Normal sinus rhythm	60-100 beats/min and regular	Normal	Normal	Normal
Sinus bradycardia	<60 beats/min and regular	Normal	Normal	Normal
Sinus tachycardia	101-200 beats/min and regular	Normal	Normal	Normal
Premature atrial contraction	Usually 60-100 beats/min and irregular	Abnormal shape	Normal	Normal (usually)
Paroxysmal supraventricular tachycardia	150-220 beats/min and regular	Abnormal shape, may be hidden in the preceding T wave	Normal or shortened	Normal (usually)
Atrial flutter	*Atrial:* 200-350 beats/min and regular *Ventricular:* > or <100 beats/min and may be regular or irregular	Flutter (F) waves (sawtoothed pattern); more flutter waves than QRS complexes; may occur in a 2:1, 3:1, 4:1, etc., pattern	Not measurable	Normal (usually)
Atrial fibrillation	*Atrial:* 350-600 beats/min and irregular *Ventricular:* > or <100 beats/min and irregular	Fibrillatory (f) waves	Not measurable	Normal (usually)
Junctional dysrhythmias	40-180 beats/min and regular	Inverted, may be hidden in QRS complex	Variable	Normal (usually)
First-degree AV block	Normal and regular	Normal	>0.20 sec	Normal
Second-degree AV block				
• **Type I** (Mobitz I, Wenckebach heart block)	*Atrial:* Normal and regular *Ventricular:* Slower and irregular	Normal	Progressive lengthening	Normal QRS width, with pattern of one nonconducted (blocked) QRS complex
• **Type II** (Mobitz II heart block)	*Atrial:* Usually normal and regular *Ventricular:* Slower and regular or irregular	More P waves than QRS complexes (e.g., 2:1, 3:1)	Normal or prolonged	Widened QRS, preceded by ≥2 P waves, with nonconducted (blocked) QRS complex
Third-degree AV block (complete heart block)	*Atrial:* Regular but may appear irregular due to P waves hidden in QRS complexes *Ventricular:* 20-60 beats/min and regular	Normal, but no connection with QRS complex	Variable	Normal or widened, no relationship with P waves
Premature ventricular contraction (PVC)	Underlying rhythm can be any rate, regular or irregular rhythm, PVCs occur at variable rates	Not usually visible, hidden in the PVC	Not measurable	Wide and distorted
Ventricular tachycardia	150-250 beats/min and regular or irregular	Not usually visible	Not measurable	Wide and distorted
Accelerated idioventricular rhythm	40-100 beats/min and regular	Not usually visible	Not measurable	Wide and distorted
Ventricular fibrillation	Not measurable and irregular	Absent	Not measurable	Not measurable

AV, Atrioventricular.

ECG Characteristics. In sinus tachycardia, HR is 101 to 200 beats/minute and the rhythm is regular. The P wave is normal, precedes each QRS complex, and has a normal shape and duration. The PR interval is normal, and the QRS complex has a normal shape and duration.

Clinical Significance. The clinical significance of sinus tachycardia depends on the patient's tolerance of the increased HR. The patient may have dizziness, dyspnea, and hypotension because of decreased CO. Increased myocardial oxygen consumption is associated with an increased HR. Angina or an increase in infarction size may accompany sinus tachycardia in patients with coronary artery disease (CAD) or an acute MI.

Treatment. The underlying cause of tachycardia guides the treatment. For example, if the patient is experiencing tachycardia from pain, effective pain management is important to treat the tachycardia. In clinically stable patients, vagal maneuvers can be attempted. In addition, IV β-adrenergic blockers (e.g., metoprolol [Lopressor]), adenosine (Adenocard), or calcium channel blockers (e.g., diltiazem [Cardizem]) can be given to reduce HR and decrease myocardial oxygen consumption. In clinically unstable patients, synchronized cardioversion is used. (Cardioversion is discussed on p. 802.)

Premature Atrial Contraction. A **premature atrial contraction (PAC)** is a contraction starting from an ectopic focus in the atrium (i.e., a location other than the SA node) and coming sooner than the next expected sinus beat. The ectopic signal starts in the left or right atrium and travels across the atria by an abnormal pathway. This creates a distorted P wave (Fig. 36-12). At the AV node, it may be stopped (nonconducted PAC), delayed (lengthened PR interval), or conducted normally. If the signal moves through the AV node, in most cases it is conducted normally through the ventricles.

Clinical Associations. In a normal heart a PAC can result from emotional stress or physical fatigue or from the use

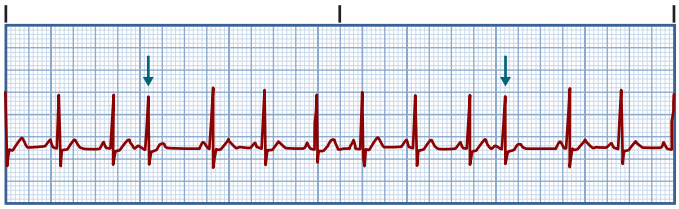

FIG. 36-12 Premature atrial contractions *(arrows).*

of caffeine, tobacco, or alcohol. A PAC can also result from hypoxia; electrolyte imbalances; and disease states such as hyperthyroidism, chronic obstructive pulmonary disease (COPD), and heart disease, including CAD and valvular disease.

ECG Characteristics. HR varies with the underlying rate and frequency of the PAC, and the rhythm is irregular. The P wave has a different shape from that of a P wave originating in the SA node, or it may be hidden in the preceding T wave. The PR interval may be shorter or longer than the PR interval coming from the SA node, but it is within normal limits. The QRS complex is usually normal. If the QRS interval is 0.12 second or more, abnormal conduction through the ventricles occurs.

Clinical Significance. In persons with healthy hearts, isolated PACs are not significant. Patients may report palpitations or a sense that their hearts "skipped a beat." In persons with heart disease, frequent PACs may indicate enhanced automaticity of the atria or a reentry mechanism. Such PACs may warn of or start more serious dysrhythmias (e.g., supraventricular tachycardia).

Treatment. Treatment depends on the patient's symptoms. Withdrawal of sources of stimulation such as caffeine or sympathomimetic drugs may be needed. β-Adrenergic blockers may be used to decrease PACs.

Paroxysmal Supraventricular Tachycardia. *Paroxysmal supraventricular tachycardia* (PSVT) is a dysrhythmia starting in an ectopic focus anywhere above the bifurcation of the bundle of His (Fig. 36-13). Identification of the ectopic focus is often difficult even with a 12-lead ECG, since it requires recording the dysrhythmia as it starts.

PSVT occurs because of a reentrant phenomenon (reexcitation of the atria when there is a one-way block). Usually a PAC triggers a run of repeated premature beats. *Paroxysmal* refers to an abrupt onset and ending. Termination is sometimes followed by a brief period of **asystole** (absence of all cardiac electrical activity). Some degree of AV block may be present. PSVT can occur in the presence of Wolff-Parkinson-White (WPW) syndrome, or "preexcitation." In this syndrome, there is extra conduction or accessory pathways.

Clinical Associations. In the normal heart, PSVT is associated with overexertion, emotional stress, deep inspiration, and stimulants such as caffeine and tobacco. PSVT is also associated with rheumatic heart disease, digitalis toxicity, CAD, and cor pulmonale.

ECG Characteristics. In PSVT the HR is 150 to 220 beats/minute, and the rhythm is regular or slightly irregular. The P wave is often hidden in the preceding T wave. If seen, it may have an abnormal shape. The PR interval may be shortened or normal, and the QRS complex is usually normal.

Clinical Significance. The clinical significance of PSVT depends on the associated symptoms. A prolonged episode and HR greater than 180 beats/minute will cause decreased CO because of reduced stroke volume. Symptoms often include hypotension, palpitations, dyspnea, and angina.

Treatment. Treatment for PSVT includes vagal stimulation and drug therapy. Common vagal maneuvers include Valsalva, carotid massage, and coughing. IV adenosine is the drug of choice to convert PSVT to a normal sinus rhythm. This drug has a short half-life (10 seconds) and is well tolerated.[5] IV β-adrenergic blockers, calcium channel blockers, and amiodarone (Cordarone) can also be used. If vagal stimulation and drug therapy are ineffective and the patient becomes hemodynamically unstable, synchronized cardioversion is used.[6] (Cardioversion is discussed on p. 802.)

DRUG ALERT: Adenosine (Adenocard)

- Injection site should be as close to the heart as possible (e.g., antecubital area).
- Give IV dose rapidly (over 1-2 sec) and follow with a rapid 20 mL normal saline flush.
- Monitor patient's ECG continuously. Brief period of asystole is common.
- Observe patient for flushing, dizziness, chest pain, or palpitations.

If PSVT recurs in patients with WPW syndrome, radiofrequency catheter ablation of the accessory pathway is the treatment of choice.[7] (Catheter ablation therapy is discussed on p. 805.)

Atrial Flutter. **Atrial flutter** is an atrial tachydysrhythmia identified by recurring, regular, sawtooth-shaped flutter waves that originate from a single ectopic focus in the right atrium or, less commonly, the left atrium (Fig. 36-14, *A*).

Clinical Associations. Atrial flutter rarely occurs in a healthy heart. It is associated with CAD, hypertension, mitral valve disorders, pulmonary embolus, chronic lung disease, cor

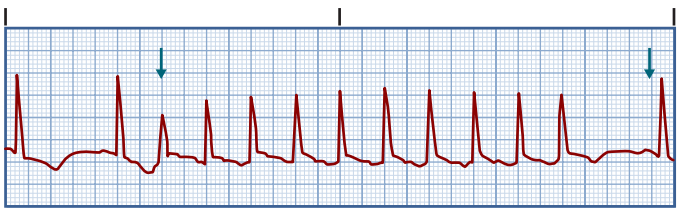

FIG. 36-13 Paroxysmal supraventricular tachycardia (PSVT). *Arrows* indicate beginning and ending of PSVT.

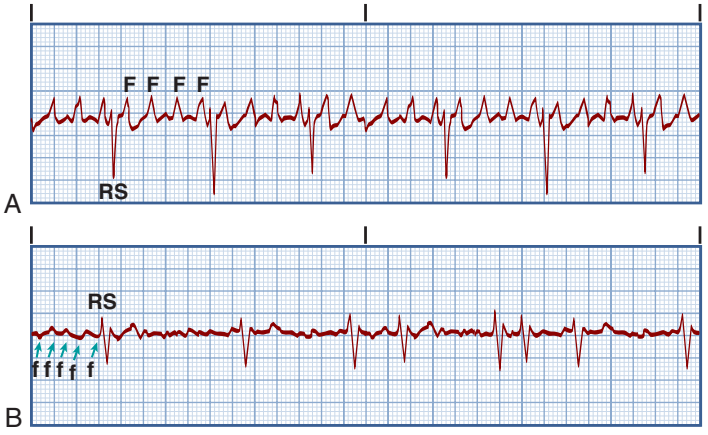

FIG. 36-14 **A,** Atrial flutter with a 4:1 conduction (four flutter *[F]* waves to each QRS complex). **B,** Atrial fibrillation with a controlled ventricular response. Note the chaotic fibrillatory *(f)* waves *(arrows)* between the RS complexes. NOTE: Recorded from lead V_1.

pulmonale, cardiomyopathy, hyperthyroidism, and the use of drugs such as digoxin, quinidine, and epinephrine.

ECG Characteristics. Atrial rate is 200 to 350 beats/minute. The ventricular rate varies based on the conduction ratio. In 2:1 conduction, the ventricular rate is typically found to be approximately 150 beats/minute. Atrial rhythm is regular, and ventricular rhythm is usually regular. The atrial flutter waves represent atrial depolarization followed by repolarization. The PR interval is variable and not measurable. The QRS complex is usually normal. Because the AV node can delay signals from the atria, there is usually some AV block in a fixed ratio of flutter waves to QRS complexes.

Clinical Significance. The high ventricular rates (greater than 100 beats/minute) and loss of the atrial "kick" (atrial contraction reflected by a sinus P wave) that are associated with atrial flutter decrease CO. This can cause serious consequences such as HF, especially in the patient with underlying heart disease. Patients with atrial flutter have an increased risk of stroke because of the risk of thrombus formation in the atria from the stasis of blood. Warfarin (Coumadin) is given to prevent stroke in patients who have atrial flutter.[6,7]

Treatment. The primary goal in treatment of atrial flutter is to slow the ventricular response by increasing AV block. Drugs used to control ventricular rate include calcium channel blockers and β-adrenergic blockers. Electrical cardioversion may be performed to convert the atrial flutter to sinus rhythm in an emergency (i.e., when the patient is clinically unstable) and electively. Antidysrhythmia drugs are used to convert atrial flutter to sinus rhythm (e.g., ibutilide [Corvert]) or to maintain sinus rhythm (e.g., amiodarone, flecainide [Tambocor], dronedarone [Multaq]).[5]

Radiofrequency catheter ablation is the treatment of choice for atrial flutter.[8] The procedure is done in the EPS laboratory and involves placing a catheter in the right atrium. With use of a low-voltage, high-frequency form of electrical energy, the tissue is ablated (or destroyed), the dysrhythmia is ended, and normal sinus rhythm is restored. (Catheter ablation is discussed on p. 802.)

Atrial Fibrillation. **Atrial fibrillation** is characterized by a total disorganization of atrial electrical activity because of multiple ectopic foci, resulting in loss of effective atrial contraction (Fig. 36-14, *B*). The dysrhythmia may be paroxysmal (i.e., beginning and ending spontaneously) or persistent (lasting more than 7 days).[9] Atrial fibrillation is the most common, clinically significant dysrhythmia with respect to morbidity and mortality rates and economic impact. It occurs in approximately 6% of people over age 65, and its prevalence increases with age.[10]

Clinical Associations. Atrial fibrillation usually occurs in the patient with underlying heart disease, such as CAD, valvular heart disease, cardiomyopathy, hypertensive heart disease, HF, and pericarditis. It often develops acutely with thyrotoxicosis, alcohol intoxication, caffeine use, electrolyte disturbances, stress, and cardiac surgery.

ECG Characteristics. During atrial fibrillation, the atrial rate may be as high as 350 to 600 beats/minute. P waves are replaced by chaotic, fibrillatory waves. Ventricular rate varies, and the rhythm is usually irregular. When the ventricular rate is between 60 and 100 beats/minute, it is atrial fibrillation with a *controlled ventricular response.* Atrial fibrillation with a ventricular rate greater than 100 beats/minute is atrial fibrillation with a *rapid (or uncontrolled) ventricular response.* The PR interval is not measurable, and the QRS complex usually has a normal shape and duration. At times, atrial flutter and atrial fibrillation may coexist.[1]

Clinical Significance. Atrial fibrillation results in a decrease in CO because of ineffective atrial contractions (loss of atrial kick) and/or a rapid ventricular response. Thrombi (clots) form in the atria because of blood stasis. An embolized clot may develop and move to the brain, causing a stroke. Atrial fibrillation accounts for as many as 17% of all strokes.[10]

Treatment. The goals of treatment include a decrease in ventricular response (to less than 100 beats/minute), prevention of stroke, and conversion to sinus rhythm, if possible. Ventricular rate control is a priority for patients with atrial fibrillation. Drugs used for rate control include calcium channel blockers (e.g., diltiazem), β-adrenergic blockers (e.g., metoprolol), dronedarone, and digoxin (Lanoxin).

For some patients, pharmacologic or electrical conversion of atrial fibrillation to a normal sinus rhythm may be considered

EVIDENCE-BASED PRACTICE

Applying the Evidence

G.D. is an 82-year-old woman with a new onset of atrial fibrillation and a history of mitral stenosis (high-risk factor). Her physician has ordered warfarin (Coumadin) to be started. You begin to teach her about the purpose and side effects of warfarin. She stops you and states that she will not take the medicine—she has heard too many stories about people bleeding from this medication. Furthermore, she tells you that she does not want to deal with the blood tests that are needed nor worry about what she eats. She states that she will continue to take her aspirin once a day as usual.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Warfarin (Coumadin) is the drug of choice to treat patients with atrial fibrillation who have one or more high-risk factors in order to prevent stroke.	Bleeding is a potential and serious side effect of warfarin and of dual antiplatelet therapy (ASA and clopidogrel).	G.D. does not want to take warfarin or clopidogrel because she is afraid of bleeding.
For patients for whom oral anticoagulation with warfarin is considered unsuitable (e.g., patient preference), the addition of clopidogrel (Plavix) to ASA reduces the risk of major vascular events (especially stroke) but increases the risk of major hemorrhage.	When taking warfarin, INR blood levels need to be checked on a regular basis. Patients should avoid drastic changes in diet, especially foods high in vitamin K (interfere with the action of warfarin).	In addition, she does not want to change her lifestyle to accommodate the changes that would be needed to use warfarin.

Your Decision and Action

You explain the risks of not taking the prescribed medicine (warfarin) or adequate medication (adding clopidogrel to her ASA therapy). She tells you that she understands completely. You support her choice and inform the physician of her decision.

TABLE 36-8 DRUG THERAPY

Anticoagulant Therapy for Atrial Fibrillation

Risk Category	Recommended Therapy
No risk factors	Aspirin, 81-325 mg/day
One moderate-risk factor	Aspirin, 81-325 mg/day, or warfarin*† (target INR 2.0-3.0)
Any high-risk factor or >1 moderate-risk factor	Warfarin* (target INR 2.0-3.0‡)
Level of Risk	**Risk Factors**
Moderate-risk factors	Age ≥75 yr
	Heart failure
	Hypertension
	LV ejection fraction ≤35%
	Diabetes mellitus
High-risk factors	Previous stroke, TIA, or embolism
	Mitral stenosis
	Prosthetic heart valve‡

Source: Wann LS, Curtis AB, January CT, et al: 2011 ACCF/AHA/HRS focused update on the management of patients with atrial fibrillation (updating the 2006 guideline): a report of the American College of Cardiology Foundation/American Heart Association Task Force on Practice Guidelines, *J Am Coll Cardiol* 57:223, 2011.
*Dabigatran (Pradaxa), a direct thrombin inhibitor, and apixaban (Eliquis) and rivaroxaban (Xarelto), factor Xa inhibitors, are oral anticoagulants approved for use in the treatment of nonvalvular atrial fibrillation only. To date, these drugs have not been incorporated into the guidelines.
†Clopidogrel (Plavix) may be added to aspirin therapy to reduce the risk of major vascular events in patients with atrial fibrillation if warfarin is considered unsuitable (e.g., patient preference, physician determines that patient cannot maintain adequate anticoagulation).

(e.g., reduced exercise tolerance with rate control drugs, contraindications to warfarin). The most common antidysrhythmia drugs used for conversion to and maintenance of sinus rhythm include amiodarone and ibutilide.[9]

Electrical cardioversion may convert atrial fibrillation to a normal sinus rhythm. If a patient is in atrial fibrillation for longer than 48 hours, anticoagulation therapy with warfarin is needed for 3 to 4 weeks before the cardioversion and for several weeks after successful cardioversion.[5] Anticoagulation therapy is necessary because the procedure can cause the clots to dislodge, placing the patient at risk for stroke. A transesophageal echocardiogram may be performed to rule out clots in the atria. If no clots are present, anticoagulation therapy may not be required before the cardioversion procedure.

If drugs or cardioversion does not convert atrial fibrillation to normal sinus rhythm, long-term anticoagulation therapy is required (Table 36-8). Warfarin is the drug of choice, and patients are monitored for therapeutic levels (e.g., international normalized ratio [INR]). Recently, alternatives to warfarin have been approved for anticoagulation therapy in patients with nonvalvular atrial fibrillation. These drugs do not require routine laboratory testing and include dabigatran (Pradaxa), apixaban (Eliquis), and rivaroxaban (Xarelto). (See Chapter 38 for discussion of anticoagulation therapy.)

For patients with drug-refractory atrial fibrillation or those who do not respond to electrical conversion, radiofrequency catheter ablation (similar to procedure for atrial flutter) and the Maze procedure are further options.[9] The Maze procedure is a surgical intervention that stops atrial fibrillation by interrupting the ectopic electrical signals that are responsible for the dysrhythmia. Incisions are made in both atria, and *cryoablation* (cold therapy) is used to stop the formation and conduction of these signals and restore normal sinus rhythm.[7]

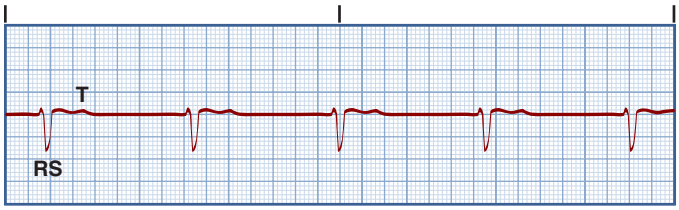

FIG. 36-15 Junctional escape rhythm. P wave is hidden in the RS complex. NOTE: Recorded from lead V_1.

Junctional Dysrhythmias. *Junctional dysrhythmias* refer to dysrhythmias that start in the area of the AV node. They result because the SA node fails to fire or the signal is blocked. When this occurs, the AV node becomes the pacemaker of the heart. The impulse from the AV node usually moves in a retrograde (backward) fashion. This produces an abnormal P wave that occurs just before or after the QRS complex or that is hidden in the QRS complex. The impulse usually moves normally through the ventricles. Junctional premature beats may occur, and they are treated in a manner similar to that for PACs. Other junctional dysrhythmias include junctional escape rhythm (Fig. 36-15), accelerated junctional rhythm, and junctional tachycardia. These dysrhythmias are treated according to the patient's tolerance of the rhythm and the patient's clinical condition.

Clinical Associations. Junctional dysrhythmias are often associated with CAD, HF, cardiomyopathy, electrolyte imbalances, inferior MI, and rheumatic heart disease. Certain drugs (e.g., digoxin, nicotine, amphetamines, caffeine) can also cause junctional dysrhythmias.

ECG Characteristics. In junctional escape rhythm the HR is 40 to 60 beats/minute. It is 61 to 100 beats/minute in accelerated junctional rhythm and 101 to 180 beats/minute in junctional tachycardia. Rhythm is regular. The P wave is abnormal in shape and inverted, or it may be hidden in the QRS complex (see Fig. 36-15). The PR interval is less than 0.12 second when the P wave precedes the QRS complex. The QRS complex is usually normal.

Clinical Significance. Junctional escape rhythms serve as a safety mechanism when the SA node has not been effective. Escape rhythms such as this should not be suppressed. Accelerated junctional rhythm is due to sympathetic stimulation to improve CO. Junctional tachycardia indicates a more serious problem. This rhythm may reduce CO, causing the patient to become hemodynamically unstable (e.g., hypotensive).

Treatment. Treatment varies according to the type of junctional dysrhythmia. If a patient has symptoms with a junctional escape rhythm, atropine can be used. In accelerated junctional rhythm and junctional tachycardia caused by drug toxicity, the drug is stopped. In the absence of digitalis toxicity, β-adrenergic blockers, calcium channel blockers, and amiodarone are used for rate control. Cardioversion should not be used.

First-Degree AV Block. *First-degree AV block* is a type of AV block in which every impulse is conducted to the ventricles but the time of AV conduction is prolonged (Fig. 36-16, *A*). After the impulse moves through the AV node, the ventricles usually respond normally.

Clinical Associations. First-degree AV block is associated with MI, CAD, rheumatic fever, hyperthyroidism, electrolyte imbalances (e.g., hypokalemia), vagal stimulation, and drugs such as digoxin, β-adrenergic blockers, calcium channel blockers, and flecainide.

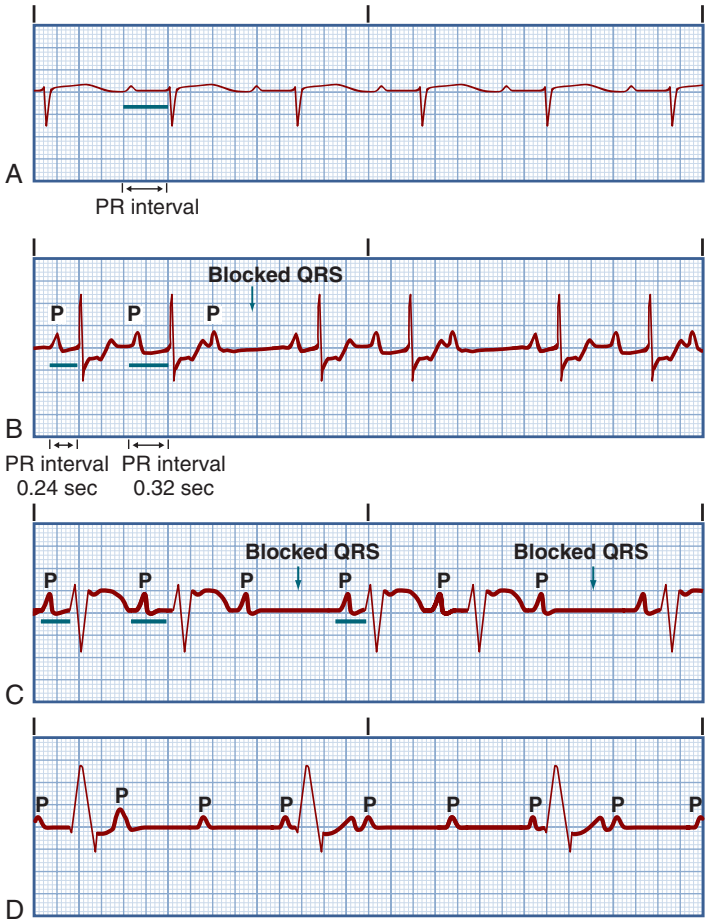

FIG. 36-16 Heart block. **A,** First-degree atrioventricular (AV) block with a PR interval of 0.40 sec. **B,** Second-degree AV block, type I, with progressive lengthening of the PR interval until a QRS complex is blocked. **C,** Second-degree AV block, type II, with constant PR intervals and variable blocked QRS complexes. **D,** Third-degree AV block. Note that there is no relationship between P waves and QRS complexes.

ECG Characteristics. In first-degree AV block, HR is normal and rhythm is regular. The P wave is normal, the PR interval is prolonged (greater than 0.20 second), and the QRS complex usually has a normal shape and duration.

Clinical Significance. First-degree AV block is usually not serious but can be a sign of higher degrees of AV block. Patients with first-degree AV block are asymptomatic.

Treatment. There is no treatment for first-degree AV block. Changes to potentially causative situations may be considered. Monitor patients for any new changes in heart rhythm (e.g., more serious AV block).

Second-Degree AV Block, Type I. *Type I second-degree AV block (Mobitz I* or *Wenckebach heart block)* includes a gradual lengthening of the PR interval. It occurs because of a prolonged AV conduction time until an atrial impulse is nonconducted and a QRS complex is blocked (missing) (Fig. 36-16, *B*). Type I AV block most commonly occurs in the AV node, but it can also occur in the His-Purkinje system.

Clinical Associations. Type I AV block may result from drugs such as digoxin or β-adrenergic blockers. It may also be associated with CAD and other diseases that can slow AV conduction.

ECG Characteristics. Atrial rate is normal, but ventricular rate may be slower because of nonconducted or blocked QRS complexes resulting in bradycardia. Once a ventricular beat is blocked, the cycle repeats itself with progressive lengthening of the PR intervals until another QRS complex is blocked. The rhythm appears on the ECG in a pattern of grouped beats. Ventricular rhythm is irregular. The P wave has a normal shape. The QRS complex has a normal shape and duration.

Clinical Significance. Type I AV block is usually a result of myocardial ischemia or inferior MI. It is generally transient and well tolerated. However, in some patients (e.g., acute MI) it may be a warning sign of a more serious AV conduction disturbance (e.g., complete heart block).

Treatment. If the patient is symptomatic, atropine is used to increase HR, or a temporary pacemaker may be needed, especially if the patient has had an MI. If the patient is asymptomatic, the rhythm is closely observed with a transcutaneous pacemaker on standby. Bradycardia is more likely to become symptomatic when hypotension, HF, or shock is present.

Second-Degree AV Block, Type II. In *type II second-degree AV block (Mobitz II heart block),* a P wave is nonconducted without progressive PR lengthening. This usually occurs when a block in one of the bundle branches is present (Fig. 36-16, *C*). On conducted beats, the PR interval is constant. Type II second-degree AV block is a more serious type of block in which a certain number of impulses from the SA node are not conducted to the ventricles. This occurs in ratios of 2:1, 3:1, and so on (i.e., two P waves to one QRS complex, three P waves to one QRS complex). It may occur with varying ratios.

Clinical Associations. Type II AV block is associated with rheumatic heart disease, CAD, anterior MI, and drug toxicity.

ECG Characteristics. Atrial rate is usually normal. Ventricular rate depends on the intrinsic rate and the degree of AV block. Atrial rhythm is regular, but ventricular rhythm may be irregular. The P wave has a normal shape. The PR interval may be normal or prolonged in duration and remains constant on conducted beats. The QRS complex is usually greater than 0.12 second because of bundle branch block.

Clinical Significance. Type II AV block often progresses to third-degree AV block and is associated with a poor prognosis. The reduced HR frequently results in decreased CO with subsequent hypotension and myocardial ischemia. Type II AV block is an indication for therapy with a permanent pacemaker.

Treatment. Insertion of a temporary pacemaker may be necessary before the insertion of a permanent pacemaker if the patient becomes symptomatic (e.g., hypotension, angina).[6,8] (Temporary pacemakers are discussed on pp. 804-805.)

Third-Degree AV Block. Third-degree AV block, or **complete heart block,** constitutes one form of AV dissociation in which no impulses from the atria are conducted to the ventricles (Fig. 36-16, *D*). The atria are stimulated and contract independently of the ventricles. The ventricular rhythm is an escape rhythm, and the ectopic pacemaker may be above or below the bifurcation of the bundle of His.

Clinical Associations. Third-degree AV block is associated with severe heart disease, including CAD, MI, myocarditis, cardiomyopathy, and some systemic diseases such as amyloidosis and progressive systemic sclerosis (scleroderma). Some drugs can also cause third-degree AV block, such as digoxin, β-adrenergic blockers, and calcium channel blockers.

ECG Characteristics. The atrial rate is usually a sinus rate of 60 to 100 beats/minute. The ventricular rate depends on the site of the block. If it is in the AV node, the rate is 40 to 60 beats/

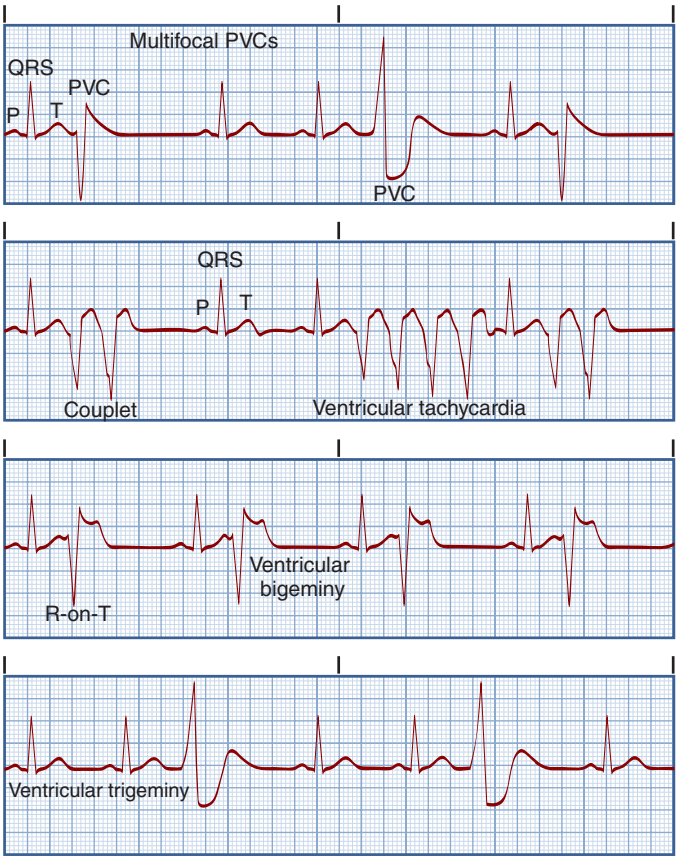

FIG. 36-17 Various forms of premature ventricular contractions (PVCs).

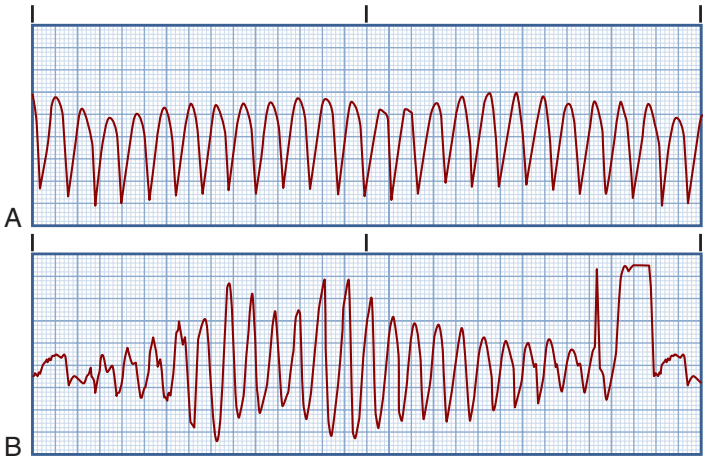

FIG. 36-18 Ventricular tachycardia. **A,** Monomorphic. **B,** Torsades de pointes (polymorphic).

minute, and if it is in the His-Purkinje system, it is 20 to 40 beats/minute. Atrial and ventricular rhythms are regular but unrelated to each other. The P wave has a normal shape. The PR interval is variable, and there is no relationship between the P wave and the QRS complex. The QRS complex is normal if an escape rhythm is initiated at the bundle of His or above. It is widened if an escape rhythm is initiated below the bundle of His.

Clinical Significance. Third-degree AV block usually results in reduced CO with subsequent ischemia, HF, and shock. Syncope from third-degree AV block may result from severe bradycardia or even periods of asystole.

Treatment. For symptomatic patients, a transcutaneous pacemaker is used until a temporary transvenous pacemaker can be inserted.[8] (Types of temporary pacemakers are discussed on pp. 804-805.) The use of drugs such as atropine, dopamine, and epinephrine is a temporary measure to increase HR and support blood pressure (BP) until temporary pacing is started. Patients need a permanent pacemaker as soon as possible.

Premature Ventricular Contractions. A **premature ventricular contraction (PVC)** is a contraction coming from an ectopic focus in the ventricles. It is the premature (early) occurrence of a QRS complex. A PVC is wide and distorted in shape compared with a QRS complex coming down the normal conduction pathway (Fig. 36-17). PVCs that arise from different foci appear different in shape from each other and are called *multifocal* PVCs. PVCs that have the same shape are called *unifocal* PVCs. When every other beat is a PVC, the rhythm is called *ventricular bigeminy.* When every third beat is a PVC, it is called *ventricular trigeminy.* Two consecutive PVCs are called a *couplet.*

Ventricular tachycardia (VT) occurs when there are three or more consecutive PVCs. *R-on-T phenomenon* occurs when a PVC falls on the T wave of a preceding beat. This is especially dangerous because the PVC is firing during the relative refractory phase of ventricular repolarization. Excitability of the cardiac cells increases during this time, and the risk for the PVC to start VT or ventricular fibrillation (VF) is great.

Clinical Associations. PVCs are associated with stimulants such as caffeine, alcohol, nicotine, aminophylline, epinephrine, isoproterenol, and digoxin. They are also associated with electrolyte imbalances, hypoxia, fever, exercise, and emotional stress. Disease states associated with PVCs include MI, mitral valve prolapse, HF, and CAD.

ECG Characteristics. HR varies according to intrinsic rate and number of PVCs. Rhythm is irregular because of premature beats. The P wave is rarely visible and is usually lost in the QRS complex of the PVC. Retrograde conduction may occur, and the P wave may be seen after the ectopic beat. The PR interval is not measurable. The QRS complex is wide and distorted in shape, lasting more than 0.12 second. The T wave is generally large and opposite in direction to the major direction of the QRS complex.

Clinical Significance. PVCs are usually not harmful in the patient with a normal heart. In heart disease, PVCs may reduce the CO and lead to angina and HF depending on frequency. Because PVCs in CAD or acute MI indicate ventricular irritability, assess the patient's physiologic response to PVCs. Obtain the patient's apical-radial pulse rate, since PVCs often do not generate a sufficient ventricular contraction to result in a peripheral pulse. This can lead to a pulse deficit.

Treatment. Treatment relates to the cause of the PVCs (e.g., oxygen therapy for hypoxia, electrolyte replacement). Assessment of the patient's hemodynamic status is important to determine if treatment with drug therapy is needed. Drug therapy includes β-adrenergic blockers, procainamide (Pronestyl), or amiodarone.

Ventricular Tachycardia. A run of three or more PVCs defines **ventricular tachycardia (VT).** It occurs when an ectopic focus or foci fire repeatedly and the ventricle takes control as the pacemaker. Different forms of VT exist, depending on QRS configuration. *Monomorphic* VT (Fig. 36-18, *A*) has QRS complexes that are the same in shape, size, and direction. *Polymorphic* VT occurs when the QRS complexes gradually change back

ETHICAL/LEGAL DILEMMAS

Scope and Standards of Practice

Situation

A young woman is admitted to the intensive care unit (ICU) from the emergency department after experiencing several episodes of nonsustained ventricular tachycardia (VT) attributed to a history of viral cardiomyopathy. While she is being stabilized in the ICU, she codes (pulseless VT) and intubation is indicated. A nurse anesthetist attempts to intubate her three times unsuccessfully. There is an unforeseen delay in the arrival of the anesthesiologist. P.F., an ICU nurse and former paramedic who is certified in advanced trauma life support (ATLS) and advanced cardiac life support (ACLS), attempts to intubate the patient and does so successfully. The next day the nursing supervisor questions P.F. about intubating the patient, since this is not within the scope of practice for an ICU nurse.

Ethical/Legal Points for Consideration

- The RN *Scope of Practice,* including rules and regulations that guide practice, are defined by individual state Boards of Nursing and can vary from state to state.
- Individual agencies also have policies and procedures that describe the scope of practice for nurses. These can be more restrictive than those of the state.
- *Scope and Standards of Practice* are also defined by professional nursing organizations (e.g., American Nurses Association, American Association of Critical-Care Nurses). These are authoritative statements that serve to define expected competent practice in various registered nurse (RN) roles (e.g., Scope and Standards for Nursing Administration).
- P.F. has had training, education, and certification beyond the usual nursing role.
- A life-threatening situation provides for extenuating circumstances.
- Negligence might have been a factor if P.F., who is a nurse with training and experience, had not acted.

Discussion Questions

1. What would you have done in this situation?
2. How would you respond to the nursing supervisor?
3. What are the legal ramifications for P.F. in this situation?
4. What are the ethical issues in this situation?

and forth from one shape, size, and direction to another over a series of beats. *Torsades de pointes* (French for "twisting of the points") is polymorphic VT associated with a prolonged QT interval of the underlying rhythm (Fig. 36-18, *B*).

VT may be sustained (longer than 30 seconds) or nonsustained (less than 30 seconds). The development of VT is an ominous sign. It is a life-threatening dysrhythmia because of decreased CO and the possibility of development of VF, which is lethal.

Clinical Associations. VT is associated with MI, CAD, significant electrolyte imbalances, cardiomyopathy, mitral valve prolapse, long QT syndrome, drug toxicity, and central nervous system disorders. This dysrhythmia can be seen in patients who have no evidence of cardiac disease.

ECG Characteristics. Ventricular rate is 150 to 250 beats/minute. Rhythm may be regular or irregular. AV dissociation may be present, with P waves occurring independently of the QRS complex. The atria may be depolarized by the ventricles in a retrograde fashion. The P wave is usually buried in the QRS complex, and the PR interval is not measurable. The QRS complex is distorted in appearance and wide (greater than 0.12 second in duration). The T wave is in the opposite direction of the QRS complex (see Fig. 36-18).

Clinical Significance. VT can be stable (patient has a pulse) or unstable (patient is pulseless). Sustained VT causes a severe decrease in CO because of decreased ventricular diastolic filling times and loss of atrial contraction. This results in hypotension, pulmonary edema, decreased cerebral blood flow, and cardiopulmonary arrest. The dysrhythmia must be treated quickly, even if it occurs only briefly and stops abruptly. Episodes may recur if prophylactic treatment is not started. VF may also develop.

Treatment. Precipitating causes (e.g., electrolyte imbalances, ischemia) must be identified and treated. If the VT is monomorphic and the patient is clinically stable (i.e., pulse is present) and has preserved left ventricular function, IV procainamide, sotalol, or amiodarone is used. These drugs can also be used if the VT is polymorphic with a normal baseline QT interval.

Polymorphic VT with a prolonged baseline QT interval is treated with IV magnesium, isoproterenol, phenytoin (Dilantin), or antitachycardia pacing (discussed later in this chapter). Drugs that prolong the QT interval (e.g., dofetilide [Tikosyn]) should be discontinued. Cardioversion is used if drug therapy is ineffective.

VT without a pulse is a life-threatening situation. It is treated in the same manner as VF. Cardiopulmonary resuscitation (CPR) and rapid defibrillation are the first lines of treatment, followed by the administration of vasopressors (e.g., epinephrine) and antidysrhythmics (e.g., amiodarone) if defibrillation is unsuccessful.[6]

An *accelerated idioventricular rhythm* (AIVR) can develop when the intrinsic pacemaker rate (SA node or AV node) becomes less than that of a ventricular ectopic pacemaker. The rate is between 40 and 100 beats/minute. It is most commonly associated with acute MI and reperfusion of the myocardium after thrombolytic therapy or angioplasty of coronary arteries. It can be seen with digitalis toxicity. In the setting of acute MI, AIVR is usually self-limiting and well tolerated, and it requires no treatment. If the patient becomes symptomatic (e.g., hypotensive, chest pain), atropine can be considered. Temporary pacing may be required. Drugs that suppress ventricular rhythms (e.g., amiodarone) should not be used, since these can terminate the ventricular rhythm and further reduce the HR.

Ventricular Fibrillation. **Ventricular fibrillation (VF)** is a severe derangement of the heart rhythm characterized on ECG by irregular waveforms of varying shapes and amplitude (Fig. 36-19). This represents the firing of multiple ectopic foci in the ventricle. Mechanically the ventricle is simply "quivering," with no effective contraction, and consequently no CO occurs. VF is a lethal dysrhythmia.

Clinical Associations. VF occurs in acute MI and myocardial ischemia and in chronic diseases such as HF and cardiomyopathy. It may occur during cardiac pacing or cardiac catheterization procedures because of catheter stimulation of the ventricle. It may also occur with coronary reperfusion

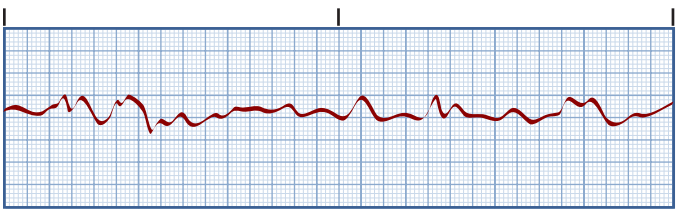

FIG. 36-19 Ventricular fibrillation.

after thrombolytic therapy. Other clinical associations are electric shock, hyperkalemia, hypoxemia, acidosis, and drug toxicity.

ECG Characteristics. HR is not measurable. Rhythm is irregular and chaotic. The P wave is not visible, and the PR interval and the QRS interval are not measurable.

Clinical Significance. VF results in an unresponsive, pulseless, and apneic state. If it is not rapidly treated, the patient will not recover.

Treatment. Treatment consists of immediate initiation of CPR and advanced cardiac life support (ACLS) with the use of defibrillation and definitive drug therapy (e.g., epinephrine, vasopressin [Pitressin]). There should be no delay in using a defibrillator once available.

Asystole. Asystole represents the total absence of ventricular electrical activity. Occasionally, P waves are seen. No ventricular contraction occurs because depolarization does not occur. Patients are unresponsive, pulseless, and apneic. Asystole is a lethal dysrhythmia that requires immediate treatment. VF may masquerade as asystole. Always assess the rhythm in more than one lead. The prognosis of a patient with asystole is extremely poor.

Clinical Associations. Asystole is usually a result of advanced cardiac disease, a severe cardiac conduction system disturbance, or end-stage HF.

Clinical Significance. Generally the patient with asystole has end-stage heart disease or has a prolonged arrest and cannot be resuscitated.

Treatment. Treatment consists of CPR with initiation of ACLS measures. These include definitive drug therapy with epinephrine and/or vasopressin, and intubation.

Pulseless Electrical Activity. *Pulseless electrical activity* (PEA) is a situation in which organized electrical activity is seen on the ECG, but there is no mechanical activity of the ventricles and the patient has no pulse. It is the most common dysrhythmia seen after defibrillation. Prognosis is poor unless the underlying cause is quickly identified and treated. The most common causes of PEA include hypovolemia, hypoxia, metabolic acidosis, hyperkalemia, hypokalemia, hypoglycemia, hypothermia, toxins (e.g., drug overdose), cardiac tamponade, thrombosis (e.g., MI, pulmonary embolus), tension pneumothorax, and trauma. Treatment begins with CPR followed by drug therapy (e.g., epinephrine) and intubation. Correcting the underlying cause is critical to prognosis.

Sudden Cardiac Death. The term *sudden cardiac death* (SCD) refers to death from a cardiac cause. Most SCDs result from ventricular dysrhythmias, specifically VT or VF. (SCD is discussed in Chapter 34.)

Prodysrhythmia. Antidysrhythmia drugs can cause life-threatening dysrhythmias similar to those for which they are given. This concept is termed *prodysrhythmia.* The patient who has severe left ventricular dysfunction is the most susceptible to prodysrhythmias. Digoxin and class IA, IC, and III antidysrhythmia drugs can cause a prodysrhythmic response.[5] The first several days of drug therapy are the vulnerable period for developing prodysrhythmias. For this reason, many oral antidysrhythmia drug regimens are started in a monitored hospital setting.

Antidysrhythmia Drugs

Table 36-9 categorizes antidysrhythmia drugs by their primary effects on the cardiac cells and the ECG.

TABLE 36-9 DRUG THERAPY

Antidysrhythmia Drugs

Drug	Actions*	Effects on ECG
Class I: Sodium Channel Blockers	Decrease impulse conduction in the atria, ventricles, and His-Purkinje system	—
Class IA disopyramide (Norpace) procainamide (Pronestyl) quinidine (Quinora)	Delay repolarization	Widened QRS and prolonged QT interval
Class IB mexiletine (Mexitil) phenytoin (Dilantin)	Accelerate repolarization	Little or no effect on ECG
Class IC flecainide (Tambocor) propafenone (Rythmol)	Decrease impulse conduction	Pronounced prodysrhythmic actions, widened QRS, prolonged QT interval
Class II: β-Adrenergic Blockers esmolol (Brevibloc) metoprolol (Lopressor) propranolol (Inderal)	Decrease automaticity of the SA node, slow impulse conduction in AV node, reduce atrial and ventricular contractility	Bradycardia, prolonged PR interval, AV block
Class III: Potassium Channel Blockers amiodarone (Cordarone) bretylium (Bretylol) dofetilide (Tikosyn) ibutilide (Corvert) sotalol† (Betapace)	Delay repolarization, resulting in prolonged duration of action potential and refractory period	Prolonged PR and QT intervals, widened QRS, bradycardia
Class IV: Calcium Channel Blockers diltiazem (Cardizem) verapamil (Calan)	Decrease automaticity of SA node, delay AV node conduction; reduce myocardial contractility	Bradycardia, prolonged PR interval, AV block
Other Antidysrhythmia Drugs		
adenosine (Adenocard) digoxin (Lanoxin)	Decrease conduction through AV node, reduce automaticity of SA node	Prolonged PR interval, AV block
dronedarone (Multaq)‡	Suppresses atrial dysrhythmias though mechanism is unknown	Prolonged QT interval
Magnesium	Decreases impulse conduction through AV node	AV block

*Antidysrhythmia drugs have a direct effect on the various phases of the action potential (see Fig. 36-1).
†Sotalol has both class II and class III properties.
‡Dronedarone has class I-IV properties.
AV, Atrioventricular; *SA,* sinoatrial.

Defibrillation

Defibrillation is the treatment of choice to end VF and pulseless VT. It is most effective when the myocardial cells are not anoxic or acidotic. Rapid defibrillation (within 2 minutes) is critical to a successful patient outcome. Defibrillation involves the passage of an electric shock through the heart to depolarize the cells of the myocardium. The goal is that the following repolarization

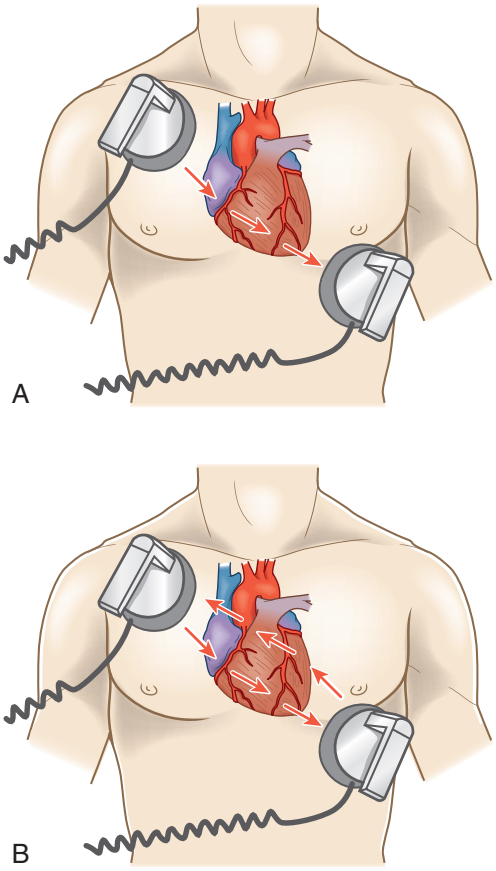

FIG. 36-20 Paddle placement and current flow in monophasic defibrillation **(A)** and biphasic defibrillation **(B).**

of myocardial cells will allow the SA node to resume the role of pacemaker.

Defibrillators deliver energy using a monophasic or biphasic waveform. Monophasic defibrillators deliver energy in one direction, and biphasic defibrillators deliver energy in two directions (Fig. 36-20). Biphasic defibrillators deliver successful shocks at lower energies and with fewer postshock ECG abnormalities than monophasic defibrillators.

The output of a defibrillator is measured in *joules*, or watts per second. The recommended energy for initial shocks in defibrillation depends on the type of defibrillator. Biphasic defibrillators deliver the first and any successive shocks using 120 to 200 joules. Recommendations for monophasic defibrillators include an initial shock at 360 joules. After the first shock, start CPR immediately beginning with chest compressions. (CPR is discussed in Appendix A of this book.)

Rapid defibrillation can be performed using a manual or automatic device (Fig. 36-21). Manual defibrillators require you to interpret heart rhythms, determine the need for a shock, and deliver a shock. An **automatic external defibrillator (AED)** can detect heart rhythms and advise the user to deliver a shock using hands-free defibrillator pads. Proficiency in use of the AED is part of the basic life support course for health care providers. You should be familiar with the operation of the type of defibrillator used in your clinical setting.

The following general steps are taken for defibrillation: (1) CPR should be in progress until the defibrillator is available; (2) turn the defibrillator on, and select the proper energy level;

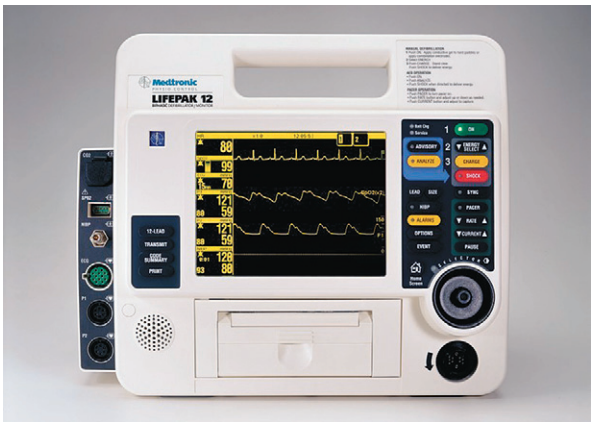

FIG. 36-21 LifePak contains a monitor, defibrillator, and transcutaneous pacemaker.

(3) check to see that the synchronizer switch is turned off (discussed below); (4) apply conductive materials (e.g., defibrillator gel pads) to the chest, one to the right of the sternum just below the clavicle, and the other to the left of the apex; (5) charge the defibrillator using the button on the defibrillator or the paddles; (6) position the paddles firmly on the chest wall over the conductive material (see Fig. 36-20); (7) call and look to see that everyone is "all clear" to ensure that personnel are not touching the patient or the bed at the time of discharge; and (8) deliver the charge by depressing buttons on both paddles simultaneously.

Hands-free, multifunction defibrillator pads are available and are placed on the chest as described above. Connect the cables from the pads to the defibrillator. Charge and discharge the defibrillator using buttons on the defibrillator. It is still essential to ensure that all personnel are clear before discharging the defibrillator.

Synchronized Cardioversion. *Synchronized cardioversion* is the therapy of choice for the patient with ventricular tachydysrhythmias (e.g., VT with a pulse) or supraventricular tachydysrhythmias (e.g., atrial fibrillation with a rapid ventricular response). A synchronized circuit in the defibrillator delivers a shock that is programmed to occur on the R wave of the QRS complex of the ECG. The synchronizer switch must be turned on when cardioversion is planned.

The procedure for synchronized cardioversion is the same as for defibrillation with the following exceptions. If synchronized cardioversion is done on a nonemergency basis (i.e., the patient is awake and hemodynamically stable), the patient is sedated (e.g., IV midazolam [Versed]) before the procedure. Strict attention to maintaining the patient's airway is critical. If a patient with supraventricular tachycardia or VT with a pulse becomes hemodynamically unstable, synchronized cardioversion should be performed as quickly as possible. Start the initial energy for synchronized cardioversion at 50 to 100 joules (biphasic defibrillator) and 100 joules (monophasic defibrillator), and increase if needed. If the patient becomes pulseless or the rhythm changes to VF, turn the synchronizer switch off and perform defibrillation.

SAFETY ALERT: Defibrillation and Cardioversion

- Check that the synchronizer switch is OFF when defibrillation is planned.
- Turn the synchronizer switch ON when cardioversion is planned.
- Be certain that personnel are "all clear" before discharging the device.

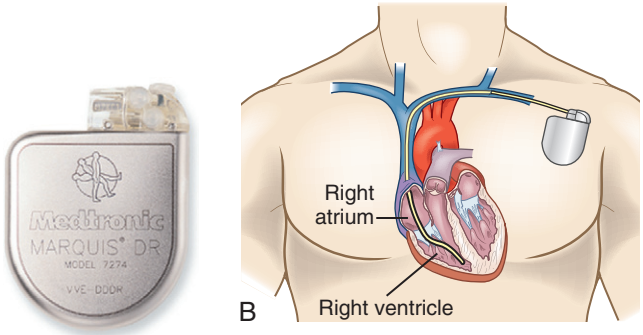

FIG. 36-22 **A,** The implantable cardioverter-defibrillator (ICD) pulse generator from Medtronic, Inc. **B,** The ICD is placed in a subcutaneous pocket over the pectoral muscle. A single-lead system is placed transvenously from the pulse generator to the endocardium. The single lead detects dysrhythmias and delivers an electric shock to the heart muscle.

Implantable Cardioverter-Defibrillator. The *implantable cardioverter-defibrillator* (ICD) is an important technology for patients who (1) have survived SCD, (2) have spontaneous sustained VT, (3) have syncope with inducible VT or VF during EPS, or (4) are at high risk for future life-threatening dysrhythmias (e.g., have cardiomyopathy). The use of ICDs has significantly decreased cardiac mortality rates in these patients.[11]

The ICD consists of a lead system placed via a subclavian vein to the endocardium. A battery-powered pulse generator is implanted subcutaneously, usually over the pectoral muscle on the patient's nondominant side. The pulse generator is similar in size to a pacemaker. Most systems are single-lead systems (Fig. 36-22). The ICD sensing system monitors the HR and rhythm and identifies VT or VF. After the sensing system detects a lethal dysrhythmia, the device delivers a 25-joule or less shock to the patient's heart. If the first shock is unsuccessful, the device recycles and can continue to deliver shocks.

In addition to defibrillation capabilities, ICDs are equipped with antitachycardia and antibradycardia pacemakers. These devices use algorithms that detect dysrhythmias and determine the appropriate response. They can initiate *overdrive pacing* of supraventricular tachycardia and VT, sparing the patient painful defibrillator shocks. They also provide backup pacing for bradydysrhythmias that may occur after defibrillation. Preprocedure and postprocedure nursing care of the patient undergoing ICD placement is similar to the care of a patient undergoing permanent pacemaker implantation (see p. 805).

Teaching the patient who is receiving an ICD and the caregiver is extremely important. Patients experience a variety of emotions, including fear of body image change, fear of recurrent dysrhythmias, expectation of pain with ICD discharge (described as a feeling of a blow to the chest), and anxiety about going home. Encourage patients and caregivers to participate in local or online ICD support groups[12] (*www.implantable.com*). Table 36-10 presents teaching guidelines for the patient with an ICD and the caregiver.

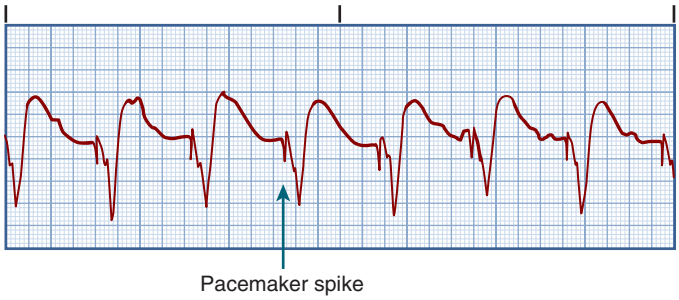

FIG. 36-23 Ventricular capture (depolarization) secondary to signal *(pacemaker spike)* from pacemaker lead in the right ventricle.

TABLE 36-10 PATIENT & CAREGIVER TEACHING GUIDE

Implantable Cardioverter-Defibrillator (ICD)

Include the following information in the teaching plan for a patient receiving an ICD and the patient's caregiver.

1. Follow up with cardiologist for routine checks of the function of the ICD.
2. Report any signs of infection at incision site (e.g., redness, swelling, drainage) or fever immediately.
3. Keep incision dry for 4 days after insertion or as instructed.
4. Avoid lifting arm on ICD side above shoulder until approved.
5. Discuss resuming sexual activity with your cardiologist. It is usually safe to resume sexual activity once your incision is healed.
6. Avoid driving until cleared by your cardiologist. This decision is usually based on the ongoing presence of dysrhythmias, the frequency of ICD firings, your overall health, and state laws regarding drivers with ICDs.
7. Avoid direct blows to ICD site.
8. Avoid large magnets and strong electromagnetic fields because these may interfere with the device.
9. You should not have a magnetic resonance imaging (MRI) scan unless the ICD is approved as MRI safe or there is a protocol in place for patient safety during the procedure.
10. Air travel is not restricted. Inform airport security of presence of ICD because it may set off the metal detector. If hand-held screening wand is used, it should not be placed directly over the ICD. Manufacturer information may vary regarding the effect of metal detectors on the function of the ICD.
11. Avoid standing near antitheft devices in doorways of stores and public buildings. You should walk through them at a normal pace.
12. If your ICD fires, call your cardiologist immediately.
13. If your ICD fires and you feel sick, contact the emergency medical services (EMS).
14. If your ICD fires more than once, contact EMS.
15. You should obtain and wear a Medic Alert ID or bracelet at all times.
16. Always carry the ICD identification card and a current list of your medications.
17. Consider joining an ICD support group (e.g., *www.icdsupportgroup.org*).
18. Caregivers should learn cardiopulmonary resuscitation (CPR).

Pacemakers

The artificial **cardiac pacemaker** is an electronic device used to pace the heart when the normal conduction pathway is damaged. The basic pacing circuit consists of a power source (battery-powered pulse generator) with programmable circuitry, one or more pacing leads, and the myocardium. The electrical signal (stimulus) travels from the pulse generator, through the leads, to the wall of the myocardium. The myocardium is "captured" and stimulated to contract (Fig. 36-23).

Current pacemakers are small, sophisticated, and physiologically precise. They pace the atrium and/or one or both of the ventricles. Most pacemakers are *demand pacemakers.* This means that they sense the heart's electrical activity and fire only when the HR drops below a preset rate. Demand pacemakers

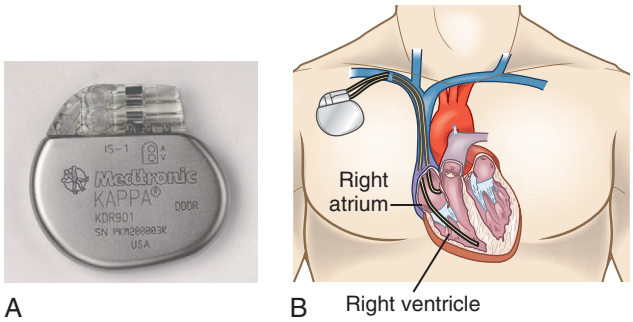

FIG. 36-24 **A,** A dual-chamber rate-responsive pacemaker from Medtronic, Inc., is designed to treat patients with chronic heart problems in which the heart beats too slowly to adequately support the body's circulation needs. **B,** Pacing leads in both the atrium and the ventricle enable a dual-chamber pacemaker to sense and pace in both heart chambers.

FIG. 36-25 Temporary external, dual-chamber demand pacemaker.

have two distinct features: (1) a sensing device that inhibits the pacemaker when the HR is adequate and (2) a pacing device that triggers the pacemaker when no QRS complexes occur within a preset time.[1,13]

In addition to antibradycardia pacing, devices now include antitachycardia and overdrive pacing. *Antitachycardia pacing* involves the delivery of a stimulus to the ventricle to end tachydysrhythmias (e.g., VT). Overdrive pacing involves pacing the atrium at rates of 200 to 500 impulses per minute in an attempt to terminate atrial tachycardias (e.g., atrial flutter with a rapid ventricular response). You can refer to texts on pacemaker therapy for more detailed information[13] and to eTable 36-1 for the Five Letter Pacemaker Code on the website for this chapter.

Permanent Pacemaker. A *permanent pacemaker* is implanted totally within the body (Fig. 36-24). The power source is placed subcutaneously, usually over the pectoral muscle on the patient's nondominant side. The pacing leads are placed transvenously to the right atrium and/or one or both ventricles and attached to the power source. Common reasons for insertion of a permanent pacemaker are found in Table 36-11.

Cardiac Resynchronization Therapy. *Cardiac resynchronization therapy* (CRT) is a pacing technique that resynchronizes the cardiac cycle by pacing both ventricles *(biventricular pacing)*. This promotes improvement in ventricular function (see Fig. 35-4). Most HF patients have intraventricular conduction delays causing abnormal ventricular contraction. This causes dyssynchrony between the right and left ventricles and results in reduced systolic function, pump inefficiency, and worsened HF. For patients with severe left ventricular dysfunction, CRT is combined with an ICD for maximum therapy.[14] (HF is discussed in Chapter 35.)

Temporary Pacemaker. A *temporary pacemaker* is one that has the power source outside the body (Fig. 36-25). There are three types of temporary pacemakers: transvenous, epicardial, and transcutaneous. Table 36-12 lists common reasons for temporary pacing.

A *transvenous pacemaker* consists of a lead or leads that are threaded transvenously to the right atrium and/or right ventricle and attached to the external power source (Fig. 36-26). Most temporary transvenous pacemakers are inserted in emergency departments and critical care units in emergent situations. They provide a bridge to insertion of a permanent pacemaker or until the underlying cause of the dysrhythmia is resolved.

Epicardial pacing involves attaching an atrial and ventricular pacing lead to the epicardium during heart surgery. The leads are passed through the chest wall and attached to the external power source. Epicardial pacing leads are placed prophylactically should any bradydysrhythmias or tachydysrhythmias occur in the early postoperative period.[8]

A *transcutaneous pacemaker* (TCP) is used to provide adequate HR and rhythm to the patient in an emergency situation. Placement of the TCP is a noninvasive, temporary procedure used until a transvenous pacemaker is inserted or until more definitive therapy is available.[8]

TABLE 36-11 INDICATIONS FOR PERMANENT PACEMAKERS

- Acquired AV block
- Second-degree AV block
- Third-degree AV block
- Atrial fibrillation with a slow ventricular response
- Bundle branch block
- Cardiomyopathy
  - Dilated
  - Hypertrophic
- Heart failure
- SA node dysfunction
- Tachydysrhythmias (e.g., ventricular tachycardia)

AV, Atrioventricular; *SA,* sinoatrial.

TABLE 36-12 INDICATIONS FOR TEMPORARY PACEMAKERS*

- Maintenance of adequate HR and rhythm during special circumstances such as surgery and postoperative recovery, during cardiac catheterization or coronary angioplasty, during drug therapy that may cause bradycardia, and before implantation of a permanent pacemaker
- As prophylaxis after open heart surgery
- Acute anterior MI with second- or third-degree AV block or bundle branch block
- Acute inferior MI with symptomatic bradycardia and AV block
- Electrophysiologic studies to evaluate patient with bradydysrhythmias and tachydysrhythmias

*List is not all-inclusive.
AV, Atrioventricular; *HR,* heart rate; *MI,* myocardial infarction.

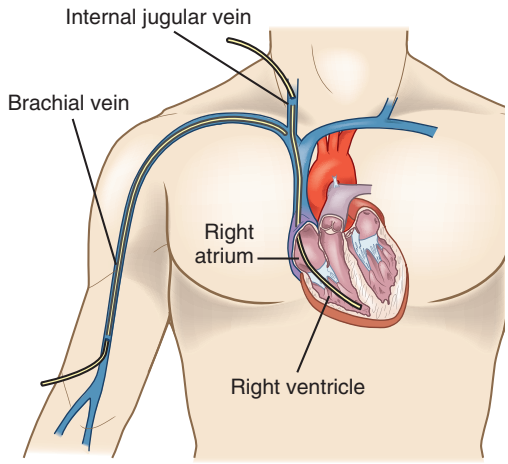

FIG. 36-26 Temporary transvenous pacemaker catheter insertion. A single lead is positioned in the right ventricle through the brachial, subclavian, jugular, or femoral vein.

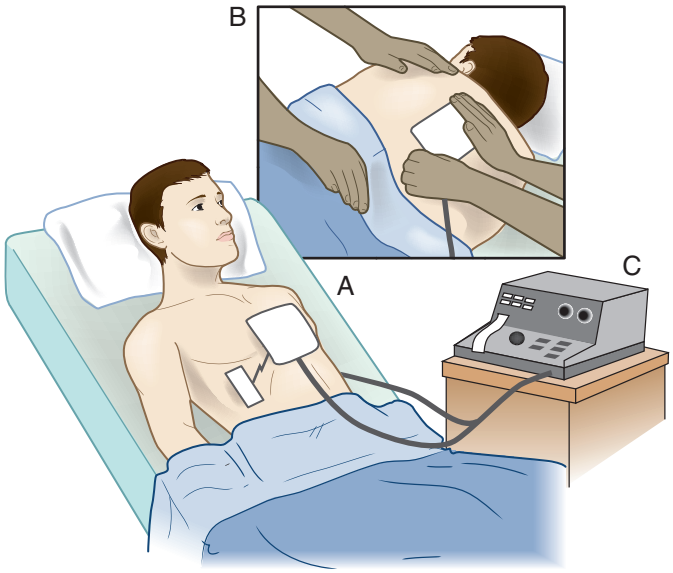

FIG. 36-27 Transcutaneous pacemaker. Pacing electrodes are placed on the patient's anterior *(A)* and posterior *(B)* chest walls and attached to an external pacing unit *(C)*.

The TCP consists of a power source and a rate- and voltage-control device that attaches to two large, multifunction electrode pads. Position one pad on the anterior part of the chest, usually on the V_4 lead position, and the other pad on the back between the spine and the left scapula at the level of the heart (Fig. 36-27). Always use the lowest current that results in a ventricular contraction (capture) to minimize patient discomfort.

Before initiating TCP therapy, it is important to tell the patient what to expect. Explain that the muscle contractions created by the pacemaker when the current passes through the chest wall are uncomfortable. Reassure the patient that the TCP is temporary and that it will be replaced by a transvenous pacemaker as soon as possible. Whenever possible, provide analgesia and/or sedation while the TCP is in use.

Monitoring of Patients With Pacemakers. Patients with temporary or permanent pacemakers are ECG monitored to evaluate the status of the pacemaker. Pacemaker malfunction primarily involves a failure to sense or a failure to capture. *Failure to sense* occurs when the pacemaker fails to recognize spontaneous atrial or ventricular activity, and it fires inappropriately. This can result in the pacemaker firing during the excitable period of the cardiac cycle, resulting in VT. Failure to sense is caused by pacer lead damage, battery failure, sensing set too high, or dislodgment of the electrode. *Failure to capture* occurs when the electrical charge to the myocardium is insufficient to produce atrial or ventricular contraction. This can result in serious bradycardia or asystole. Failure to capture is caused by pacer lead damage, battery failure, dislodgment of the electrode, electrical charge set too low, or fibrosis at the electrode tip.

Complications of invasive temporary (i.e., transvenous) or permanent pacemaker insertion include infection and hematoma formation at the insertion site, pneumothorax, failure to sense or capture, perforation of the atrial or ventricular septum by the pacing lead, and appearance of "end-of-life" battery power on testing the pacemaker. Several measures can prevent or assess for complications. These include prophylactic IV antibiotic therapy before and after insertion, postinsertion chest x-ray to check lead placement and to rule out a pneumothorax, careful observation of insertion site, and continuous ECG monitoring of the patient's rhythm.

After the pacemaker has been inserted, the patient can be out of bed once stable. Have the patient limit arm and shoulder activity on the operative side to prevent dislodging the newly implanted pacing leads. Observe the insertion site for signs of bleeding, and check that the incision is intact. Note any temperature elevation or pain at the insertion site and treat as ordered. Most patients are discharged the next day if stable.

Provide teaching in addition to observing for complications after pacemaker insertion. The patient with a newly implanted pacemaker and the caregiver may have questions about activity restrictions and fears concerning body image after the procedure. The goals of pacemaker therapy include enhancing physiologic functioning and quality of life. Emphasize this to the patient and the caregiver, and provide specific advice on activity restrictions. Table 36-13 outlines patient and caregiver teaching for the patient with a pacemaker.

After discharge, patients need to check pacemaker function on a regular basis. This can include outpatient visits to a pacemaker clinic or home monitoring using telephone transmitter devices. Another method to evaluate pacemaker performance is noninvasive program stimulation. This procedure is done on an outpatient basis in the EPS laboratory.

Radiofrequency Catheter Ablation Therapy

Radiofrequency catheter ablation therapy uses electrical energy to "burn" or ablate areas of the conduction system as definitive treatment of tachydysrhythmias. Ablation therapy is done after EPS has identified the source of the dysrhythmia. An electrode-tipped ablation catheter ablates accessory pathways or ectopic sites in the atria, the AV node, and the ventricles. Catheter ablation is considered the nonpharmacologic treatment of choice for atrial dysrhythmias resulting in rapid ventricular rates and AV nodal reentrant tachycardia refractory to drug therapy.[7,9]

The ablation procedure is successful with a low complication rate. Care of the patient after ablation therapy is similar to that of a patient undergoing cardiac catheterization (see Chapter 32 and Table 32-6).

TABLE 36-13 PATIENT & CAREGIVER TEACHING GUIDE

Pacemaker

Include the following information in the teaching plan for a patient with a pacemaker and the patient's caregiver.

1. Maintain follow-up care with your cardiologist to begin regular pacemaker function checks.
2. Report any signs of infection at incision site (e.g., redness, swelling, drainage) or fever to your cardiologist immediately.
3. Keep incision dry for 4 days after implantation, or as ordered.
4. Avoid lifting arm on pacemaker side above shoulder until approved by your cardiologist.
5. Avoid direct blows to pacemaker site.
6. Avoid close proximity to high-output electric generators, since these can interfere with the function of the pacemaker.
7. You should not have a magnetic resonance imaging (MRI) scan unless the pacemaker is approved as MRI safe or there is a protocol in place for patient safety during the procedure.
8. Microwave ovens are safe to use and do not interfere with pacemaker function.
9. Avoid standing near antitheft devices in doorways of department stores and public libraries. You should walk through them at a normal pace.
10. Air travel is not restricted. Inform airport security of presence of pacemaker because it may set off the metal detector. If hand-held screening wand is used, it should not be placed directly over the pacemaker. Manufacturer information may vary regarding the effect of metal detectors on the function of the pacemaker.
11. Monitor pulse and inform cardiologist if it drops below predetermined rate.
12. Carry pacemaker information card and a current list of your medications at all times.
13. Obtain and wear a Medic Alert ID or bracelet at all times.

ECG CHANGES ASSOCIATED WITH ACUTE CORONARY SYNDROME

The 12-lead ECG is a major diagnostic tool used to evaluate patients with ACS. ECG changes that occur with ACS direct many treatment decisions. The ECG changes are in response to ischemia, injury, or infarction (necrosis) of heart cells. The leads facing the area of involvement demonstrate the definitive ECG changes (Fig. 36-28). The leads facing opposite the area involved in ACS often demonstrate reciprocal (opposite) ECG changes. In addition, the pattern of ECG changes among the 12 leads provides information on the coronary artery involved in ACS (Table 36-14).

Ischemia

Typical ECG changes that are seen in myocardial ischemia include ST segment depression and/or T wave inversion (Fig. 36-29, *A*). ST segment depression is significant if it is at least 1 mm (one small box) below the isoelectric line in at least two contiguous (neighboring) leads (see Fig. 36-5). The isoelectric line is flat and represents those normal times in the cardiac cycle when the ECG is not recording any electrical activity in the heart. These times are as follows: (1) from the end of the P wave to the start of the QRS complex, (2) during the entire ST segment, and (3) from the end of the T wave to the start of the next P wave (see Fig. 36-9). Depression in the ST segment and/or T wave inversion occurs in response to an inadequate supply of blood and oxygen, which causes an electrical disturbance in the myocardial cells.[6,7] Once the patient is treated (adequate blood flow is restored), the ECG changes resolve, and the ECG returns to the patient's baseline. (See Chapter 34 for a complete discussion of ACS.)

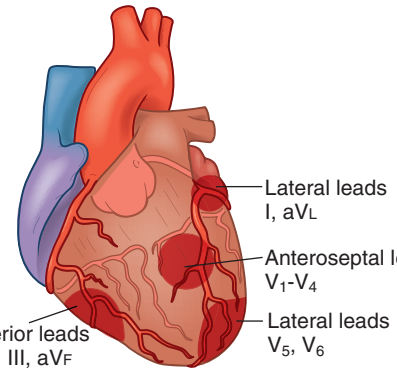

FIG. 36-28 Definitive ECG changes occur in leads that face the area of ischemia, injury, or infarction. Reciprocal changes may occur in leads facing opposite the area of ischemia, injury, or infarction.

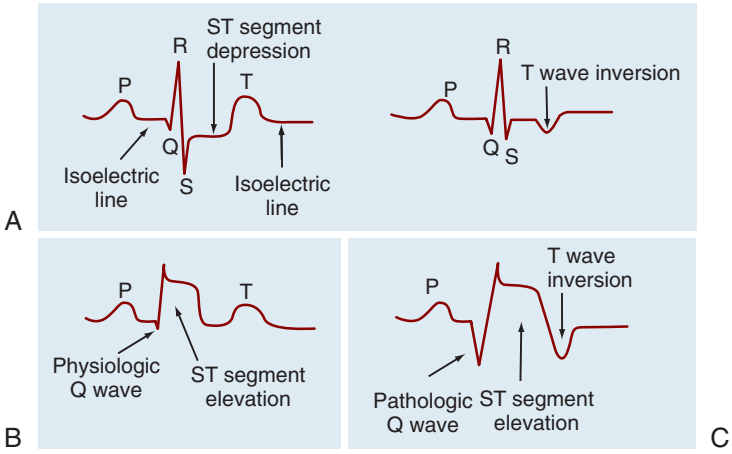

FIG. 36-29 ST segment, T wave, and Q wave changes associated with myocardial ischemia **(A),** injury **(B),** and infarction **(C).**

TABLE 36-14 ECG EVIDENCE IN ACUTE CORONARY SYNDROME

Left Ventricle Involvement	ECG Evidence: Leads Facing Area	ECG Evidence: Leads Opposite Area (Reciprocal Changes)	Associated Coronary Artery
Septal wall	V_1, V_2	II, III, aVF	Left anterior descending
Anterior wall	V_2-V_4	II, III, aVF	Left anterior descending
Lateral wall, low	V_5, V_6	II, III, aVF	Left anterior descending or circumflex
Lateral wall, high	I, aVL	II, III, aVF	Circumflex
Inferior wall	II, III, aVF	I, aVL, V_5, V_6	Right coronary artery, posterior descending coronary artery

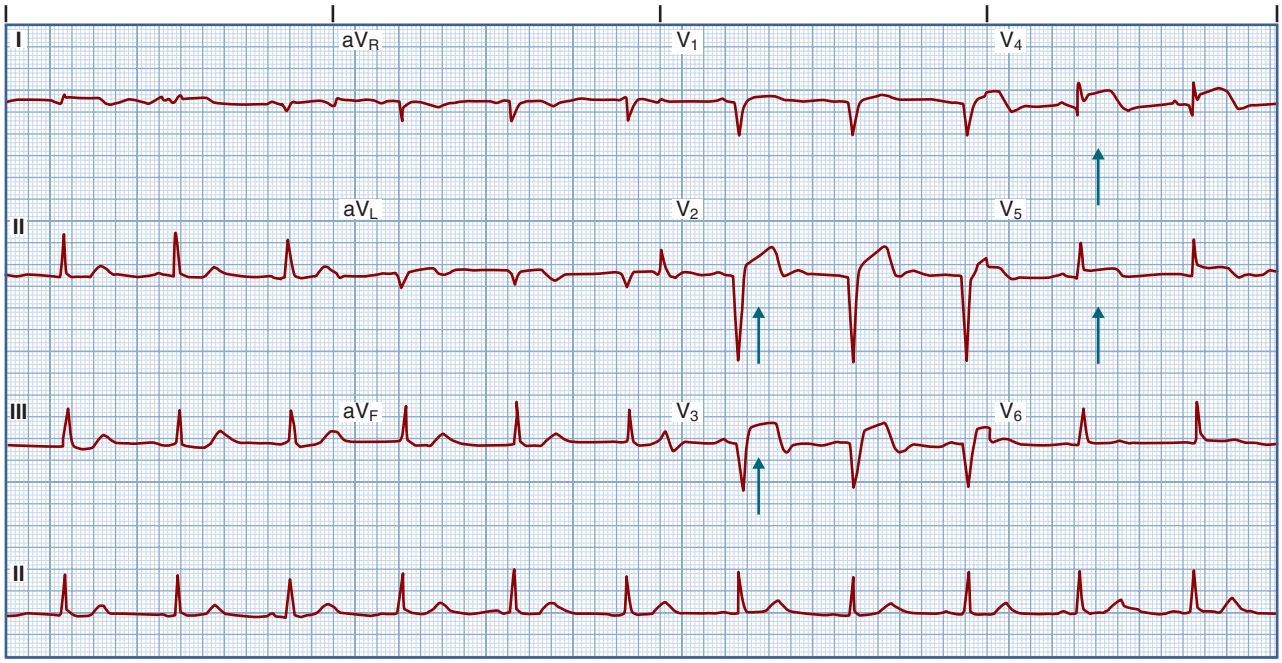

FIG. 36-30 ECG findings with anteroseptal lateral wall myocardial infarction. Normally, leads I, aVL, and V_1 to V_3 have a positive R wave. Note the pathologic Q waves in these leads and the ST segment elevation in leads V_2 to V_5 *(arrows)*.

Injury and Infarction

Myocardial injury represents a worsening stage of ischemia that is potentially reversible but may evolve to MI. The typical ECG change seen during injury is ST segment elevation. ST segment elevation is significant if it is 1 mm or more above the isoelectric line in at least two contiguous leads (Fig. 36-29, *B*). If treatment is prompt and effective, it is possible to restore oxygen to the myocardium and avoid or limit infarction. The absence of serum cardiac markers confirms this.

In addition to ST segment elevation, a pathologic Q wave may be seen on the ECG in patients with infarction (Fig. 36-29, *C*). A physiologic Q wave is the first negative deflection (wave) following the P wave. It is normally very short and narrow (see Fig. 36-9 and Table 36-2). A pathologic Q wave that develops during MI is wide (greater than 0.03 second in duration) and deep (greater than or equal to 25% of the height of the R wave).[1,7] This is referred to as a *Q wave MI.* The pathologic Q wave may be present on the ECG indefinitely.

T wave inversion related to MI occurs within hours following the event and may persist for months. The ECG changes seen in injury and MI reflect electrical disturbances in the myocardial cells caused by a prolonged lack of blood and oxygen leading to necrosis (Fig. 36-30).

Patient Monitoring

Monitoring guidelines for patients who are suspected of having ACS include continuous, multilead ECG and ST segment monitoring.[3] The leads selected for monitoring should minimally include the leads that reflect the area of ischemia, injury, or infarction.

SYNCOPE

Syncope, a brief lapse in consciousness accompanied by a loss in postural tone (fainting), is a common diagnosis of patients coming to the emergency department. The causes of syncope can be cardiovascular or noncardiovascular. The most common cause of syncope is cardioneurogenic syncope, or "vasovagal" syncope (e.g., carotid sinus sensitivity). Other cardiovascular causes relate to dysrhythmias (e.g., tachycardias, bradycardias), prosthetic valve malfunction, pulmonary emboli, and HF. Noncardiovascular causes vary and include stress, hypoglycemia, dehydration, stroke, and seizure.[14]

A diagnostic workup for a patient with syncope from a suspected cardiac cause begins with ruling out structural and ischemic heart disease. This is done with echocardiography and stress testing. In the older patient, who is more likely to have structural and ischemic heart disease, EPS is used to diagnose atrial and ventricular tachydysrhythmias and conduction disturbances causing bradydysrhythmias, all of which can cause syncope. These problems can be treated with antidysrhythmia drug therapy, pacemakers, ICDs, and/or catheter ablation therapy.

In patients without structural heart disease or in whom EPS testing is not diagnostic, the *head-up tilt-test* may be performed. Normally, an upright position results in gravity displacing 300 to 800 mL of blood to the lower extremities. Specialized nerve fibers called mechanoreceptors are located throughout the vascular system. These respond to the increased blood volume by starting a reflex increase in sympathetic stimulation and decrease in parasympathetic output. The end results are a slight increase in HR and diastolic BP, and a slight decrease in systolic BP.[15]

In cardioneurogenic syncope, the increase in venous pooling that occurs in the upright position reduces venous return to the heart. This results in a sudden, compensatory increase in ventricular contraction. This is mistaken by the brain as a hypertensive state, and consequently sympathetic stimulation is withdrawn. This produces a paradoxic vasodilation and bradycardia (vasovagal response). The end results are bradycardia, hypotension, cerebral hypoperfusion, and syncope.

In the head-up tilt-test the patient is placed on a table supported by a belt across the torso and feet. Baseline ECG, BP, and HR are obtained in the horizontal position. Next, the table is tilted 60 to 80 degrees and the patient is kept in this upright position for 20 to 60 minutes. ECG and HR are recorded continuously and BP is measured every 3 minutes throughout the test.

If the patient's BP and HR responses are abnormal and clinical symptoms are reproduced (e.g., faintness), the test is considered positive. If after 30 minutes there is no response, the table is returned to the horizontal position and an IV infusion of low-dose isoproterenol may be started in an attempt to provoke a response.

Additional diagnostic tests for syncope can include various recording devices (e.g., Holter monitor or event monitor/loop recorder, which are discussed in Chapter 32 and Table 32-6), blood volume determination, hemodynamic testing, and autonomic reflex testing. About 30% of those who have one episode of syncope experience a recurrence. The underlying cause of syncope and the patient's age and co-morbidities affect the patient's treatment and prognosis.[15]

CASE STUDY

Dysrhythmia

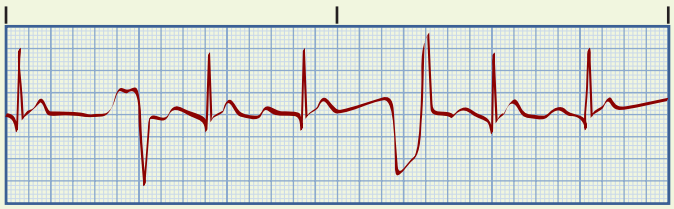
iStockphoto/Thinkstock

Patient Profile

J.M., a 68-year-old retired white postal worker, was admitted to the telemetry unit with a diagnosis of acute decompensated heart failure (HF). He experienced a cardiac arrest (pulseless ventricular tachycardia [VT]) and was successfully defibrillated after one shock. He is transferred to the cardiac care unit. J.M. is awake but lethargic, and responds appropriately to questions.

Subjective Data

- History of hypertension, coronary artery disease, two MIs, and chronic HF
- Reports shortness of breath at rest and even in an upright position



Objective Data

Physical Examination

- Appears weak, anxious
- BP 102/60 mm Hg, pulse 70/min, respirations 26/min
- Lungs: bilateral coarse crackles in the bases
- Heart: S_3 gallop at apex

Diagnostic Studies

- Continuous ECG monitoring

- Echocardiogram: severe left ventricular dysfunction with ejection fraction of 25%
- Serum potassium: 2.9 mEq/L (2.9 mmol/L)
- Serum cardiac markers: negative
- Serum b-type natriuretic peptide (BNP): 1852 pg/mL

Collaborative Care

- Amiodarone (Cordarone) infusion
- Scheduled for electrophysiologic study (EPS)

Discussion Questions

1. Why is J.M. at risk for sudden cardiac death?
2. Explain the rationale for using amiodarone after cardiac arrest.
3. What methods are used to assess the effectiveness of the antidysrhythmia therapy?
4. Interpret the rhythm strip and explain the significance of the other diagnostic studies.
5. Why would J.M. be a candidate for CRT and an ICD?
6. ***Priority Decision:*** Based on the assessment data provided, what are the priority nursing diagnoses?
7. ***Priority Decision:*** Based on these nursing diagnoses, what are the priority nursing interventions for J.M.?
8. ***Delegation Decision:*** Which tasks could be delegated to unlicensed assistive personnel (UAP)?
9. ***Evidence-Based Practice***: Once J.M. is stable, he is scheduled for the insertion of a CRT/ICD. On your rounds, he asks you why he needs two devices.

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient admitted with ACS has continuous ECG monitoring. An examination of the rhythm strip reveals the following characteristics: atrial rate 74 beats/min and regular; ventricular rate 62 beats/min and irregular; P wave normal shape; PR interval lengthens progressively until a P wave is not conducted; QRS normal shape. The priority nursing intervention would be to
   a. perform synchronized cardioversion.
   b. administer epinephrine 1 mg IV push.
   c. observe for symptoms of hypotension or angina.
   d. apply transcutaneous pacemaker pads on the patient.

2. The nurse is monitoring the ECG of a patient admitted with ACS. Which ECG characteristics would be most suggestive of myocardial ischemia?
   a. Sinus rhythm with a pathologic Q wave
   b. Sinus rhythm with an elevated ST segment
   c. Sinus rhythm with a depressed ST segment
   d. Sinus rhythm with premature atrial contractions

3. The ECG monitor of a patient in the cardiac care unit after an MI indicates ventricular bigeminy with a rate of 50 beats/min. The nurse would anticipate
   a. performing defibrillation.
   b. treating with IV amiodarone.
   c. inserting a temporary transvenous pacemaker.
   d. assessing the patient's response to the dysrhythmia.
4. The nurse prepares a patient for synchronized cardioversion knowing that cardioversion differs from defibrillation in that
   a. defibrillation requires a lower dose of electrical energy.
   b. cardioversion is indicated to treat atrial bradydysrhythmias.
   c. defibrillation is synchronized to deliver a shock during the QRS complex.
   d. patients should be sedated if cardioversion is done on a non-emergency basis.
5. Which patient teaching points should the nurse include when providing discharge instructions to a patient with a new permanent pacemaker and the caregiver *(select all that apply)?*
   a. Avoid or limit air travel.
   b. Take and record a daily pulse rate.
   c. Obtain and wear a Medic Alert ID or bracelet at all times.
   d. Avoid lifting arm on the side of the pacemaker above shoulder.
   e. Avoid microwave ovens because they interfere with pacemaker function.
6. Important teaching for the patient scheduled for a radiofrequency catheter ablation procedure includes explaining that
   a. ventricular bradycardia may be induced and treated during the procedure.
   b. a catheter will be placed in both femoral arteries to allow double-catheter use.
   c. the procedure will destroy areas of the conduction system that are causing rapid heart rhythms.
   d. a general anesthetic will be given to prevent the awareness of any "sudden cardiac death" experiences.

1. c, 2. c, 3. d, 4. d, 5. b, c, d, 6. c

LEARNING OUTCOMES

1. Differentiate the etiology, pathophysiology, and clinical manifestations of infective endocarditis and pericarditis.
2. Describe the collaborative care and nursing management of the patient with infective endocarditis and pericarditis.
3. Describe the etiology, pathophysiology, and clinical manifestations of myocarditis.
4. Describe the collaborative care and nursing management of the patient with myocarditis.
5. Differentiate the etiology, pathophysiology, and clinical manifestations of rheumatic fever and rheumatic heart disease.
6. Describe the collaborative care and nursing management of the patient with rheumatic fever and rheumatic heart disease.
7. Relate the pathophysiology to the clinical manifestations and diagnostic studies for the various types of valvular heart disease.
8. Describe the collaborative care and nursing management of the patient with valvular heart disease.
9. Relate the pathophysiology to the clinical manifestations and diagnostic studies for the different types of cardiomyopathy.
10. Compare the nursing and collaborative management of patients with different types of cardiomyopathy.

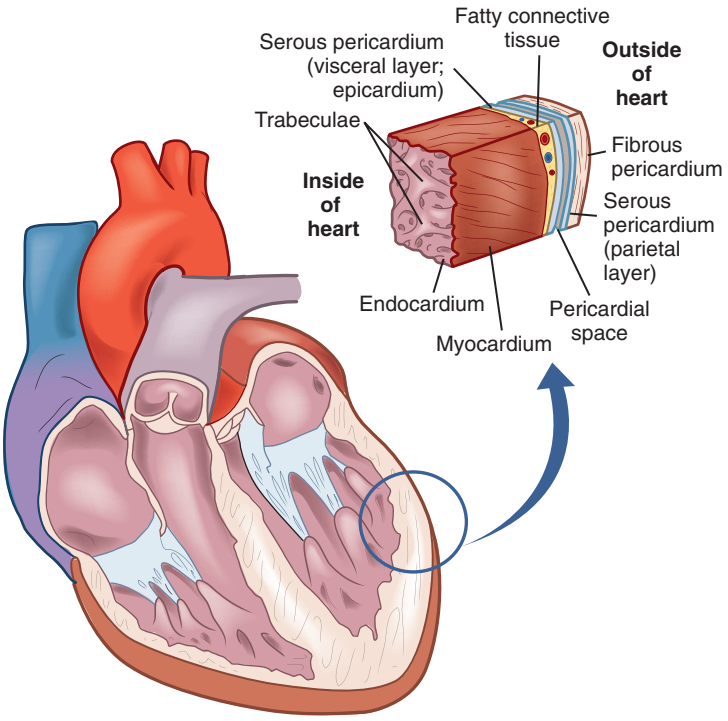

FIG. 37-1 Layers of the heart muscle and pericardium. The section of the heart wall shows the fibrous pericardium, the parietal and visceral layers of the serous pericardium (with the pericardial sac between them), the myocardium, and the endocardium.

This chapter describes the pathophysiology and management of patients experiencing select inflammatory and structural heart disorders. In addition, the nursing care required to manage the needs of these patients is presented.

INFLAMMATORY DISORDERS OF HEART

INFECTIVE ENDOCARDITIS

Infective endocarditis (IE) is an infection of the endocardial layer of the heart. The *endocardium* is the innermost layer of the heart (Fig. 37-1) and heart valves. Therefore IE affects the valves. Treatment of IE with antibiotic therapy has improved the prognosis of this disease. Though relatively uncommon, an estimated 10,000 to 15,000 new cases of IE are diagnosed in the United States each year.[1]

Classification

IE can be classified as subacute or acute. The *subacute form* typically affects those with preexisting valve disease and has a clinical course that may extend over months. In contrast, the *acute form* typically affects those with healthy valves and manifests as a rapidly progressive illness. IE can also be classified based on the cause (e.g., IV drug abuse IE [IVDA IE], fungal endocarditis) or site of involvement (e.g., prosthetic valve endocarditis [PVE]).

Etiology and Pathophysiology

The most common causative organisms of IE, *Staphylococcus aureus* and *Streptococcus viridans,* are bacterial. Other possible pathogens include fungi and viruses.[2] IE occurs when blood turbulence within the heart allows the causative organism to infect previously damaged valves or other endothelial surfaces. This can occur in individuals with a variety of underlying cardiac and noncardiac conditions (Table 37-1).

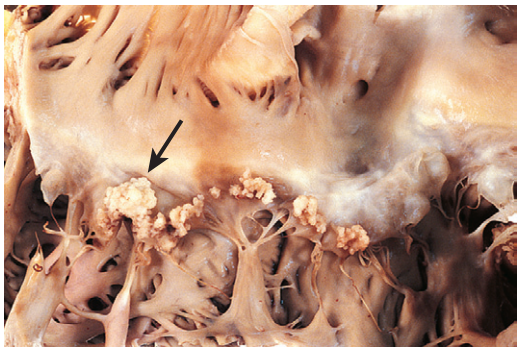

FIG. 37-2 Bacterial endocarditis of the mitral valve. The valve is covered with large, irregular vegetations *(arrow).*

TABLE 37-1 RISK FACTORS FOR ENDOCARDITIS*

Cardiac Conditions
- Prior endocarditis
- Prosthetic heart valves
- Acquired valve disease (e.g., mitral valve prolapse with regurgitation, calcified aortic stenosis)
- Cardiac lesions (e.g., ventricular septal defect, asymmetric septal hypertrophy)
- Rheumatic heart disease (e.g., mitral valve regurgitation)
- Congenital heart disease
- Pacemakers
- Marfan's syndrome
- Cardiomyopathy

Noncardiac Conditions
- Hospital-acquired bacteremia
- IV drug abuse

Procedure-Associated Risks
- Intravascular devices (e.g., pulmonary artery catheters)
- Procedures listed in Table 37-2

*List is not all-inclusive.

Vegetations, the primary lesions of IE, consist of fibrin, leukocytes, platelets, and microbes that stick to the valve surface or endocardium (Fig. 37-2). The loss of parts of these fragile vegetations into the circulation results in *emboli.* As many as 50% of patients with IE experience systemic embolization. This occurs from left-sided heart vegetation moving to various organs (e.g., brain, kidneys, spleen) and to the extremities, causing limb infarction. Right-sided heart lesions move to the lungs, resulting in pulmonary emboli.

The infection may spread locally and damage the valves or their supporting structures. This causes dysrhythmias, valve dysfunction, and eventual invasion of the myocardium, leading to heart failure (HF), sepsis, and heart block (Fig. 37-3).

At one time rheumatic heart disease was the most common cause of IE. However, now it accounts for less than 20% of cases. The main contributing factors to IE include (1) aging (more than 50% of older people have aortic stenosis [AS]), (2) IVDA, (3) use of prosthetic valves, (4) use of intravascular devices resulting in health care–associated infections (e.g., methicillin-resistant *S. aureus* [MRSA]), and (5) renal dialysis.[3]

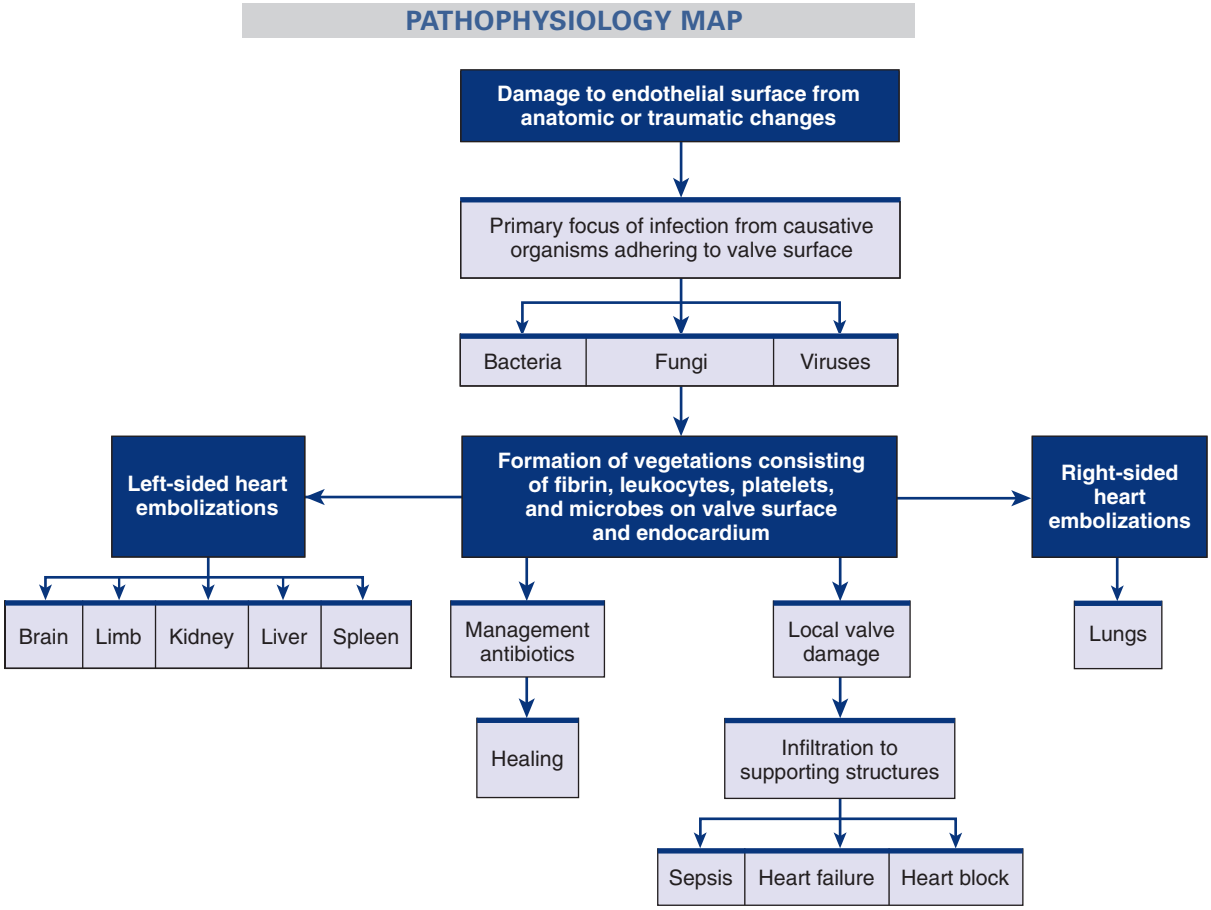

FIG. 37-3 Pathogenesis of infective endocarditis.

Clinical Manifestations

The clinical manifestations of IE are nonspecific and can involve multiple organ systems. Low-grade fever occurs in more than 90% of patients. Other nonspecific manifestations include chills, weakness, malaise, fatigue, and anorexia. Arthralgias, myalgias, back pain, abdominal discomfort, weight loss, headache, and clubbing of fingers may occur in subacute forms of endocarditis.

Vascular manifestations of IE include *splinter hemorrhages* (black longitudinal streaks) that may occur in the nail beds. Petechiae may result from fragmentation and microembolization of vegetative lesions. They can occur in the conjunctivae, lips, buccal mucosa, and palate and over the ankles, feet, and antecubital and popliteal areas. *Osler's nodes* (painful, tender, red or purple, pea-size lesions) may be found on the fingertips or toes. *Janeway's lesions* (flat, painless, small, red spots) may be seen on the palms and soles. Funduscopic examination may reveal hemorrhagic retinal lesions called *Roth's spots.*

The onset of a new or changing murmur is noted in most patients with IE. The aortic and mitral valves are most often affected. Murmurs are usually absent in tricuspid endocarditis because right-sided heart sounds are too low to be heard. HF occurs in up to 80% of patients with aortic valve endocarditis and in approximately 50% of patients with mitral valve endocarditis.[4]

Clinical manifestations secondary to embolization may be present in various body organs. Embolization to the spleen may cause sharp, left upper quadrant pain and splenomegaly, local tenderness, and abdominal rigidity. Embolization to the kidneys may cause flank pain, hematuria, and renal failure. Emboli may lodge in small peripheral blood vessels of the arms and legs and may cause ischemia and gangrene. Embolization to the brain may cause neurologic damage resulting in hemiplegia, ataxia, aphasia, visual changes, and change in the level of consciousness. Pulmonary emboli may occur in right-sided endocarditis and cause dyspnea, chest pain, hemoptysis, and respiratory arrest.

Diagnostic Studies

The patient's recent health history is important in assessing IE. Ask patients if they have had any recent (within the past 3 to 6 months) dental, urologic, surgical, or gynecologic procedures, including normal or abnormal obstetric delivery. Document any previous history of IVDA, heart disease, recent cardiac catheterization, cardiac surgery, intravascular device placement, renal dialysis, or infections (e.g., skin, respiratory, urinary tract).

Two blood cultures drawn 30 minutes apart from two different sites will be positive in more than 90% of patients. Culture-negative endocarditis is often associated with antibiotic usage within the previous 2 weeks, or results from a pathogen not easily detected by standard culture procedures. Negative cultures should be kept for 3 weeks if the clinical diagnosis remains endocarditis because of the possibility of slow-growing organisms. A mild leukocytosis occurs in acute IE (uncommon in subacute). The erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels may also be elevated.

Major criteria to diagnose IE include at least two of the following: positive blood cultures, new or changed heart murmur, or intracardiac mass or vegetation noted on echocardiography.[5] Echocardiography is valuable in the diagnostic workup for a patient with IE when the blood cultures are negative, or for the patient who is a surgical candidate and has an active infection. Transesophageal echocardiogram and two- or three-dimensional (2-D or 3-D) transthoracic echocardiograms can detect vegetations on the heart valves.[6]

A chest x-ray is done to detect *cardiomegaly* (an enlarged heart). An electrocardiogram (ECG) may show first- or second-degree atrioventricular (AV) block. Heart block occurs because the cardiac valves lie close to conductive tissue, especially the AV node. Cardiac catheterization may be used to evaluate valve functioning and to assess the coronary arteries when surgical intervention is being considered.[7]

Collaborative Care

Prophylactic Treatment. The situations and conditions requiring antibiotic prophylaxis are presented in Table 37-2.

Drug Therapy. Accurate identification of the infecting organism is the key to successful treatment of IE. Long-term treatment is necessary to kill dormant bacteria within the valvular vegetations. Complete elimination of the organism generally takes weeks, and relapses are common.

Initially, patients are hospitalized and IV antibiotic therapy, based on blood cultures, is started. The effectiveness of therapy is assessed with subsequent blood cultures. Cultures that remain positive indicate inadequate or inappropriate selection of antibiotic, aortic root or myocardial abscess, or the wrong diagnosis (e.g., an infection elsewhere).

Fungal endocarditis and PVE respond poorly to antibiotic therapy alone. Early valve replacement followed by prolonged (6 weeks or more) antibiotics is recommended in these situations. Valve replacement (discussed later in this chapter) has become an important adjunct procedure in the management of IE.

Fever may persist for several days after treatment has been started and can be treated with aspirin, acetaminophen (Tylenol), ibuprofen (Motrin), fluids, and rest. Complete bed rest is usually not indicated unless the temperature remains elevated or there are signs of HF. Endocarditis coupled with HF responds poorly to drug therapy and valve replacement and is often life threatening.

TABLE 37-2 ANTIBIOTIC PROPHYLAXIS TO PREVENT ENDOCARDITIS

Target Groups for Prophylactic Antibiotics

People with the following heart conditions should receive prophylactic antibiotics when they have the conditions or procedures listed below.

- Prosthetic heart valve or prosthetic material used to repair heart valve
- Previous history of infectious endocarditis
- Congenital heart disease (CHD)*
  - Unrepaired cyanotic CHD (including palliative shunts and conduits)
  - Repaired congenital heart defect with prosthetic material or device for 6 mo after the procedure
  - Repaired CHD with residual defects at the site or adjacent to the site of prosthetic patch or prosthetic device
- Cardiac transplantation recipients who develop heart valve disease

Conditions or Procedures Requiring Antibiotic Prophylaxis

When the target groups have the following conditions or procedures, they need prophylactic antibiotics.

- Oral
  - Dental manipulation involving the gums or roots of the teeth
  - Dental manipulation involving puncture of the oral mucosa
  - Dental extractions or implants
  - Prophylactic teeth cleaning with expected bleeding
- Respiratory
  - Respiratory tract incisions (e.g., biopsy)
  - Tonsillectomy and adenoidectomy
- Gastrointestinal and genitourinary
  - Wound infection
  - Urinary tract infection

*Except for the conditions listed above, prophylaxis is no longer recommended for any form of CHD.

Source: Habib G, Hoen B, Tornos P, et al: Guidelines on the prevention, diagnosis and treatment of infective endocarditis (new version 2009): the Task Force on the Prevention, Diagnosis, and Treatment of Infective Endocarditis of the European Society of Cardiology (ESC), *Eur Heart J* 30:2369, 2009.

NURSING MANAGEMENT INFECTIVE ENDOCARDITIS

NURSING ASSESSMENT

Subjective and objective data that you should obtain from a patient with IE are presented in Table 37-3. Assess vital signs together with heart sounds to detect a murmur, a change in a preexisting murmur, and extra sounds (e.g., S_3).

Arthralgia, which is common in IE, may involve multiple joints and be accompanied by myalgias. Assess the patient for joint tenderness, decreased range of motion (ROM), and muscle tenderness. Examine the patient for petechiae, splinter hemorrhages, and Osler's nodes. Complete a general systems assessment to determine any hemodynamic or embolic complications.

NURSING DIAGNOSES

Nursing diagnoses for the patient with IE may include, but are not limited to, the following:

- Decreased cardiac output *related to* altered heart rhythm, valvular insufficiency, and fluid overload
- Activity intolerance *related to* generalized weakness, arthralgia, and alteration in oxygen transport secondary to valvular dysfunction

Additional information on nursing diagnoses is presented in eNursing Care Plan 37-1 available on the website for this chapter.

PLANNING

The overall goals for the patient with IE include (1) normal or baseline heart function, (2) performance of activities of daily living (ADLs) without fatigue, and (3) knowledge of the therapeutic regimen to prevent recurrence of endocarditis.

NURSING IMPLEMENTATION

HEALTH PROMOTION. The incidence of IE can be decreased by identifying individuals who are at risk for the disease (see Tables 37-1 and 37-2). Assessment of the patient's history and an understanding of the disease process are crucial for planning and implementing appropriate health promotion strategies.

Teaching the patient at high risk for IE helps reduce the incidence and recurrence of the disease. Teaching is crucial for the patient's understanding of and adherence to the treatment

TABLE 37-3 NURSING ASSESSMENT

Infective Endocarditis

Subjective Data

Important Health Information

Past health history: Valvular, congenital, or syphilitic cardiac disease, including valve repair or replacement; previous endocarditis, childbirth, staphylococcal or streptococcal infections, hospital-acquired bacteremia

Medications: Immunosuppressive therapy

Surgery or other treatments: Recent obstetric or gynecologic procedures; invasive techniques, including catheterization, cystoscopy, intravascular procedures; recent dental or surgical procedures; GI procedures (e.g., endoscopy)

Functional Health Patterns

Health perception–health management: IV drug abuse, alcohol abuse; malaise

Nutritional-metabolic: Weight gain or loss; anorexia; chills, diaphoresis

Elimination: Bloody urine

Activity-exercise: Exercise intolerance, generalized weakness, fatigue; cough, dyspnea on exertion, orthopnea; palpitations

Sleep-rest: Night sweats

Cognitive-perceptual: Chest, back, or abdominal pain; headache; joint tenderness, muscle tenderness

Objective Data

General

Fever

Integumentary

Osler's nodes on extremities; splinter hemorrhages under nail beds; Janeway's lesions on palms and soles; petechiae of skin, mucous membranes, or conjunctivae; purpura; peripheral edema, finger clubbing

Respiratory

Tachypnea, crackles

Cardiovascular

Dysrhythmia, tachycardia, new murmurs, S_3, S_4; retinal hemorrhages

Possible Diagnostic Findings

Leukocytosis, anemia, ↑ ESR, ↑ CRP and cardiac enzymes; positive blood cultures; hematuria; echocardiogram showing chamber enlargement, valvular dysfunction, and vegetations; chest x-ray showing cardiomegaly and pulmonary infiltrates; ECG demonstrating ischemia and conduction defects; signs of systemic embolization or pulmonary embolism

CRP, C-reactive protein; *ESR*, erythrocyte sedimentation rate.

regimen. Tell the patient to avoid people with infection, especially upper respiratory tract infection, and to report cold, flu, and cough symptoms. Stress the importance of avoiding excessive fatigue and the need to plan rest periods before and after activity. Good oral hygiene, including daily care and regular dental visits, is also important. Instruct the patient to inform health care providers performing certain invasive procedures of the history of IE. Be certain the patient understands the importance of prophylactic antibiotic therapy before certain invasive procedures. Refer the patient with a history of IVDA for drug rehabilitation.

AMBULATORY AND HOME CARE. A patient with IE has many problems that require nursing management (see eNursing Care Plan 37-1 on the website for this chapter). IE generally requires treatment with antibiotics for 4 to 6 weeks. After initial treatment in the hospital, the patient may continue treatment at home if hemodynamically stable and adherent. Assess the home setting for adequate support. Patients who receive outpatient IV antibiotics require vigilant home nursing care.

Assessment findings are often nonspecific (see Table 37-3) but can help with the treatment plan. Fever, chronic or intermittent, is a common early sign. Instruct the patient or caregiver about the importance of monitoring body temperature. Persistent temperature elevations may mean that the drug therapy is ineffective. Patients with IE are at risk for life-threatening complications, such as stroke, pulmonary edema, and HF. Teach patients and caregivers to recognize signs and symptoms of these complications (e.g., change in mental status, dyspnea, chest pain, unexplained weight gain).

The patient with IE needs adequate periods of physical and emotional rest. Bed rest may be necessary when the patient has fever or complications (e.g., heart damage). Otherwise the patient may ambulate and perform moderate activity. To prevent problems related to reduced mobility, tell the patient to wear elastic compression stockings, perform ROM exercises, and deep breathe and cough every 2 hours.

The patient may experience anxiety and fear associated with the illness. You must recognize this and implement strategies to help the patient cope with the illness.

Monitor laboratory data to determine the effectiveness of the antibiotic therapy. Ongoing monitoring of the patient's blood cultures is necessary to ensure destruction of the infecting organism. Assess IV lines for patency and signs of complications (e.g., phlebitis). Administer antibiotics as scheduled, and monitor the patient for any adverse drug reactions.

Management also focuses on teaching the patient and caregiver the nature of the disease and on reducing the risk of reinfection. Explain to the patient the relationship of follow-up care, good nutrition, and early treatment of common infections (e.g., colds) to maintain health. Instruct the patient about symptoms that may indicate recurrent infection (e.g., fever, fatigue, chills). Tell the patient to notify the health care provider if any of these symptoms occur. Finally, inform the patient about the importance of prophylactic antibiotic therapy before certain invasive procedures (see Table 37-2).

EVALUATION

The expected outcomes are that the patient with IE will

- Maintain adequate tissue and organ perfusion
- Maintain normal body temperature
- Report an increase in physical and emotional comfort

Additional information on expected outcomes for the patient with IE are presented in eNursing Care Plan 37-1 on the website for this chapter.

ACUTE PERICARDITIS

Pericarditis is a condition caused by inflammation of the pericardial sac (the pericardium).The pericardium is composed of the inner serous membrane (visceral pericardium) and the outer fibrous (parietal) layer (see Fig. 37-1). The pericardial space is the cavity between these two layers. Normally it contains 10 to 15 mL of serous fluid. The pericardium serves an anchoring function, provides lubrication to decrease friction during systolic and diastolic heart movements, and assists in preventing excessive dilation of the heart during diastole. It may be congenitally absent or surgically removed.

TABLE 37-4 COMMON CAUSES OF PERICARDITIS

Infectious
- Viral: Coxsackie A and B virus, echovirus, adenovirus, mumps, hepatitis, Epstein-Barr, varicella zoster, human immunodeficiency virus
- Bacterial: Pneumococci, staphylococci, streptococci, *Neisseria gonorrhoeae, Legionella pneumophila, Mycobacterium tuberculosis,* septicemia from gram-negative organisms
- Fungal: *Histoplasma, Candida* species
- Others: Toxoplasmosis, Lyme disease

Noninfectious
- Uremia
- Acute myocardial infarction
- Neoplasms: Lung cancer, breast cancer, leukemia, Hodgkin's lymphoma, non-Hodgkin's lymphoma
- Trauma: Thoracic surgery, pacemaker insertion, cardiac diagnostic procedures
- Radiation
- Dissecting aortic aneurysm
- Myxedema

Hypersensitive or Autoimmune
- Dressler syndrome
- Postpericardiotomy syndrome
- Rheumatic fever
- Drug reactions (e.g., procainamide [Pronestyl], hydralazine [Apresoline])
- Rheumatologic diseases: Rheumatoid arthritis, systemic lupus erythematosus, systemic sclerosis (scleroderma), ankylosing spondylitis

Etiology and Pathophysiology

Common causes of acute pericarditis are listed in Table 37-4. Most often the cause of acute pericarditis is *idiopathic* (unknown), with a variety of suspected viral causes. The coxsackie B virus is the most commonly identified virus.[8]

Pericarditis in the patient with an MI may be described as two distinct syndromes. The first is *acute pericarditis,* which may occur within the initial 48 to 72 hours after an MI. The second is *Dressler syndrome* (late pericarditis), which appears 4 to 6 weeks after an MI (see Chapter 34). An inflammatory response is the characteristic pathologic finding in acute pericarditis. There is an influx of neutrophils, increased pericardial vascularity, and eventually fibrin deposition on the epicardium (Fig. 37-4).

Clinical Manifestations

In acute pericarditis, clinical manifestations include progressive, frequently severe, sharp chest pain. The pain is generally worse with deep inspiration and when lying supine. It is relieved by sitting up and leaning forward. The pain may radiate to the neck, arms, or left shoulder, making it difficult to differentiate from angina. One distinction is that the pain from pericarditis can be referred to the trapezius muscle (shoulder, upper back), since the phrenic nerve innervates this region. The dyspnea that accompanies acute pericarditis is related to the patient's need to breathe in rapid, shallow breaths to avoid chest pain and may be aggravated by fever and anxiety.

The hallmark finding in acute pericarditis is the *pericardial friction rub.* The rub is a scratching, grating, high-pitched sound believed to result from friction between the roughened pericardial and epicardial surfaces. It is best heard with the stethoscope placed at the lower left sternal border of the chest with the patient leaning forward. Since it is difficult to distinguish a pericardial friction rub from a pleural friction rub, ask the patient to hold his or her breath. If you still hear the rub, then it is cardiac. It may require frequent attempts to identify because pericardial friction rubs are often intermittent and short lived.

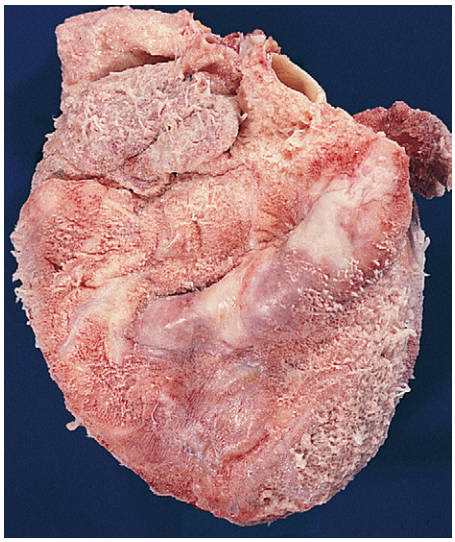

FIG. 37-4 Acute pericarditis. Note shaggy coat of fibers covering surface of heart.

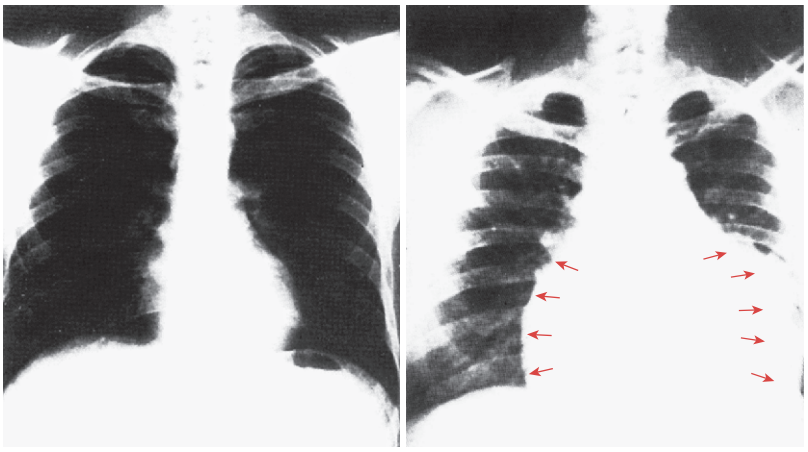
Complications



Two major complications that may result from acute pericarditis are pericardial effusion and cardiac tamponade. *Pericardial effusion* is a build-up of fluid in the pericardium. It can occur rapidly (e.g., chest trauma) or slowly (e.g., tuberculosis pericarditis). Large effusions may compress nearby structures. Pulmonary tissue compression can cause cough, dyspnea, and tachypnea. Phrenic nerve compression can induce hiccups, and compression of the laryngeal nerve may result in hoarseness. Heart sounds are generally distant and muffled, although blood pressure (BP) usually is maintained.

Cardiac tamponade develops as the pericardial effusion increases in volume. This results in compression of the heart. The speed of fluid accumulation affects the severity of clinical manifestations. Cardiac tamponade can occur acutely (e.g., rupture of heart, trauma) or subacutely (e.g., secondary to renal failure, malignancy).

The patient with cardiac tamponade may report chest pain and is often confused, anxious, and restless. As the compression of the heart increases, there is decreased cardiac output (CO), muffled heart sounds, and narrowed pulse pressure. The patient develops tachypnea and tachycardia. Neck veins usually are markedly distended because of increased jugular venous pressure, and pulsus paradoxus is present. *Pulsus paradoxus* is a decrease in systolic BP during inspiration that is exaggerated in cardiac tamponade. (See Table 37-5 for the measurement technique.) In a patient with a slow onset of a cardiac tamponade, dyspnea may be the only clinical manifestation.

Diagnostic Studies

The ECG is useful in the diagnosis of acute pericarditis, with changes noted in approximately 90% of the cases. The most

A B

FIG. 37-5 **A,** X-ray of a normal chest. **B,** Pericardial effusion is present, and the cardiac silhouette is enlarged with a globular shape *(arrows)*.

TABLE 37-5 MEASUREMENT OF PULSUS PARADOXUS

1. Position the patient in a semirecumbent position.
2. Instruct patient to breathe normally.*
2. Using a manually operated blood pressure (BP) cuff, determine systolic BP.
3. Inflate BP cuff at least 20 mm Hg above systolic BP.
4. Deflate cuff slowly until you hear the first Korotkoff sound during expiration, and note the pressure.
5. Continue to slowly deflate cuff until you hear sounds throughout the respiratory cycle (inspiration and expiration), and note the pressure.
6. Determine the difference between the measurements taken in steps 4 and 5. This will equal the amount of paradox:

Sounds heard on expiration at	110 mm Hg
Sounds heard throughout cycle at	– 82 mm Hg
Amount of paradox	28 mm Hg

The difference is normally <10 mm Hg. If the difference is >10 mm Hg, cardiac tamponade may be present.

*Ask the patient to breathe slowly and deeply to reveal this finding when pulsus paradoxus is not severe.

sensitive ECG changes include diffuse (widespread) ST segment elevations. This reflects the abnormal repolarization that develops secondary to the pericardial inflammation. You need to differentiate these changes from the ST changes seen with MI. (See Chapter 36 for more information on ECG monitoring.)

Echocardiographic findings are most useful in determining the presence of a pericardial effusion or cardiac tamponade. Methods such as Doppler imaging and color M-mode assess diastolic function and diagnose constrictive pericarditis (discussed later in the chapter). Computed tomography (CT) and magnetic resonance imaging (MRI) provide for visualization of the pericardium and pericardial space. Chest x-ray findings are generally normal, but cardiomegaly may be seen in a patient who has a large pericardial effusion (Fig. 37-5).

Common laboratory findings include leukocytosis and elevation of CRP and ESR. Troponin levels may be elevated in patients with ST segment elevation and acute pericarditis, which could indicate concurrent myocardial damage. The fluid obtained during pericardiocentesis or the tissue from a pericardial biopsy may be studied to determine the cause of the pericarditis.

TABLE 37-6 COLLABORATIVE CARE

Acute Pericarditis

Diagnostic	Collaborative Therapy
• History and physical examination: pericardial friction rub, pulsus paradoxus • Laboratory: CRP, ESR, white blood cell count • Electrocardiogram • Chest x-ray • Echocardiogram • Computed tomography • Magnetic resonance imaging • Pericardiocentesis, pericardial window • Pericardial biopsy	• Treatment of underlying disease • Bed rest • Nonsteroidal antiinflammatory drugs • Corticosteroids • Pericardiocentesis (for tamponade) • Pericardial window (for tamponade or ongoing pericardial effusion)

CRP, C-reactive protein; *ESR,* erythrocyte sedimentation rate.

Collaborative Care

Management of acute pericarditis is aimed at identifying and treating the underlying problem and symptoms (Table 37-6). Antibiotics treat bacterial pericarditis, and nonsteroidal antiinflammatory drugs (NSAIDs) (e.g., salicylates [aspirin], ibuprofen) control the pain and inflammation. Corticosteroids are generally reserved for patients with pericarditis secondary to systemic lupus erythematosus, patients already taking corticosteroids for rheumatologic or other autoimmune conditions, or patients who do not respond to NSAIDs. They are used cautiously because of their numerous side effects (see Chapter 50). Colchicine (Colsalide), an antiinflammatory drug used for gout, can be used for patients who have recurrent pericarditis.[9]

Pericardiocentesis is usually performed for pericardial effusion with acute cardiac tamponade, purulent pericarditis, and suspected neoplasm. Hemodynamic support for the patient being prepared for the pericardiocentesis may include administration of volume expanders and inotropic agents (e.g., dopamine [Intropin]) and the discontinuation of any anticoagulants. The procedure is performed rapidly and safely using a percutaneous approach that is guided by echocardiography (Fig. 37-6). A needle is inserted into the pericardial space to remove fluid for analysis and to relieve cardiac pressure. Complications from pericardiocentesis include dysrhythmias, further cardiac tam-

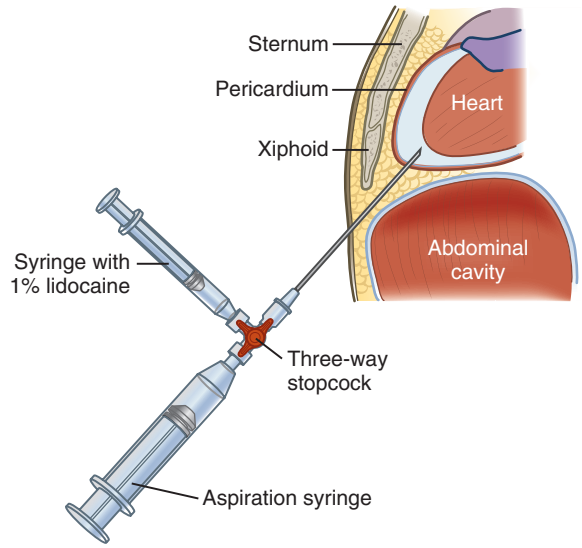


FIG. 37-6 Pericardiocentesis performed under sterile conditions in conjunction with electrocardiogram (ECG) and hemodynamic measurements.

ponade, pneumomediastinum, pneumothorax, myocardial laceration, and coronary artery laceration.

A *pericardial window* can be used for diagnosis or for drainage of excess fluid. It involves cutting a "window" or portion of the pericardium. This allows the fluid to drain continuously into the peritoneum or chest.

NURSING MANAGEMENT ACUTE PERICARDITIS

The management of the patient's pain and anxiety during acute pericarditis is your primary nursing consideration. Assess the pain to distinguish the pain of myocardial ischemia (angina) from the pain of pericarditis (see Table 34-7). Pericarditic pain is usually located in the precordium or left trapezius region and has a sharp, pleuritic quality that increases with inspiration. Pain is often relieved when the patient sits up or leans forward, and is worse when lying supine. The ECG can aid in distinguishing these types of pain. In acute pericarditis there are diffuse ST segment elevations. In myocardial ischemia there are usually localized ST segment changes. In addition, in acute pericarditis serial ECGs do not show evolving changes like those with MI.

Pain relief measures include keeping the patient on bed rest with the head of the bed elevated to 45 degrees and providing an overbed table for support. Antiinflammatory medications can help control the pain. However, because of the risk of gastrointestinal (GI) bleeding, administer these drugs with food or milk and instruct the patient to avoid alcohol. Other medications, such as a proton pump inhibitor (e.g., pantoprazole [Protonix]), may be ordered to decrease stomach acid.

Anxiety-reducing measures for the patient with acute pericarditis include providing simple, complete explanations of all procedures and possible causes of the pain. These explanations are particularly important for the patient whose diagnosis of acute pericarditis is being established and for the patient who has previously experienced angina or an acute MI.

The patient with acute pericarditis is at risk for cardiac tamponade and decreased CO. Monitor for the signs and symptoms of tamponade and prepare for possible pericardiocentesis.

CHRONIC CONSTRICTIVE PERICARDITIS

Etiology and Pathophysiology

Chronic constrictive pericarditis results from scarring with consequent loss of elasticity of the pericardial sac. It usually begins with an initial episode of acute pericarditis and is characterized by fibrin deposition with a clinically undetected pericardial effusion. Reabsorption of the effusion slowly follows, with progression toward the chronic stage. This involves fibrous scarring, thickening of the pericardium from calcium deposition, and eventual destruction of the pericardial space. The fibrotic, thickened, and adherent pericardium encases the heart, thereby impairing the ability of the atria and ventricles to stretch adequately.

Clinical Manifestations and Diagnostic Studies

Manifestations of chronic constrictive pericarditis occur over time and mimic those of HF and cor pulmonale. Decreased CO accounts for many of the clinical manifestations, including dyspnea on exertion, peripheral edema, ascites, fatigue, anorexia, and weight loss. The most prominent finding on physical examination is jugular venous distention (JVD). Unlike with cardiac tamponade, the presence of pulsus paradoxus (greater than 10 mm Hg) is not common.

ECG changes are often nonspecific in chronic constrictive pericarditis. The heart on the chest x-ray may be normal or enlarged depending on the degree of pericardial thickening and the presence of a pericardial effusion. 2-D echocardiography findings may reveal a thickened pericardium, but without a large pericardial effusion. CT and MRI provide measurement of pericardial thickness and assessment of diastolic filling patterns.

NURSING AND COLLABORATIVE MANAGEMENT CHRONIC CONSTRICTIVE PERICARDITIS

Unless the patient is free of symptoms or the condition is inoperable, the treatment of choice for chronic constrictive pericarditis is a *pericardiectomy.* This involves complete resection of the pericardium through a median sternotomy with the use of cardiopulmonary bypass (see Chapter 34). Some patients show immediate improvement after surgery, but others may take weeks. The prognosis improves when surgery is performed before the patient becomes clinically unstable.

MYOCARDITIS

Etiology and Pathophysiology

Myocarditis is a focal or diffuse inflammation of the myocardium. Possible causes include viruses, bacteria, fungi, radiation therapy, and pharmacologic and chemical factors. Coxsackie A and B viruses are the most common etiologic agents. Autoimmune disorders (e.g., polymyositis) also have been associated with the development of myocarditis. It may also be idiopathic. Myocarditis is frequently associated with acute pericarditis, particularly when it is caused by coxsackie B virus.[10]

When the myocardium becomes infected, the causative agent invades the myocytes and causes cellular damage and necrosis. The immune response is activated, and cytokines and oxygen free radicals are released. As the infection progresses, an autoimmune response is activated. This causes further destruction of myocytes. Myocarditis results in cardiac dysfunc-

tion and has been linked to the development of dilated cardiomyopathy (discussed later in this chapter).

Clinical Manifestations

The clinical features of myocarditis are variable, ranging from a benign course without any overt manifestations to severe heart involvement or sudden cardiac death (SCD). Fever, fatigue, malaise, myalgias, pharyngitis, dyspnea, lymphadenopathy, and nausea and vomiting are early systemic manifestations of the viral illness.

Early cardiac signs appear 7 to 10 days after viral infection. These include pleuritic chest pain with a pericardial friction rub and effusion because pericarditis often accompanies myocarditis. Late cardiac signs relate to the development of HF and may include an S_3 heart sound, crackles, JVD, syncope, peripheral edema, and angina.

Diagnostic Studies and Collaborative Care

The ECG changes for a patient with myocarditis are often nonspecific but may reflect associated pericardial involvement (e.g., diffuse ST segment changes). Dysrhythmias and conduction disturbances may be present. Laboratory findings are often inconclusive. They may include mild to moderate leukocytosis and atypical lymphocytes, increased ESR and CRP levels, elevated levels of myocardial markers such as troponin, and elevated viral titers. The virus is generally present in tissue and pericardial fluid samples only during the initial 8 to 10 days of illness.

Histologic confirmation of myocarditis is through an *endomyocardial biopsy.* A biopsy done during the first 6 weeks of acute illness is most diagnostic. This is the period in which lymphocytic infiltration and myocyte damage are present. Nuclear scans, echocardiography, and MRI are used to assess cardiac function.

The treatment for myocarditis consists of managing associated heart symptoms. Angiotensin-converting enzyme (ACE) inhibitors and β-adrenergic blockers are used if the heart is enlarged or to treat HF (see Chapter 35). Diuretics reduce fluid volume and decrease preload. If hypotension is not present, IV medications such as nitroprusside (Nitropress) and milrinone (Primacor) reduce afterload and improve CO by decreasing systemic vascular resistance. Digoxin (Lanoxin) improves myocardial contractility and reduces the heart rate. However, it is used cautiously in patients with myocarditis because of the heart's increased sensitivity to the adverse effects of this drug (e.g., dysrhythmias) and the potential toxicity. Anticoagulation therapy reduces the risk of thrombus formation from blood stasis in patients with a low ejection fraction (EF).

DRUG ALERT: Digoxin (Lanoxin)

- Use cautiously in patients with myocarditis, since the condition predisposes patients to drug-related dysrhythmias and toxicity.

Because myocarditis may have an autoimmune basis, immunosuppressive agents have been used to reduce myocardial inflammation and prevent irreversible myocardial damage. However, the use of these agents for the treatment of myocarditis remains controversial.[11]

General supportive measures for management of myocarditis include oxygen therapy, bed rest, and restricted activity. In cases of severe HF, intraaortic balloon pump therapy and ventricular assist devices may be required (see Chapters 35 and 66).

NURSING MANAGEMENT MYOCARDITIS

Decreased CO is an ongoing nursing diagnosis in the care of the patient with myocarditis. Focus your interventions on managing the signs and symptoms of HF. Select nursing measures to decrease cardiac workload. These include placing the patient in a semi-Fowler's position, spacing activity and rest periods, and providing a quiet environment. Carefully monitor medications that increase the heart's contractility and decrease preload, afterload, or both. Evaluate the effectiveness of your interventions on an ongoing basis.

The patient may be anxious about the diagnosis of myocarditis and recovery. Assess the level of anxiety, take measures to decrease anxiety, and keep the patient and caregiver informed about the therapeutic plan.

The patient who receives immunosuppressive therapy is at increased risk for infection. Monitor for complications and provide the patient with proper infection control procedures.

Most patients with myocarditis recover spontaneously, although some may develop dilated cardiomyopathy (discussed later in this chapter). If severe HF occurs, the patient may require heart transplantation.

RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

Rheumatic fever (RF) is an acute inflammatory disease of the heart potentially involving all layers (endocardium, myocardium, and pericardium). **Rheumatic heart disease** is a chronic condition resulting from RF that is characterized by scarring and deformity of the heart valves.

Etiology and Pathophysiology

RF is a complication that occurs as a delayed result (usually after 2 to 3 weeks) of a group A streptococcal pharyngitis. Symptoms of RF appear to be related to an abnormal immunologic response to group A streptococcal cell membrane antigens.[12] RF affects the heart, skin, joints, and central nervous system (CNS).

RF has declined in developed countries because of the effective use of antibiotics to treat streptococcal infections. However, it remains an important public health problem in developing countries.[12] Rheumatic heart disease, caused by RF, primarily affects young adults.

Cardiac Lesions and Valve Deformities. About 40% of RF episodes are marked by carditis, meaning that all layers of the heart (endocardium, myocardium, and pericardium) are involved (see Fig. 37-1). This gives rise to the term *rheumatic pancarditis.*

Rheumatic endocarditis is found mainly in the valves, with swelling and erosion of the valve leaflets. Vegetation forms from deposits of fibrin and blood cells in areas of erosion (see eFig. 37-1 on the website for this chapter). The lesions initially create thickening of the valve leaflets, fusion of commissures and chordae tendineae, and fibrosis of the papillary muscle. Valve leaflets may become calcified, resulting in stenosis. The less mobile valve leaflets may not close properly, resulting in regurgitation. The mitral and aortic valves are most commonly affected.

Nodules, called *Aschoff's bodies,* are formed by a reaction to inflammation with swelling and destruction of collagen fibers. As the Aschoff's bodies age, they become more fibrous, and scar

TABLE 37-7 MODIFIED JONES CRITERIA FOR DIAGNOSING RHEUMATIC FEVER

Major Criteria
- Carditis
- Monoarthritis or polyarthritis
- Sydenham's chorea
- Erythema marginatum
- Subcutaneous nodules

Minor Criteria
- Clinical findings: Fever, polyarthralgia
- Laboratory findings: ↑ ESR, ↑ WBC count, ↑ CRP
- ECG findings: Prolonged PR interval

Evidence of Group A Streptococcal Infection
- Laboratory findings: ↑ Antistreptolysin-O titer, positive throat culture, positive rapid antigen test for group A streptococci

Source: American Heart Association: Scientific statement: proceedings of the Jones criteria workshop, *Circulation* 106:2521, 2002.
CRP, C-reactive protein; *ESR,* erythrocyte sedimentation rate.

tissue forms in the myocardium. Rheumatic pericarditis develops and affects both layers of the pericardium. The layers become thickened and covered with a fibrinous exudate. A serosanguineous pericardial effusion may develop. When healing occurs, fibrosis and adhesions develop that partially or completely destroy the pericardial sac. These pathophysiologic changes in the heart can begin during an initial attack of RF. Recurrent infections cause further structural damage.

Extracardiac Lesions. The lesions of RF are systemic and involve the skin, joints, and CNS. Painless subcutaneous nodules, arthralgias or arthritis, and chorea may develop.

Clinical Manifestations

A cluster of signs and symptoms, including laboratory findings, leads to the diagnosis of RF. Established criteria provide a basis for diagnosis.[13] The presence of two major criteria or one major and two minor criteria plus evidence of a preceding group A streptococcal infection indicate a high probability of RF (Table 37-7).

Major Criteria. *Carditis* is the most important manifestation of RF and results in three signs: (1) a heart murmur or murmurs of mitral or aortic regurgitation, or mitral stenosis; (2) cardiac enlargement and HF secondary to myocarditis; and (3) pericarditis resulting in muffled heart sounds, chest pain, pericardial friction rub, or signs of effusion.

Monoarthritis or *polyarthritis* is the most common finding in RF. The inflammatory process affects the synovial membranes of the joints, causing swelling, heat, redness, tenderness, and limitation of motion. The larger joints, particularly the knees, ankles, elbows, and wrists, are most frequently affected.

Sydenham's chorea is the major CNS manifestation of RF. It is often a delayed sign occurring several months after the initial infection. It is characterized by involuntary movements, especially of the face and limbs; muscle weakness; and disturbances of speech and gait.

Erythema marginatum lesions are a less common feature of RF. The bright pink, nonpruritic, maplike macular lesions occur mainly on the trunk and proximal extremities, and may be exacerbated by heat (e.g., warm bath).

Subcutaneous nodules, usually associated with severe carditis, are firm, small, hard, painless swellings located over extensor surfaces of joints, particularly the knees, wrists, and elbows.

TABLE 37-8 COLLABORATIVE CARE

Rheumatic Fever

Diagnostic
- History and physical examination
- Laboratory findings (see Table 37-7)
- Chest x-ray
- Echocardiogram
- Electrocardiogram

Collaborative Therapy
- Bed rest
- Antibiotics
- Nonsteroidal antiinflammatory drugs
- Salicylates
- Corticosteroids

Minor Criteria. Minor clinical manifestations (see Table 37-7) are frequently present and are helpful in diagnosing the disease. The minor criteria are used as supplemental data to confirm the presence of RF when only one major criterion is present.

Evidence of Infection. In addition to the major and minor criteria, there must also be evidence of a preceding group A streptococcal infection. Table 37-7 lists the various laboratory tests used to confirm evidence of infection.

Complications

A complication that can result from RF is *chronic rheumatic carditis.* It results from changes in valvular structure that may occur months to years after an episode of RF. Rheumatic endocarditis can result in fibrous tissue growth in valve leaflets and chordae tendineae with scarring and contractures. The mitral valve is most frequently involved. The aortic and tricuspid valves may also be affected.

Diagnostic Studies and Collaborative Care

No single diagnostic test exists for RF. An echocardiogram may show valvular insufficiency and pericardial fluid or thickening.[14] A chest x-ray may show an enlarged heart if HF is present. The most consistent ECG change is delayed AV conduction as evidenced by a prolonged PR interval.

Treatment consists of drug therapy and supportive measures (Table 37-8). Antibiotic therapy does not change the course of the acute disease or the development of carditis. It does eliminate residual group A streptococci remaining in the tonsils and pharynx and prevents the spread of organisms to close contacts. Salicylates, NSAIDs, and corticosteroids are the antiinflammatory agents most widely used in the management of RF. All are effective in controlling the fever and joint manifestations. Salicylates or NSAIDs are used when arthritis is the main manifestation, and corticosteroids are used if severe carditis is present.

NURSING MANAGEMENT RHEUMATIC FEVER AND RHEUMATIC HEART DISEASE

NURSING ASSESSMENT

Table 37-9 presents the subjective and objective data that you should obtain from a patient with RF and rheumatic heart disease.

Inspect the patient's skin for subcutaneous nodules and erythema marginatum. This involves palpating for subcutaneous nodules over all bony surfaces and along extensor tendons of

TABLE 37-9 NURSING ASSESSMENT

Rheumatic Fever and Rheumatic Heart Disease

Subjective Data

Important Health Information

Past health history: Recent streptococcal infection, previous history of rheumatic fever or rheumatic heart disease

Functional Health Patterns

Health perception–health management: Family history of rheumatic fever; malaise

Nutritional-metabolic: Anorexia, weight loss

Activity-exercise: Palpitations; generalized weakness, fatigue; ataxia

Cognitive-perceptual: Chest pain; widespread joint pain and tenderness (especially large joints)

Objective Data

General

Fever

Integumentary

Subcutaneous nodules and erythema marginatum

Cardiovascular

Tachycardia, pericardial friction rub, muffled heart sounds; murmurs; peripheral edema

Neurologic

Chorea (involuntary, purposeless, rapid motions; facial grimaces)

Musculoskeletal

Signs of monoarthritis or polyarthritis, including swelling, heat, redness, limitation of motion (especially of knees, ankles, elbows, shoulders, wrists)

Possible Diagnostic Findings

Cardiomegaly on chest x-ray; prolonged PR interval on ECG; valve abnormalities, chamber dilation, and pericardial effusion on echocardiogram; ↑ antistreptolysin-O titer, positive throat culture, positive rapid antigen test for group A streptococci; ↑ ESR, ↑ CRP, leukocytosis

CRP, C-reactive protein; *ESR*, erythrocyte sedimentation rate.

the hands and feet. The nodules range in size from 1 to 4 cm and are hard, painless, and freely movable. Erythema marginatum can occur on the trunk and inner aspects of the upper arm and thigh. The erythematous maculae do not itch and are flat. Assess for these bright pink maculae in good light because the rash is difficult to observe, especially in dark-skinned patients.

NURSING DIAGNOSES

Nursing diagnoses for the patient with RF and rheumatic heart disease may include, but are not limited to, the following:

- Decreased CO *related to* valve dysfunction or HF
- Activity intolerance *related to* arthralgia or arthritis secondary to joint pain, pain from pericarditis, and HF
- Ineffective self–health management *related to* lack of knowledge concerning possible disease sequelae and the need for long-term prophylactic antibiotic therapy

PLANNING

The goals for a patient with RF and rheumatic heart disease include (1) normal or baseline heart function, (2) resumption of daily activities without joint pain, and (3) verbalization of the ability to manage the disease sequelae.

NURSING IMPLEMENTATION

HEALTH PROMOTION. RF is a preventable cardiovascular disease. It involves early detection and immediate treatment of group A streptococcal pharyngitis. Adequate treatment of streptococcal pharyngitis prevents initial attacks of RF. Treatment with oral penicillin V (Penicillin VK) or amoxicillin (Moxatag) for 10 days is recommended. If the patient is allergic to penicillin, a narrow-spectrum cephalosporin (e.g., cephalexin [Keflex]), clindamycin (Cleocin), or azithromycin (Zithromax) is used.[15] Therapy requires strict adherence to the full course of treatment. Your role is to teach the community to seek medical attention for symptoms of streptococcal pharyngitis and to emphasize the need for prompt and adequate treatment.

ACUTE INTERVENTION. The primary goals of managing a patient with RF are to (1) control and remove the infecting organism; (2) prevent cardiac complications; and (3) relieve joint pain, fever, and other symptoms. Administer antibiotics as ordered to treat the streptococcal infection. Teach the patient that completing the full course of antibiotics is vital to successful treatment. Administer salicylates, NSAIDs, and corticosteroids as prescribed, and monitor fluid intake as appropriate.

Promoting optimal rest is essential to reduce cardiac workload and the body's metabolic needs. A priority nursing goal is relief of joint pain. Position painful joints for comfort and in proper alignment. Heat may be applied and salicylates or NSAIDs administered for joint pain.

After the acute symptoms have subsided, the patient without carditis can ambulate. If the patient has carditis with HF, strict bed rest restrictions apply (see Chapter 35 for care of a patient with HF). Encourage nonstrenuous activities once recovery has begun.

AMBULATORY AND HOME CARE. Secondary prevention aims at stopping the recurrence of RF. Teach the patient with a history of RF about the disease process, possible sequelae, and the need for continuous antibiotic prophylaxis.

Prior history of RF makes the patient more susceptible to a second attack after a streptococcal infection. The best prevention is treatment with prophylactic antibiotics. Patients with RF without carditis require prophylaxis until age 20 and for a minimum of 5 years. Patients with rheumatic carditis and residual heart disease (e.g., persistent valve disease) need longer-term and even life-long prophylaxis.[13]

Teach the patient about good nutrition, hygienic practices, and adequate rest. Caution the patient about the possible development of heart valve disease. Teach the patient to seek medical attention if symptoms such as excessive fatigue, dizziness, palpitations, unexplained weight gain, or exertional dyspnea develop.[16]

EVALUATION

The expected outcomes for the patient with RF and rheumatic heart disease include

- Ability to perform ADLs with minimal fatigue and pain
- Adherence to treatment regimen
- Expression of confidence in managing disease
- Prevention of complications

VALVULAR HEART DISEASE

The heart contains two AV valves (mitral and tricuspid) and two semilunar valves (aortic and pulmonic), which control unidirectional blood flow (see Fig. 32-1). Valvular heart disease is

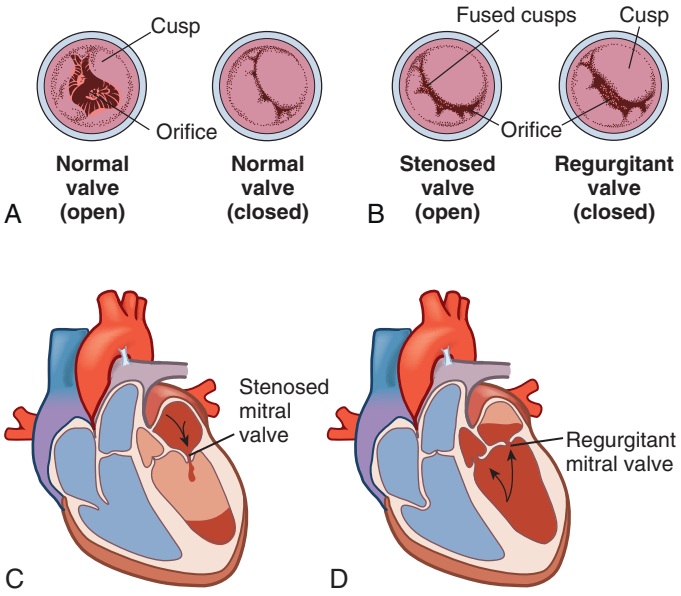

FIG. 37-7 Valvular stenosis and regurgitation. **A,** Normal position of the valve leaflets, or cusps, when the valve is open and closed. **B,** Open position of a stenosed valve *(left)* and closed position of regurgitant valve *(right)*. **C,** Hemodynamic effect of mitral stenosis. The stenosed valve is unable to open sufficiently during left atrial systole, inhibiting left ventricular filling. **D,** Hemodynamic effect of mitral regurgitation. The mitral valve does not close completely during left ventricular systole, permitting blood to reenter the left atrium. At the same time, blood is moving forward through the aortic valve.

defined according to the valve or valves affected and the type of functional alteration: stenosis or regurgitation (Fig. 37-7).

The pressure on either side of an open valve is normally equal. However, in a stenotic valve, the valve opening is smaller. The forward flow of blood is impaired. This creates a difference in pressure on the two sides of the open valve. The amount of **stenosis** (constriction or narrowing) is seen in the pressure differences (i.e., the higher the difference, the greater the stenosis). In **regurgitation** (also called *incompetence* or *insufficiency*), incomplete closure of the valve results in the backward flow of blood.

Valve disorders occur in children and adolescents mainly from congenital conditions. Valvular heart disease remains prevalent because of an increased number of older adults who have some form of cardiovascular disease. AS and mitral regurgitation (MR) are common valve disorders in older adults. Other causes of valve disease in adults include disorders related to acquired immunodeficiency syndrome and the use of some antiparkinsonian drugs.[17]

MITRAL VALVE STENOSIS

Etiology and Pathophysiology

Most cases of adult mitral valve stenosis result from rheumatic heart disease. Rheumatic mitral stenosis is widespread in developing countries. Less common causes are congenital mitral stenosis, rheumatoid arthritis, and systemic lupus erythematosus. Rheumatic endocarditis causes scarring of the valve leaflets and the chordae tendineae. Contractures and adhesions develop between the commissures (the junctional areas). The stenotic mitral valve takes on a "fish mouth" shape because of the thickening and shortening of the mitral valve structures (see eFig. 37-2 on the website for this chapter). These deformities block the blood flow and create a pressure difference between the left atrium and the left ventricle during diastole. Left atrial pressure and volume increase. This causes higher pulmonary vasculature pressure. The overloaded left atrium places the patient at risk for atrial fibrillation. In chronic mitral stenosis, pressure overload occurs in the left atrium, the pulmonary bed, and the right ventricle.

TABLE 37-10 MANIFESTATIONS OF VALVULAR HEART DISEASE

Type	Manifestations
Mitral valve stenosis	Dyspnea on exertion, hemoptysis; fatigue; atrial fibrillation on ECG, palpitations, stroke; loud, accentuated S_1; low-pitched, diastolic murmur
Mitral valve regurgitation	*Acute:* Generally poorly tolerated; new systolic murmur with pulmonary edema and cardiogenic shock developing rapidly *Chronic:* Weakness, fatigue, exertional dyspnea, palpitations; an S_3 gallop, holosystolic murmur
Mitral valve prolapse	Palpitations, dyspnea, chest pain, activity intolerance, syncope; or holosystolic murmur
Aortic valve stenosis	Angina, syncope, dyspnea on exertion, heart failure; normal or soft S_1, diminished or absent S_2, systolic murmur, prominent S_4
Aortic valve regurgitation	*Acute:* Abrupt onset of profound dyspnea, chest pain, left ventricular failure and cardiogenic shock *Chronic:* Fatigue, exertional dyspnea, orthopnea, PND; water-hammer pulse; heaving precordial impulse; diminished or absent S_1, S_3, or S_4; soft high-pitched diastolic murmur, Austin Flint murmur
Tricuspid and pulmonic stenosis	*Tricuspid:* Peripheral edema, ascites, hepatomegaly; diastolic low-pitched murmur with increased intensity during inspiration *Pulmonic:* Fatigue, loud midsystolic murmur

PND, Paroxysmal nocturnal dyspnea.

Clinical Manifestations

The primary symptom of mitral stenosis is exertional dyspnea caused by reduced lung compliance (Table 37-10). Heart sounds include a loud first heart sound and a low-pitched, diastolic murmur (best heard at the apex with the stethoscope). Less frequently, patients may have hoarseness (from atrial enlargement pressing on the laryngeal nerve), hemoptysis (from pulmonary hypertension), chest pain (from decreased CO and coronary perfusion), and seizures or a stroke (from emboli). Fatigue and palpitations from atrial fibrillation may also occur. Emboli can arise from blood stasis in the left atrium secondary to atrial fibrillation.[18]

MITRAL VALVE REGURGITATION

Etiology and Pathophysiology

Mitral valve function depends on intact mitral leaflets, mitral annulus, chordae tendineae, papillary muscles, left atrium, and left ventricle. A defect in any of these structures can result in regurgitation. Most cases of mitral regurgitation (MR) are caused by MI, chronic rheumatic heart disease, mitral valve prolapse, ischemic papillary muscle dysfunction, and IE. MI with left ventricular failure increases the risk for rupture of the chordae tendineae and acute MR.

MR allows blood to flow backward from the left ventricle to the left atrium because of incomplete valve closure during

systole. Both the left ventricle and left atrium must work harder to preserve an adequate CO. In acute MR the sudden increase in pressure and volume transmits to the pulmonary bed. This results in pulmonary edema and, if untreated, cardiogenic shock. In chronic MR the additional volume results in left atrial enlargement, left ventricular dilation and hypertrophy, and, finally, a decrease in CO.

Clinical Manifestations

The clinical course of MR is determined by the nature of its onset (see Table 37-10). Patients with acute MR have thready, peripheral pulses and cool, clammy extremities. A low CO may mask a new systolic murmur. Rapid assessment (e.g., cardiac catheterization) and intervention (e.g., valve repair or replacement) are critical.

Patients with chronic MR may remain asymptomatic for many years. Initial symptoms of left ventricular failure may include weakness, fatigue, palpitations, and dyspnea that gradually progress to orthopnea, paroxysmal nocturnal dyspnea, and peripheral edema. Increased left ventricular volume leads to an audible third heart sound (S_3), even with normal left ventricular function. The murmur is a loud holosystolic murmur at the apex radiating to the left axilla. Patients with asymptomatic MR must be monitored carefully. Surgery (valve repair or replacement) should be considered before significant left ventricular failure or pulmonary hypertension develops.[19]

MITRAL VALVE PROLAPSE

Etiology and Pathophysiology

Mitral valve prolapse (MVP) is an abnormality of the mitral valve leaflets and the papillary muscles or chordae that allows the leaflets to prolapse, or buckle, back into the left atrium during systole (Fig. 37-8). It is the most common form of valvular heart disease in the United States. It affects both genders equally.[20]

The use of the term *prolapse* can be misleading because it is used even when the valve is working normally. MVP is usually benign, but serious complications can occur, including MR, IE, SCD, HF, and cerebral ischemia.

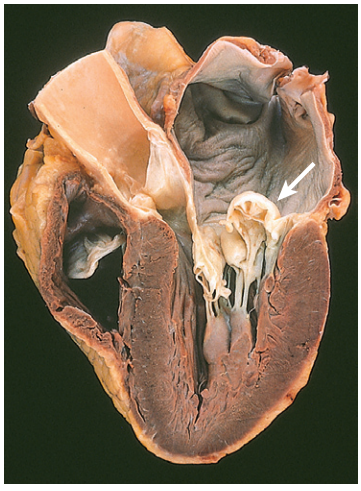

FIG. 37-8 Mitral valve prolapse. In this valvular abnormality, the mitral leaflets have prolapsed back into the left atrium. They also demonstrate hooding *(arrow)*. The left ventricle is on the right.

Genetic Link

Although the etiology of MVP is unknown, some patients have an increased familial incidence. The genetic inheritance is frequently autosomal dominant (see Chapter 13). MVP in this group results from a connective tissue defect affecting only the valve, or as part of Marfan's syndrome or other hereditary conditions that affect the structure of collagen in the body.

Clinical Manifestations

MVP covers a broad range of severity. Most patients are asymptomatic and remain so for their entire lives. About 10% of those with MVP become symptomatic. A characteristic of MVP is a murmur from regurgitation that is louder during systole. MVP does not alter S_1 or S_2 heart sounds. Severe MR is an uncommon but serious complication of MVP.

M-mode and 2-D echocardiography are used to confirm MVP. Dysrhythmias, most commonly premature ventricular contractions, paroxysmal supraventricular tachycardia, and ventricular tachycardia, may cause palpitations, light-headedness, and dizziness. IE may occur in patients with MR associated with MVP.

Patients may or may not have chest pain. The cause of the chest pain is not known. It may be the result of abnormal tension on the papillary muscles. If chest pain occurs, episodes tend to occur in clusters, especially during periods of emotional stress. Dyspnea, palpitations, and syncope may occasionally accompany the chest pain and do not respond to antianginal treatment (e.g., nitrates). β-Adrenergic blockers may be prescribed to control palpitations and chest pain. Encourage the patient to stay hydrated, exercise regularly, and avoid caffeine.

Patients with MVP generally have a benign, manageable course unless problems related to MR develop. No accepted medical therapy appears to delay the need for valve surgery in this group.[20] A teaching plan for patients with MVP is presented in Table 37-11.

AORTIC VALVE STENOSIS

Etiology and Pathophysiology

Congenital **aortic stenosis (AS)** is generally found in childhood, adolescence, or young adulthood. In older adults, AS is a result of RF or degeneration that may have an etiology similar to that of coronary artery disease. It affects 3% of people over

TABLE 37-11 PATIENT & CAREGIVER TEACHING GUIDE

Mitral Valve Prolapse

Include the following information in the teaching plan for a patient with mitral valve prolapse (MVP) and the patient's caregiver.

- Take medications as prescribed (e.g., β-adrenergic blockers to control palpitations, chest pain).
- Adopt healthy eating habits and avoid caffeine because it is a stimulant and may exacerbate symptoms.
- If you use diet pills or other over-the-counter drugs, check for common ingredients that are stimulants (e.g., caffeine, ephedrine), since these can exacerbate symptoms.
- Begin (or maintain) an exercise program to achieve optimal health.
- Contact the health care provider or emergency medical services (EMS) if symptoms develop or worsen (e.g., palpitations, fatigue, shortness of breath, anxiety).

65 years of age.[21] In rheumatic valve disease, fusion of the commissures and secondary calcification cause the valve leaflets to stiffen and retract, resulting in stenosis. If AS occurs due to rheumatic heart disease, mitral valve disease accompanies it. Isolated AS is usually nonrheumatic in origin. The incidence of rheumatic aortic valve disease has been decreasing, but degenerative stenosis is increasing as the population ages.

AS causes obstruction of flow from the left ventricle to the aorta during systole. The effect is left ventricular hypertrophy and increased myocardial oxygen consumption because of the increased myocardial mass. As the disease progresses and compensatory mechanisms fail, reduced CO leads to decreased tissue perfusion, pulmonary hypertension, and HF.

Clinical Manifestations

Symptoms of AS (see Table 37-10) develop when the valve orifice becomes about one third its normal size. Symptoms include the classic triad of angina, syncope, and exertional dyspnea, reflecting left ventricular failure.[21] The prognosis is poor for patients with symptoms and those whose valve obstruction is not fixed. Nitroglycerin is used cautiously to treat angina, since the drug can significantly reduce BP and worsen chest pain. Auscultation of AS typically reveals a normal or soft S_1, a diminished or absent S_2, a systolic murmur, and a prominent S_4.

DRUG ALERT: Nitroglycerin (Nitro-Bid)
- Use cautiously in patients with AS, since significant hypotension may occur.
- Chest pain can worsen due to a decrease in preload and drop in BP.

AORTIC VALVE REGURGITATION

Etiology and Pathophysiology

Aortic regurgitation (AR) may be the result of primary disease of the aortic valve leaflets, the aortic root, or both. Trauma, IE, or aortic dissection can cause acute AR, which constitutes a life-threatening emergency. Chronic AR is generally the result of rheumatic heart disease, a congenital bicuspid aortic valve, syphilis, or chronic rheumatic conditions such as ankylosing spondylitis or reactive arthritis.

AR causes retrograde (backward) blood flow from the ascending aorta into the left ventricle during diastole. This results in volume overload. The left ventricle initially compensates for chronic AR by dilation and hypertrophy. Myocardial contractility eventually declines, and blood volume in the left atrium and pulmonary bed increases. This leads to pulmonary hypertension and right ventricular failure.

Clinical Manifestations

Patients with acute AR have sudden manifestations of cardiovascular collapse (see Table 37-10). The left ventricle is exposed to aortic pressure during diastole. The patient develops severe dyspnea, chest pain, and hypotension indicating left ventricular failure and cardiogenic shock, a life-threatening emergency.

Patients with chronic, severe AR develop a *water-hammer pulse* (a strong, quick beat that collapses immediately). Heart sounds may include a soft or absent S_1, S_3, or S_4; and a soft, high-pitched diastolic murmur.

The patient with chronic AR generally remains asymptomatic for years. Exertional dyspnea, orthopnea, and paroxysmal nocturnal dyspnea develop only after considerable heart dysfunction has occurred (see Table 37-10). Angina occurs less frequently than in AS.

TRICUSPID AND PULMONIC VALVE DISEASE

Etiology and Pathophysiology

Diseases of the tricuspid and pulmonic valves are uncommon, with stenosis occurring more frequently than regurgitation. *Tricuspid stenosis* occurs almost exclusively in patients who have RF or who abuse IV drugs. Tricuspid stenosis results in right atrial enlargement and elevated systemic venous pressures. *Pulmonic stenosis* is almost always congenital and results in right ventricular hypertension and hypertrophy (see Table 37-10).

DIAGNOSTIC STUDIES FOR VALVULAR HEART DISEASE

Diagnosis of valvular heart disease includes data from the patient's history and physical examination and a variety of tests (Table 37-12). A CT scan of the chest with contrast is the gold standard for evaluating aortic disorders.[22] An echocardiogram reveals valve structure, function, and heart chamber size. Transesophageal echocardiography and Doppler color-flow imaging help diagnose and monitor valvular heart disease progression. Real-time 3-D echocardiography can help assess mitral valve and congenital heart disease. Chest x-ray reveals the heart size, altered pulmonary circulation, and valve calcification. An ECG identifies heart rate, rhythm, and any ischemia or ventricular hypertrophy. Cardiac catheterization detects pressure changes in the cardiac chambers, records pressure differences across the valves, and measures the size of valve openings.

TABLE 37-12 COLLABORATIVE CARE

Valvular Heart Disease

Diagnostic

- Echocardiography (Doppler and transesophageal)
- Cardiac catheterization

Collaborative Therapy

Nonsurgical
- Prophylactic antibiotic therapy (see Table 37-2)
  - Rheumatic fever
  - Infective endocarditis (see Table 37-2)
- Sodium restriction
- Medications to treat or control HF
  - Vasodilators* (e.g., nitrates, ACE inhibitors)
  - Positive inotropes (e.g., digoxin)
  - Diuretics
  - β-Adrenergic blockers
- Anticoagulation therapy (see Table 38-10)
- Antidysrhythmia drugs
- Percutaneous transluminal balloon valvuloplasty
- Percutaneous valve replacement

Surgical
- Valve repair
  - Commissurotomy (valvulotomy)
  - Valvuloplasty
  - Annuloplasty
- Valve replacement

*Use cautiously in patients with aortic stenosis.
ACE, Angiotensin-converting enzyme; *HF,* heart failure.

COLLABORATIVE CARE OF VALVULAR HEART DISEASE

Conservative Therapy

An important aspect of conservative management of valvular heart disease is prevention of recurrent RF and IE (see Table 37-12). Treatment depends on the valve involved and disease severity. It focuses on preventing exacerbations of HF, acute pulmonary edema, thromboembolism, and recurrent endocarditis. HF is treated with vasodilators, positive inotropes, β-adrenergic blockers, diuretics, and a low-sodium diet (see Chapter 35).

Anticoagulant therapy prevents and treats systemic or pulmonary emboli. It is used prophylactically in patients with atrial fibrillation. Atrial dysrhythmias are common and treated with calcium channel blockers, β-adrenergic blockers, antidysrhythmia drugs, or electrical cardioversion (see Chapter 36).

Percutaneous Transluminal Balloon Valvuloplasty. An alternative treatment for some patients with valvular heart disease is the *percutaneous transluminal balloon valvuloplasty* (PTBV) procedure. During PTBV, the fused commissures are split open. Balloon valvuloplasty is used for mitral, tricuspid, and pulmonic stenosis, and less often for AS. The procedure is done in the cardiac catheterization laboratory. It involves threading a balloon-tipped catheter from the femoral artery or vein to the stenotic valve. The balloon is inflated in an attempt to separate the valve leaflets. A single- or double-balloon technique may be used for the PTBV procedure. Currently, the use of a single Inoue balloon with hourglass shape allows sequential inflation (Fig. 37-9). This technique is the most popular because it is easy and has good results with few complications (e.g., left ventricular perforation). The PTBV procedure is generally indicated for older adults and for those who are poor surgery candidates. The long-term results of PTBV are similar to those of surgical commissurotomy.

Similar to PTBV, the Sapien Transcatheter Heart Valve (THV) is approved for select patients with AS. The THV is inserted through the femoral artery and moved to the heart. It is released and expanded with a balloon in the location of the aortic valve. This procedure is limited to patients who are eligible for surgery, but who are at high risk for surgical complications (e.g., patients with multiple comorbidities).[23]

Surgical Therapy. The decision for surgical intervention depends on the patient's clinical state using the New York Heart Association classification system for functional disability (see Table 35-5). The type of surgery can be valve repair or valve replacement. The procedure that is used depends on the valves involved, the pathology and severity of the disease, and the patient's clinical condition. All types of valve surgery are palliative, not curative, and patients require lifelong health care.

Valve Repair. Valve repair is usually the surgical procedure of choice. It has a lower operative mortality rate than valve replacement and is often used in mitral or tricuspid valvular heart disease.[24,25] Although valve repair avoids the risks of replacement, it may not restore total valve function.

Mitral *commissurotomy (valvulotomy)* is the procedure of choice for patients with pure mitral stenosis. The less precise closed method of commissurotomy has generally been replaced by the open method. In the *closed procedure* the surgeon inserts a transventricular dilator through the apex of the left ventricle into the opening of the mitral valve. The direct vision procedure, or *open procedure,* requires the use of cardiopulmonary bypass. The surgeon removes thrombi from the atrium and makes a commissure incision. Next, the fused chordae are separated by splitting the papillary muscle and debriding the calcified valve.

Open surgical *valvuloplasty* involves repair of the valve by suturing the torn leaflets, chordae tendineae, or papillary muscles. It is primarily used to treat mitral or tricuspid regurgitation.

Minimally invasive valvuloplasty surgery involves a mini-sternotomy or parasternal approach. It may include robotic and thoracoscopic surgical systems. Results compare with those of

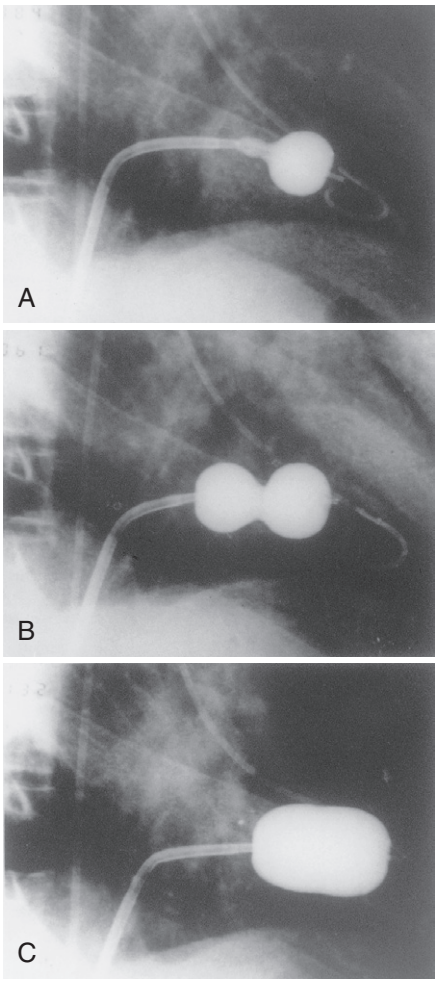

FIG. 37-9 Mitral valvuloplasty performed by the Inoue technique. The catheter is placed in the mitral valve and the distal part of the Inoue balloon inflated **(A).** The balloon is then pulled back in the mitral valve and inflated for 10 to 15 sec under fluoroscopic control **(B)** until the waist of the balloon is no longer visible **(C)** and the balloon falls back into the left atrium.

INFORMATICS IN PRACTICE

Heart Surgery DVD or CD

- Many patients prefer to watch DVDs or listen to CDs instead of reading pamphlets. For a patient facing heart surgery, using a video can be an effective tool to use when teaching the patient and caregiver what to expect before and after the procedure.
- Remember that the DVD or CD is not the teacher.
- Beforehand discuss what the DVD or CD will cover and encourage the patient and caregiver to write down questions or note what they do not understand.
- After the patient and caregiver view or listen to the material, be available to answer any questions they have. Reinforce important information from the DVD or CD.

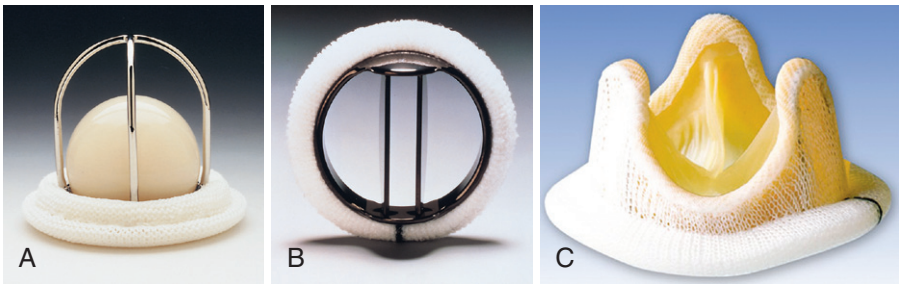

FIG. 37-10 Types of prosthetic heart valves. **A,** Starr-Edwards caged ball valve. **B,** St. Jude bi-leaflet valve. **C,** Carpentier-Edwards porcine valve.

ETHICAL/LEGAL DILEMMAS

Do Not Resuscitate

Situation

J.L., a 68-year-old man, is admitted for a second mitral valve surgery and coronary artery bypass graft surgery. He did not adhere to the treatment plan after his original surgery 7 years ago. You are worried about his future adherence with medications, diet, and exercise. His kidneys are failing and he is on dialysis, making him a high-risk surgical patient. The patient and caregivers want all possible treatment and refuse to discuss Do Not Resuscitate (DNR) orders.

Ethical/Legal Points for Consideration

- Based on their expertise, health care providers have the right to refuse to provide treatment that offers no benefit to the patient.
- Advance directives do not include a DNR order. If the patient is unable to speak for himself or herself, a DNR order can be initiated only by the attending physician or agent and usually depends on evidence of the patient's preferences.
- If there is an advance directive refusing resuscitation, the health care provider is required to act accordingly but is not compelled to enact a DNR without clear direction from the patient or proxy.
- Patient adherence with past treatment plans is not a factor that must be considered in DNR decisions. Many circumstances related to nonadherence are outside the patient's control such as financing, transportation, availability of assistance, and declining physical and medical capabilities.
- If there is disagreement about the patient's treatment plan, a referral can be made to an ethics committee, or the patient can seek treatment from another provider.

Discussion Questions

1. How can a lack of understanding or limited financial resources contribute to nonadherence with the plan of care?
2. What type of information should be provided to a patient and caregiver in discussions about DNR orders? Who should provide this information?
3. Who can initiate a referral to an ethics committee?

the open procedure. In addition, shorter lengths of stay, fewer blood transfusions, less pain, and lower risk of sternal infection and postoperative atrial fibrillation have been reported.[26]

For patients with mitral or tricuspid regurgitation, further valve repair or reconstruction using annuloplasty is an option. *Annuloplasty* involves reconstruction of the annulus, with or without the aid of prosthetic rings (e.g., a Carpentier ring).

Valve Replacement. Valve replacement may be required for mitral, aortic, tricuspid, and occasionally pulmonic valve disease. A wide variety of prosthetic valves are currently available. Desirable valves are nonthrombogenic and durable, and create minimal stenosis. Prosthetic valves are categorized as mechanical or biologic (tissue) valves (Fig. 37-10).

Mechanical valves are manufactured from artificial materials and consist of combinations of metal alloys, pyrolytic carbon, and Dacron. *Biologic valves* are constructed from bovine, porcine, and human (cadaver) heart tissue and usually contain some man-made materials. A "decellularizing" process removes the cadaver cells from the valve. This lowers the risk of immune response and tissue rejection. Biologic valves are asymmetric in shape and produce a more natural pattern of blood flow compared with mechanical valves. Asymmetric mechanical valve prototypes are being tested.[27]

Mechanical prosthetic valves are more durable and last longer than biologic valves. However, they have an increased risk of thromboembolism and require long-term anticoagulation therapy. The main complication of mechanical valves is bleeding from the use of anticoagulants. Biologic valves do not require anticoagulation therapy because of their low thrombogenicity. However, they are less durable and tend to cause early calcification, tissue degeneration, and stiffening of the leaflets. Either type of prosthetic valve can leak and cause endocarditis. Minimally invasive aortic valve replacement uses a transcatheter or transapical approach and is the surgical choice for patients at high risk for traditional surgery.[28,29]

Long-term anticoagulation is needed for those patients with biologic valves who have atrial fibrillation. Some patients with biologic valves or annuloplasty with prosthetic rings may need anticoagulation the first few months after surgery until the suture lines are covered by endothelial cells (endothelialized).

The choice of valves depends on many factors. For example, if a patient cannot take an anticoagulant (e.g., women of childbearing age), a biologic valve is considered. A mechanical valve may be best for a younger patient because it is more durable. For patients over age 65, durability is less important than the risks of bleeding from anticoagulants, so most receive a biologic valve.

NURSING MANAGEMENT VALVULAR DISORDERS

NURSING ASSESSMENT

Table 37-13 presents the subjective and objective data to obtain from an individual with valve disease.

NURSING DIAGNOSES

Nursing diagnoses for the patient with valvular heart disease may include, but are not limited to, the following:

- Decreased CO *related to* valvular incompetence
- Excess fluid volume *related to* fluid retention secondary to valvular-induced HF
- Activity intolerance *related to* insufficient oxygenation secondary to decreased CO and pulmonary congestion

TABLE 37-13 NURSING ASSESSMENT

Valvular Heart Disease

Subjective Data

Important Health Information

Past health history: Rheumatic fever, infective endocarditis; congenital defects, myocardial infarction, chest trauma, cardiomyopathy; syphilis, Marfan's syndrome, streptococcal infections

Functional Health Patterns

Health perception–health management: IV drug abuse; fatigue
Activity-exercise: Palpitations; generalized weakness, activity intolerance; dizziness, fainting; dyspnea on exertion, cough, hemoptysis, orthopnea
Sleep-rest: Paroxysmal nocturnal dyspnea
Cognitive-perceptual: Angina or atypical chest pain

Objective Data

General

Fever

Integumentary

Diaphoresis, flushing, cyanosis, clubbing; peripheral edema

Respiratory

Crackles, wheezes, hoarseness

Cardiovascular

Abnormal heart sounds, including murmurs, S_3, and S_4; dysrhythmias, including atrial fibrillation, premature ventricular contractions; tachycardia; ↑ or ↓ in pulse pressure; hypotension, water-hammer or thready peripheral pulses

Gastrointestinal

Ascites, hepatomegaly, unexplained weight gain

Possible Diagnostic Findings

Cardiomegaly on chest x-ray; ECG abnormalities specific to involved valve; echocardiogram (valve abnormalities and chamber dilation); cardiac catheterization (abnormalities in valves, chamber pressures, cardiac output, and blood flow depending on involved valve)

Additional information on nursing diagnoses is presented in eNursing Care Plan 37-2 available on the website for this chapter.

PLANNING

The overall goals for the patient with valve disease include (1) normal heart function, (2) improved activity tolerance, and (3) an understanding of the disease process and health maintenance measures.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Diagnosing and treating streptococcal infections and providing prophylactic antibiotics for patients with a history of RF are critical to prevent acquired rheumatic valve disease. The patient at risk for endocarditis and any patient with certain cardiac conditions must also receive prophylactic antibiotics (see Table 37-2).

The patient must adhere to prescribed therapies. The individual with a history of RF, endocarditis, and congenital heart disease should know the symptoms of valvular heart disease so early medical treatment may begin.

ACUTE INTERVENTION AND AMBULATORY AND HOME CARE. A patient with progressive valvular heart disease may require outpatient care or hospitalization for management of HF, endocarditis, embolic disease, or dysrhythmias. HF is the most common reason for ongoing medical care.

Your role is to implement therapeutic interventions and evaluate their effects. Design activities considering the patient's limitations. An appropriate exercise plan can increase cardiac tolerance, but activities that cause fatigue and dyspnea should be restricted. Discourage tobacco use. Tell the patient to avoid strenuous physical exercise because damaged valves may not handle the increased CO demand. Your patient's care plan should emphasize conserving energy, setting priorities, and taking planned rest periods. Referral to a vocational counselor may be needed if the patient has a physically or emotionally demanding job.

Perform ongoing cardiac assessments to monitor the effectiveness of medications. Teaching the actions and side effects of drugs is important to increase adherence. The patient must understand the importance of prophylactic antibiotic therapy to prevent IE (see Table 37-2). If the valve disease was caused by RF, ongoing prophylaxis to prevent recurrence is necessary.

When valvular heart disease can no longer be managed medically, surgical intervention is necessary (see Chapter 34 for the care of a patient having heart surgery). The patient who is on anticoagulation therapy (e.g., warfarin [Coumadin]) after surgery for valve replacement must have the international normalized ratio (INR) checked regularly to determine proper dosage and adequacy of therapy. INR values of 2.5 to 3.5 are therapeutic for patients with mechanical valves.

Teaching instructions related to anticoagulation therapy are found in Table 38-14. The patient must know that valve surgery is not a cure, and that regular follow-up with a health care provider is required. Also, teach the patient when to seek medical care. Any manifestations of infection, HF, signs of bleeding, and planned invasive or dental procedures require the patient to notify the health care provider. Finally, encourage patients to obtain and wear a Medic Alert bracelet.

EVALUATION

The expected outcomes for a patient with valvular heart disease are presented in eNursing Care Plan 37-2 available on the website for this chapter.

CARDIOMYOPATHY

Cardiomyopathy (CMP) is a group of diseases that directly affect myocardial structure or function. A diagnosis of CMP is based on the patient's clinical manifestations and noninvasive and invasive diagnostic procedures.

CMP can be classified as primary or secondary. *Primary CMP* refers to those conditions in which the etiology of the disease is idiopathic. The heart muscle in this case is the only part of the heart involved, and other cardiac structures are unaffected. In *secondary CMP* the cause of the myocardial disease is known and is secondary to another disease process. Common causes of secondary CMP are listed in Table 37-14.

Three major types of CMP are dilated, hypertrophic, and restrictive. Each type has its own pathogenesis, clinical presentation, and treatment protocols (Tables 37-15 and 37-16). CMP can lead to cardiomegaly and HF. It is the primary reason that heart transplants are performed.

Takotsubo cardiomyopathy (TCM) is a transient cardiac syndrome that mimics acute coronary syndrome. Patients often are

TABLE 37-14 CAUSES OF CARDIOMYOPATHY

seen with chest pain, have ST segment elevation on ECG, and have elevated cardiac enzyme levels consistent with an MI. However, when the patient undergoes cardiac angiography, there is no significant coronary artery disease. TCM is an acute, stress-related syndrome that is more common in postmenopausal women. Normal cardiac function returns in days or weeks after supportive therapy.[30]

DILATED CARDIOMYOPATHY

Etiology and Pathophysiology

Dilated cardiomyopathy is the most common type of CMP, with a prevalence of 5 to 8 cases per 100,000 people in the United States. It causes HF in 25% to 40% of cases, occurs more frequently in middle-aged African Americans and men, and has a genetic link in 30% of cases. Dilated CMP often follows an infectious myocarditis. Some evidence links dilated CMP

with an autoimmune process.[31] Alcoholic dilated CMP is underrecognized and has unique presentation, treatment, and outcomes.[32] Other common causes of dilated CMP are listed in Table 37-14.

Dilated CMP is characterized by a diffuse inflammation and rapid degeneration of myocardial fibers. This results in ventricular dilation, impaired systolic function, atrial enlargement, and stasis of blood in the left ventricle. SCD from ventricular dysrhythmias is a leading cause of death in idiopathic dilated CMP.[33] *Cardiomegaly* results from ventricular dilation (Fig. 37-11). This causes contractile dysfunction in spite of an enlarged chamber size. In contrast to HF, the walls of the ventricles do not hypertrophy (see eFig. 37-3 on the website for this chapter).

Clinical Manifestations

The signs and symptoms of dilated CMP may develop acutely after a systemic infection or slowly over time. Most people eventually develop HF. Symptoms can include decreased exercise capacity, fatigue, dyspnea at rest, paroxysmal nocturnal dyspnea, and orthopnea. As the disease progresses, the patient may experience dry cough, palpitations, abdominal bloating, nausea, vomiting, and anorexia. Signs can include an abnormal S_3 and/or S_4, dysrhythmias, heart murmurs, pulmonary crackles, edema, weak peripheral pulses, pallor, hepatomegaly, and JVD. Decreased blood flow through an enlarged heart promotes stasis and blood clot formation, and may lead to systemic embolization.

Diagnostic Studies

The diagnosis of dilated CMP is based on the patient's history and exclusion of other causes of HF. Doppler echocardiography is the basis for the diagnosis of dilated CMP in the majority of patients. The chest x-ray may show cardiomegaly with signs of

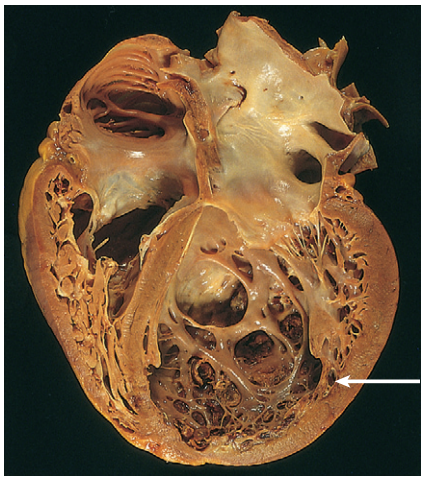

FIG. 37-11 Dilated cardiomyopathy. The dilated left ventricular wall has thinned *(arrow),* and the chamber size and volume are increased.

pulmonary venous hypertension and pleural effusion. The ECG may reveal tachycardia, bradycardia, and dysrhythmias with conduction disturbances. Laboratory studies may show elevated serum levels of b-type natriuretic peptide (BNP) in the presence of HF.

Cardiac catheterization confirms or rules out coronary artery disease, and multiple gated acquisition (MUGA) nuclear scan determines EF. EF less than 20% is associated with a 50% mortality rate within 1 year. Endomyocardial biopsy is done at the time of the right-sided heart catheterization to identify any infectious organisms in heart tissue.

NURSING AND COLLABORATIVE MANAGEMENT DILATED CARDIOMYOPATHY

Interventions focus on controlling HF by enhancing myocardial contractility and decreasing preload and afterload. This is similar to the management of chronic HF. Treatment guidelines are based on the specific stage of disease progression (see Table 35-5). Treatment of patients with Class IV (stage D) HF is more palliative than curative.

Several different types of drugs are available to manage HF (see Table 35-7). Nitrates (e.g., nitroglycerin [Nitrol]) and diuretics (e.g., furosemide [Lasix]) decrease preload, and ACE inhibitors (e.g., captopril [Capoten]) reduce afterload. β-Adrenergic blockers (e.g., metoprolol [Lopressor]) and aldosterone antagonists (e.g., spironolactone [Aldactone]) control the neurohormonal stimulation that occurs in HF. Dysrhythmias are treated with antidysrhythmics (e.g., amiodarone) as indicated (see Chapter 36). Anticoagulation therapy reduces the risk of systemic embolization from clots. These may form in the heart chambers secondary to atrial fibrillation.

Drug and nutritional therapy and cardiac rehabilitation may help (1) alleviate symptoms of HF and (2) improve CO and quality of life. A patient with secondary dilated CMP must be treated for the underlying disease process. For example, the patient with alcohol-related dilated CMP must abstain from all alcohol. (See Chapter 11 for a discussion on addictive behaviors and Chapter 35 for a discussion on HF.)

Unfortunately, dilated CMP does not respond well to therapy, and patients experience multiple episodes of HF. Patients are often hospitalized for infusions of dobutamine (Dobutrex) or milrinone followed by aggressive diuresis. Sometimes these treatments are done on an outpatient basis or in the home under nursing supervision. After treatment, many patients experience an improvement in symptoms that lasts several weeks. The use of statins (e.g., atorvastatin [Lipitor]) in ischemic and idiopathic dilated CMP does increase survival, improve cardiac function, and reduce inflammatory markers[34,35] (see Table 34-5). Additionally, trimetazidine (Vastarel), a metabolic modulator, improves cardiac function and glucose control in diabetic patients with dilated CMP.[36]

Patients also may benefit from nondrug therapies. A ventricular assist device (VAD) allows the heart to rest and recover from acute HF. It may also serve as a bridge to heart transplantation. Additionally, cardiac resynchronization therapy and an implantable cardioverter-defibrillator are used in appropriate patients (see Chapter 35).

The patient with terminal or end-stage CMP may consider heart transplantation. The use of a permanent, implantable VAD, known as destination therapy, is an option for patients with advanced disease who are not candidates for heart transplantation (see Chapter 35). Currently, approximately 50% of heart transplantations are performed for treatment of CMP. Cardiac transplant recipients have a good prognosis. However, donor hearts are difficult to obtain, and many patients with dilated CMP die while awaiting heart transplantation.

Patients with dilated CMP are very ill people with a grave prognosis who need expert nursing care. Observe for signs and symptoms of worsening HF, dysrhythmias, embolic formation, and drug responsiveness. The goals of therapy are to keep the patient at an optimal level of functioning and out of the hospital. Always include caregivers when planning a patient's care. Encourage caregivers to learn cardiopulmonary resuscitation (CPR). Instruct them on when and how to access emergency care.

Home health and hospice nursing can provide the patient and caregiver with palliative care. This includes interventions to maximize and maintain functional status or end-of-life care to prepare for a peaceful death.

HYPERTROPHIC CARDIOMYOPATHY

Etiology and Pathophysiology

Hypertrophic cardiomyopathy is asymmetric left ventricular hypertrophy without ventricular dilation. In one form of the disease the septum between the two ventricles becomes enlarged and obstructs the blood flow from the left ventricle. It is termed *hypertrophic obstructive cardiomyopathy* (HOCMP) or *asymmetric septal hypertrophy* (ASH).

Although hypertrophic CMP can be idiopathic, about half of all cases have a genetic basis characterized by inappropriate myocardial hypertrophy.[37] Early identification is important (see Table 37-14). Hypertrophic CMP occurs less commonly than dilated CMP and is more common in men than in women. It is usually diagnosed in young adults and, most often, in active, athletic individuals. Hypertrophic CMP is the most common cause of SCD in otherwise healthy young people. It accounts for 3% of deaths in young competitive athletes.[38,39]

The four main characteristics of hypertrophic CMP are (1) massive ventricular hypertrophy; (2) rapid, forceful contraction of the left ventricle; (3) impaired relaxation (diastole); and (4) obstruction to aortic outflow (not present in all patients). Ventricular hypertrophy is associated with a thickened intra-

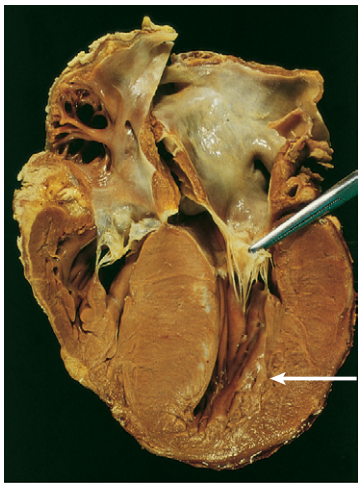

FIG. 37-12 Hypertrophic cardiomyopathy. There is marked left ventricular hypertrophy *(arrow),* and the chamber size and volume are decreased.

ventricular septum and ventricular wall (Fig. 37-12; also see eFig. 37-3 on the website for this chapter). The end result is impaired ventricular filling as the ventricle becomes noncompliant and unable to relax. The primary defect of hypertrophic CMP is diastolic dysfunction from left ventricular stiffness. Decreased ventricular filling and obstruction to outflow can result in decreased CO, especially during exertion.

Clinical Manifestations

Patients with hypertrophic CMP may be asymptomatic or may have exertional dyspnea, fatigue, angina, and syncope. The most common symptom is dyspnea, which is caused by an elevated left ventricular diastolic pressure. Fatigue occurs because of the resultant decrease in CO and in exercise-induced flow obstruction. Angina can occur and is most often caused by the increased left ventricular muscle mass or compression of the small coronary arteries by the hypertrophic ventricular myocardium. The patient may also have syncope, especially during exertion. Syncope is most often caused by an increase in obstruction to aortic outflow during increased activity. This results in decreased CO and cerebrovascular circulation. Syncope can also be caused by dysrhythmias. Common dysrhythmias include supraventricular tachycardia, atrial fibrillation, ventricular tachycardia, and ventricular fibrillation. Any of these dysrhythmias may lead to syncope or SCD (see Chapters 34 and 36).

Diagnostic Studies

Clinical findings on examination may be unremarkable. However, on palpation of the chest the apical impulse can be exaggerated and displaced to the left. Auscultation may reveal an S_4 and a systolic murmur between the apex and the sternal border at the fourth intercostal space. ECG findings usually indicate ventricular hypertrophy, ST-T wave abnormalities, prominent Q waves in the inferior or precordial leads, left axis deviation, and ventricular and atrial dysrhythmias (see Chapter 36).

The echocardiogram is the primary diagnostic tool to confirm hypertrophic CMP. The echocardiogram may also demonstrate wall motion abnormalities and diastolic dysfunction. Cardiac catheterization and nuclear stress testing may also be helpful in diagnosing and guiding the treatment of hypertrophic CMP.

NURSING AND COLLABORATIVE MANAGEMENT HYPERTROPHIC CARDIOMYOPATHY

Goals of care are to improve ventricular filling by reducing ventricular contractility and relieving left ventricular outflow obstruction. These can be done with the use of β-adrenergic blockers (e.g., metoprolol) or calcium channel blockers (e.g., verapamil [Calan]). Digitalis is considered if needed to treat atrial fibrillation. Amiodarone or sotalol (Betapace) are effective antidysrhythmia medications. However, their use does not prevent SCD. For patients at risk for SCD, a cardioverter-defibrillator is needed (see Chapter 36).

AV pacing is helpful for patients with hypertrophic CMP and outflow obstruction. When the ventricles are paced from the apex of the right ventricle, septal depolarization occurs first. This allows the septum to move away from the left ventricular wall and reduces the degree of obstruction of the outflow tract.

Some patients may be candidates for surgical treatment of their hypertrophied septum. The indications for surgery include severe symptoms unresponsive to therapy with marked obstruction to aortic outflow. The surgery is termed a *ventriculomyotomy and myectomy.* It involves cutting into the thickened septal muscle and removing some of the ventricular muscle. Most patients have an improvement in symptoms and exercise tolerance after surgery.

An alternative nonsurgical procedure to reduce symptoms and the left ventricular outflow obstruction is alcohol-induced, percutaneous transluminal septal myocardial ablation (PTSMA). This procedure consists of injecting alcohol into the first septal artery branching off the left anterior descending artery. This causes ischemia and septal wall infarction. Ablation of the septal wall decreases the obstruction to flow, and the patient's symptoms decrease. The procedure improves HF symptoms and exercise capacity 3 months after ablation.[40] Potential complications of PTSMA include conduction disturbances (e.g., heart block) and MI.

Nursing interventions for hypertrophic CMP focus on relieving symptoms, observing for and preventing complications, and providing emotional support. Focus your teaching on helping patients avoid strenuous activity and dehydration. Any activity that causes an increase in systemic vascular resistance (thus increasing the obstruction to forward flow) is dangerous and should be avoided. Rest and elevation of the feet to improve venous return to the heart can manage chest pain in these patients. Vasodilators such as nitroglycerin may worsen the chest pain by decreasing venous return and further increasing obstruction of blood flow from the heart.

RESTRICTIVE CARDIOMYOPATHY

Etiology and Pathophysiology

Restrictive cardiomyopathy is the least common type of CMP. It is a disease of the myocardium that impairs diastolic filling and stretch (see eFig. 37-3 on the website for this chapter). Systolic function remains unchanged. Although the specific etiology of restrictive CMP is unknown, a number of pathologic processes may be involved in its development. Myocardial fibrosis, hypertrophy, and infiltration produce stiffness of the ventricular wall with loss of ventricular compliance. Secondary causes of restrictive CMP include amyloidosis, endocardial fibrosis, sarcoidosis, fibrosis of different etiology, and radiation to the thorax. With restrictive CMP, the ventricles are resistant

to filling and therefore demand high diastolic filling pressures to maintain CO.

Clinical Manifestations and Diagnostic Studies

Classic manifestations of restrictive CMP are fatigue, exercise intolerance, and dyspnea. These occur because the heart cannot increase CO by increasing the heart rate without further compromising ventricular filling. Additional symptoms may include angina, orthopnea, syncope, and palpitations. The patient may have signs of HF, including dyspnea, peripheral edema, weight gain, ascites, hepatomegaly, and JVD.

The chest x-ray may be normal, or it may show cardiomegaly from right and left atrial enlargement. Pleural effusions and pulmonary congestion may be seen in the patient with progression to HF. The ECG may reveal a mild tachycardia at rest. The most common dysrhythmias are supraventricular (atrial fibrillation) or AV block. Echocardiography may reveal a left ventricle that is normal size with a thickened wall, slightly dilated right ventricle, and dilated atria. Endomyocardial biopsy, CT scan, and nuclear imaging may help in the diagnosis.

NURSING AND COLLABORATIVE MANAGEMENT
RESTRICTIVE CARDIOMYOPATHY

Currently, there is no specific treatment for restrictive CMP. Interventions are aimed at improving diastolic filling and the underlying disease process. Treatment includes conventional therapy for HF and dysrhythmias. Heart transplant may also be a consideration. Nursing care is similar to the care of a patient with HF. As in the treatment of patients with hypertrophic CMP, teach the patient to avoid situations that impair ventricular filling and increase systemic vascular resistance, such as strenuous activity and dehydration.

Nursing care of a patient with CMP includes individualized teaching based on the patient's clinical manifestations. All patients with CMP are at risk for IE from any procedure that may cause bacteremia. Instruct the patient on the need for prophylactic antibiotics (see Table 37-2). A general patient and caregiver teaching guide is presented in Table 37-17.

TABLE 37-17 PATIENT & CAREGIVER TEACHING GUIDE

Cardiomyopathy

Include the following information in the teaching plan for a patient with cardiomyopathy and the patient's caregiver.

1. Take all medications as prescribed and regularly follow up with health care provider.
2. Follow a low-sodium diet (if ordered) and read all product labels (food and over-the-counter drugs) for sodium content.
3. Drink six to eight glasses of water a day unless fluids are restricted.
4. Achieve and maintain a reasonable weight and avoid large meals.
5. Avoid alcohol, caffeine, diet pills, and over-the-counter cold medicines that may contain stimulants.
6. Balance activity and rest periods.
7. Avoid heavy lifting or vigorous isometric exercises, and check with health care provider for exercise guidelines.
8. Use stress management techniques: relaxation breathing, guided imagery (see Chapter 7).
9. Report any signs of heart failure to health care provider, including weight gain, edema, shortness of breath, and increased fatigue.
10. Encourage caregivers to learn CPR because of the potential for cardiac arrest (see Appendix A).
11. Access emergency medical services according to the health care provider's instructions.

CPR, Cardiopulmonary resuscitation.

CASE STUDY

Valvular Heart Disease

Jupiterimages/ Photos.com/Thinkstock

Patient Profile

R.B., a 50-year-old white man, is admitted to the hospital for valvular heart disease.

Subjective Data

- Reports past history of IV drug abuse
- Reports current regular alcohol intake approximately 1 pint of whiskey per day
- Complains of chest pain with minimal exertion
- Recently unemployed
- States he is short of breath and cannot sleep lying flat
- States he is tired and irritable all the time
- States he cannot afford medications
- Smokes a pack of cigarettes a day

Objective Data

Physical Examination

- Third heart sound (S_3)
- Loud holosystolic murmur of mitral regurgitation
- Edentulous (secondary to periodontal disease)
- Vital signs: temperature 99.0° F (37.2° C); pulse 110, irregular; respirations 24; BP 104/58

Diagnostic Studies

- ECG shows atrial fibrillation with a rapid ventricular response.
- Chest x-ray reveals pulmonary congestion and cardiomegaly.
- Transesophageal echocardiography shows left atrial and ventricular hypertrophy and mitral and aortic regurgitation.

Discussion Questions

1. Identify the cause and course of R.B.'s disease based on his history and current examination.
2. Differentiate between mitral and aortic regurgitation.
3. What medical treatments or surgical procedures will R.B. probably require as his condition worsens?
4. ***Priority Decision:*** On the basis of the assessment data provided, what are the priority nursing diagnoses?
5. ***Priority Decision:*** Identify the priority nursing interventions for R.B.
6. ***Delegation Decision:*** Identify those tasks that you could delegate to unlicensed assistive personnel (UAP).
7. ***Evidence-Based Practice***: R.B. asks you why he needs to be on "blood thinners" after his valves are replaced.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Assessment of an IV cocaine user with infective endocarditis should focus on which signs and symptoms *(select all that apply)*?
   - **a.** Retinal hemorrhages
   - **b.** Splinter hemorrhages
   - **c.** Presence of Osler's nodes
   - **d.** Painless nodules over bony prominences
   - **e.** Painless erythematous macules on the palms and soles
2. The nurse is caring for a patient with chronic constrictive pericarditis. Which assessment finding reflects a more serious complication of this condition?
   - **a.** Fatigue
   - **b.** Peripheral edema
   - **c.** Jugular venous distention
   - **d.** Thickened pericardium on echocardiography
3. A patient is admitted with myocarditis. While performing the initial assessment, the nurse may find which clinical signs and symptoms *(select all that apply)?*
   - **a.** Angina
   - **b.** Pleuritic chest pain
   - **c.** Splinter hemorrhages
   - **d.** Pericardial friction rub
   - **e.** Presence of Osler's nodes
4. Priority nursing management for a patient with myocarditis includes interventions related to
   - **a.** meticulous skin care.
   - **b.** antibiotic prophylaxis.
   - **c.** tight glycemic control.
   - **d.** oxygenation and ventilation.
5. When teaching a patient about the long-term consequences of rheumatic fever, the nurse should discuss the possibility of
   - **a.** valvular heart disease.
   - **b.** pulmonary hypertension.
   - **c.** superior vena cava syndrome.
   - **d.** hypertrophy of the right ventricle.
6. Which is a priority nursing intervention for a patient during the acute phase of rheumatic fever?
   - **a.** Administration of antibiotics as ordered
   - **b.** Management of pain with opioid analgesics
   - **c.** Encouragement of fluid intake for hydration
   - **d.** Performance of frequent active range-of-motion exercises
7. Which clinical finding would most likely indicate decreased cardiac output in a patient with aortic valve regurgitation?
   - **a.** Reduction in peripheral edema and weight
   - **b.** Carotid venous distention and new-onset atrial fibrillation
   - **c.** Significant pulsus paradoxus and diminished peripheral pulses
   - **d.** Shortness of breath on minimal exertion and a diastolic murmur
8. A patient is diagnosed with mitral stenosis and new-onset atrial fibrillation. Which interventions could the nurse delegate to unlicensed assistive personnel (UAP) *(select all that apply)?*
   - **a.** Obtain and record daily weight.
   - **b.** Determine apical-radial pulse rate.
   - **c.** Observe for overt signs of bleeding.
   - **d.** Obtain and record vital signs, including pulse oximetry.
   - **e.** Teach the patient how to purchase a Medic Alert bracelet.
9. Which diagnostic study best differentiates the various types of cardiomyopathy?
   - **a.** Echocardiography
   - **b.** Arterial blood gases
   - **c.** Cardiac catheterization
   - **d.** Endomyocardial biopsy
10. The nurse is caring for a patient newly admitted with heart failure secondary to dilated cardiomyopathy. Which intervention would be a priority?
    - **a.** Encourage caregivers to learn CPR.
    - **b.** Consider a consultation with hospice for palliative care.
    - **c.** Monitor the patient's response to prescribed medications.
    - **d.** Arrange for the patient to enter a cardiac rehabilitation program.

1. a, b, c, e, 2. c, 3. a, b, d, 4. d, 5. a, 6. a, 7. d, 8. a, c, d, 9. a, 10. c

LEARNING OUTCOMES

1. Relate the major risk factors to the etiology and pathophysiology of peripheral artery disease (PAD).
2. Describe the clinical manifestations, collaborative care, and surgical and nursing management of PAD of the lower extremities.
3. Plan appropriate nursing care for the patient with acute arterial ischemic disorders of the lower extremities.
4. Differentiate the pathophysiology, clinical manifestations, collaborative care, and nursing management of thromboangiitis obliterans (Buerger's disease) and Raynaud's phenomenon.
5. Differentiate the pathophysiology, clinical manifestations, and collaborative care of different types of aortic aneurysms.
6. Select appropriate nursing interventions for a patient undergoing an aortic aneurysm repair.
7. Describe the pathophysiology, clinical manifestations, collaborative care, and nursing management of aortic dissection.
8. Evaluate the risk factors predisposing patients to the development of superficial vein thrombosis and venous thromboembolism (VTE).
9. Differentiate between the clinical characteristics of superficial vein thrombosis and VTE.
10. Compare and contrast the collaborative care and nursing management of patients with superficial vein thrombosis and VTE.
11. Prioritize the key aspects of nursing management of the patient receiving anticoagulant therapy.
12. Relate the pathophysiology and clinical manifestations to the collaborative care of patients with varicose veins, chronic venous insufficiency, and venous leg ulcers.

Virchow's triad, p. 847

Problems of the vascular system include disorders of the arteries, veins, and lymphatic vessels. Arterial disorders are classified as atherosclerotic, aneurysmal, and nonatherosclerotic vascular diseases. Atherosclerotic vascular disease is divided into coronary, cerebral, peripheral, mesenteric, and renal artery disease.[1] This chapter discusses peripheral artery disease; aortic aneurysm and dissection; and venous diseases, specifically venous thromboembolism and chronic venous insufficiency.

PERIPHERAL ARTERY DISEASE

Peripheral artery disease (PAD) involves thickening of artery walls, which results in a progressive narrowing of the arteries

Reviewed by Patricia Hong, RN, MA, Senior Lecturer, University of Washington, School of Nursing, Seattle, Washington; Teri Lynn Kiss, RN, MS, MSSW, CCRN, Director, Medical Unit–2 South and Patient Quality Resources, Fairbanks Memorial Hospital, Fairbanks, Alaska; and Tara McMillan-Queen, RN, MSN, ANP, GNP, Faculty II, Mercy School of Nursing, Charlotte, North Carolina.

GENDER DIFFERENCES

Vascular Disorders

Men

- Thromboangiitis obliterans (Buerger's disease) occurs predominantly in men <40 yr of age.
- Abdominal aortic aneurysms (AAAs) are more common in men than women.
- Men with AAAs are more likely to undergo endovascular aneurysm repair or open aneurysm repair than women.
- Aortic dissection affects men more often than women.

Women

- Women with low lifetime recreational activity are at greater risk for peripheral artery disease (PAD) than similar men.
- Older women experience the classic signs of intermittent claudication less often than men.
- Women with PAD experience faster functional decline and greater mobility loss than men with PAD.
- Raynaud's phenomenon occurs primarily in women between 15 and 40 yr of age.
- Women with AAAs are at higher risk for rupture and have a higher in-hospital mortality rate than men.
- Women undergoing open aneurysm repair and endovascular aneurysm repair have higher 30-day mortality and readmission rates than men of similar age.
- Risk for venous thromboembolism (VTE) is greater in women over age 35 who use tobacco and oral contraceptives or oral hormone therapy (HT), are pregnant or postpartum, or have a family history of VTE.
- Risk for varicose veins is greater in women who use oral contraceptives or HT or are pregnant.

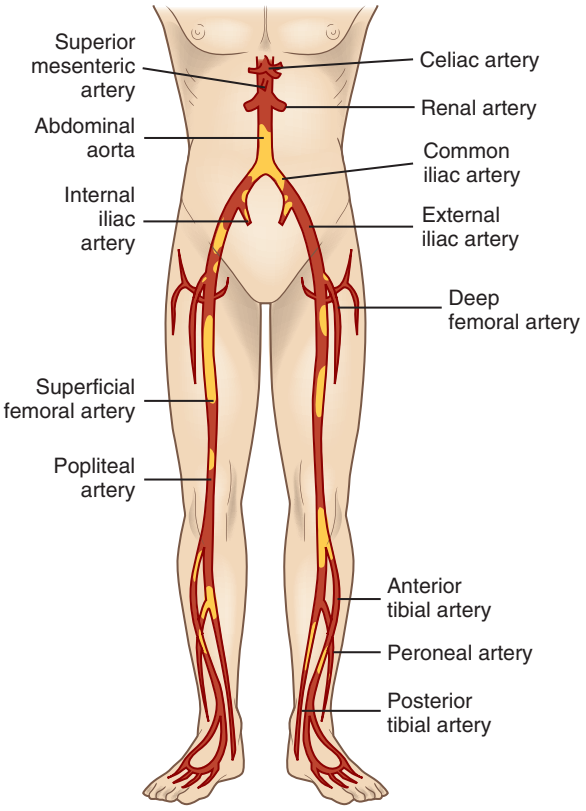

FIG. 38-1 Common anatomic locations of atherosclerotic lesions (shown in *yellow*) of the abdominal aorta and lower extremities.

of the upper and lower extremities. The risk for PAD increases with age; it usually become symptomatic in the sixth to eighth decades of life. In persons with diabetes mellitus, PAD occurs much earlier. About 6% of adults ages 40 years and older and 13% of adults ages 60 years and older have PAD.[2] PAD prevalence is higher in women, and non-Hispanic African Americans.[3,4]

PAD is strongly related to other types of cardiovascular disease (CVD) and their risk factors. Patients with PAD have a significantly higher risk of mortality (in general), CVD mortality, and major coronary events.[5] Thus PAD is a marker of advanced systemic atherosclerosis. Patients with PAD are more likely to have coronary artery disease and/or cerebral artery disease. Unfortunately, most Americans are not familiar with PAD, nor are they aware of PAD risk factors and complications.[6] In general, PAD remains underdiagnosed and undertreated.

Etiology and Pathophysiology

The leading cause of PAD is *atherosclerosis,* a gradual thickening of the *intima* (the innermost layer of the arterial wall) and *media* (middle layer of the arterial wall). This results from the deposit of cholesterol and lipids within the vessel walls and leads to progressive narrowing of the artery. Although the exact cause(s) of atherosclerosis are unknown, inflammation and endothelial injury play a major role (see Chapter 34).

Significant risk factors for PAD include tobacco use, diabetes, hyperlipidemia, elevated C-reactive protein, and uncontrolled hypertension, with the most important being tobacco use. Nicotine is a vasoconstrictor, and tobacco smoke impairs transport and cellular use of oxygen, and increases blood viscosity and homocysteine levels. Other risk factors include family history, hypertriglyceridemia, increasing age, hyperhomocysteinemia, hyperuricemia, obesity, sedentary lifestyle, and stress.[4,7] Women with low lifetime recreational activity are at greater risk for PAD than similar men.[8]

Atherosclerosis more commonly affects certain segments of the arterial tree. These include the coronary (see Chapter 34), carotid (see Chapter 58), and lower extremity arteries. Clinical symptoms occur when vessels are 60% to 75% blocked.

PERIPHERAL ARTERY DISEASE OF THE LOWER EXTREMITIES

Lower extremity PAD may affect the iliac, femoral, popliteal, tibial, or peroneal arteries, or any combination of these arteries (Fig. 38-1). The femoral popliteal area is the most common site in nondiabetic patients. Patients with diabetes tend to develop PAD in the arteries below the knee. In advanced PAD, multiple levels of occlusions are found.

Clinical Manifestations

Generally, the severity of the clinical manifestations depends on the site and extent of the blockage and the amount of collateral circulation. The classic symptom of lower extremity PAD is **intermittent claudication,** which is ischemic muscle pain that is caused by exercise, resolves within 10 minutes or less with rest, and is reproducible.[9] The ischemic pain is a result of the buildup of lactic acid from anaerobic metabolism. Once the patient stops exercising, the lactic acid is cleared and the pain subsides. PAD of the iliac arteries produces claudication in the buttocks and thighs. Calf claudication indicates femoral or popliteal artery involvement. Only about 10% of patients with PAD display the classic symptom of intermittent claudication. Older

TABLE 38-1 COMPARISON OF PERIPHERAL ARTERY AND VENOUS DISEASE

Characteristic	Peripheral Artery Disease	Venous Disease
Peripheral pulses	Decreased or absent	Present, may be difficult to palpate with edema
Capillary refill	>3 sec	<3 sec
Ankle-brachial index	≤0.90	>0.90
Edema	Absent unless leg constantly in dependent position	Lower leg edema
Hair	Loss of hair on legs, feet, toes	Hair may be present or absent
Ulcer		
• Location	Tips of toes, foot, or lateral malleolus	Near medial malleolus
• Margin	Rounded, smooth, looks "punched out"	Irregularly shaped
• Drainage	Minimal	Moderate to large amount
• Tissue	Black eschar or pale pink granulation	Yellow slough or dark red, "ruddy" granulation
Pain	Intermittent claudication or rest pain in foot Ulcer may or may not be painful	Dull ache or heaviness in calf or thigh Ulcer often painful
Nails	Thickened; brittle	Normal or thickened
Skin color	Dependent rubor, elevation pallor	Bronze-brown pigmentation Varicose veins may be visible
Skin texture	Thin, shiny, taut	Skin thick, hardened, and indurated
Skin temperature	Cool, temperature gradient down the leg	Warm, no temperature gradient
Dermatitis	Rarely occurs	Frequently occurs
Pruritus	Rarely occurs	Frequently occurs

women experience it less often than men.[10] If PAD involves the internal iliac arteries, erectile dysfunction may result.

Paresthesia, or numbness or tingling, in the toes or feet may result from nerve tissue ischemia. True peripheral neuropathy occurs more often in patients with diabetes (see Chapter 49) and in those with long-standing ischemia. Neuropathy produces severe shooting or burning pain in the extremity. It does not follow particular nerve roots and may be present near ulcerated areas. Gradual, reduced blood flow to neurons produces loss of both pressure and deep pain sensations. Thus patients may not notice lower extremity injuries.

The limb's physical appearance provides important information about blood flow. The skin becomes thin, shiny, and taut, and hair loss occurs on the lower legs. Pedal, popliteal, or femoral pulses are diminished or absent. Pallor (blanching of the foot) develops in response to leg elevation *(elevation pallor).* Conversely, *reactive hyperemia* (redness of the foot) develops when the limb is in a dependent position *(dependent rubor)* (see Table 38-1).

As PAD progresses and involves multiple arterial segments, continuous pain develops at rest. *Rest pain* most often occurs in the foot or toes and is aggravated by limb elevation. Rest pain occurs when blood flow is insufficient to meet basic metabolic requirements of the distal tissues. Rest pain occurs more often at night because cardiac output tends to drop during sleep and the limbs are at the level of the heart. Patients often try to achieve pain relief by dangling the leg over the side of the bed or sleeping in a chair. This allows gravity to maximize blood flow.

The patient with chronic rest pain, ulceration, or gangrene has *critical limb ischemia*. Critical limb ischemia may lead to amputation if untreated. Every attempt is made to save the limb with surgical or endovascular revascularization. If a patient is not a candidate for revascularization and/or if revascularization is not technically possible, medical treatment is required.[11]

Complications

Lower extremity PAD progresses slowly. Prolonged ischemia leads to atrophy of the skin and underlying muscles. Even minor trauma to the feet (e.g., stubbing one's toe, blister from shoes) can result in delayed healing, wound infection, and tissue necrosis, especially in the diabetic patient. Arterial (ischemic) ulcers most often occur over bony prominences on the toes, feet, and lower legs (Table 38-1). Nonhealing arterial ulcers and gangrene are the most serious complications. Amputation may be needed if adequate blood flow is not restored or if severe infection occurs. If PAD is present for an extended period, collateral circulation may prevent gangrene of the extremity. Uncontrolled pain and severe, spreading infection are indicators that an amputation is needed in individuals who are not candidates for revascularization.

Diagnostic Studies

Various tests can assess blood flow and outline the vascular system (Table 38-2). Doppler ultrasound with duplex imaging maps blood flow throughout the entire region of an artery. When palpation of a peripheral pulse is difficult because of severe PAD, the Doppler ultrasound can determine the degree of blood flow. A palpable pulse and a Doppler pulse are not equivalent, and the terms are not interchangeable. *Segmental blood pressures* (BPs) are obtained (using Doppler ultrasound and a sphygmomanometer) at the thigh, below the knee, and at ankle level while the patient is supine. A drop in segmental BP of greater than 30 mm Hg suggests PAD. Angiography and magnetic resonance angiography delineate the location and extent of PAD (see Table 32-6).

The *ankle-brachial index* (ABI) is a PAD screening tool. It is performed using a hand-held Doppler. The ABI is calculated by dividing the ankle systolic BPs by the higher of the left and right brachial systolic BPs. PAD guidelines recommend uniform reporting of ABI results[12] (Table 38-3). In very elderly patients and those with diabetes, the arteries often are calcified and noncompressible. This results in a falsely elevated ABI. ABI measurement is not recommended immediately after revascularization surgery or on distal bypass grafts because of the risk of graft thrombosis.[13]

Collaborative Care

Table 38-2 summarizes the collaborative care for a patient with PAD.

Risk Factor Modification. The first treatment goal in treating PAD is to reduce CVD risk factors in all patients with PAD regardless of the severity of symptoms.[14] Risk factors need to be

TABLE 38-2 COLLABORATIVE CARE

Peripheral Artery Disease

Diagnostic

- Health history and physical examination, including palpation of peripheral pulses
- Doppler ultrasound studies
- Segmental blood pressures
- Ankle-brachial index (see Table 38-3)
- Duplex imaging
- Angiography
- Magnetic resonance angiography

Collaborative Therapy

- Cardiovascular disease risk factor modification
  - Tobacco cessation
  - Regular physical exercise
  - Achieve or maintain ideal body weight
  - Follow Dietary Approaches to Stop Hypertension (DASH) diet (see eTable 33-1)
  - Tight glucose control in diabetics
  - Tight blood pressure control
  - Treatment of hyperlipidemia and hypertriglyceridemia (see Table 34-5)
  - Antiplatelet agent (aspirin or clopidogrel [Plavix])
  - Angiotensin-converting enzyme inhibitors (see Table 33-7)
- Treatment of claudication symptoms
  - Structured walking or exercise program
  - Cilostazol (Pletal)
- Nutrition therapy
- Proper foot care (see Table 49-21)
- Percutaneous transluminal balloon angioplasty with or without stent
- Percutaneous transluminal atherectomy
- Percutaneous transluminal cryoplasty
- Peripheral artery bypass surgery
- Patch graft angioplasty, often in conjunction with bypass surgery
- Endarterectomy (for localized stenosis but rarely done)
- Thrombolytic therapy or mechanical clot extraction therapy (for acute ischemia only)
- Sympathectomy (for pain management only)
- Amputation

TABLE 38-3 INTERPRETATION OF ANKLE-BRACHIAL INDEX RESULTS

Ankle-Brachial Index (ABI)	Clinical Significance
≥1.40	Noncompressible arteries
1.00-1.40	Normal ABI
0.91-0.99	Borderline ABI
≤0.90	Abnormal ABI
Classification of PAD Severity	
0.90-0.71	Mild PAD
0.71-0.41	Moderate PAD
≤40	Severe PAD

PAD, Peripheral artery disease.

modified with both drug therapy and lifestyle changes (see Tables 34-3 to 34-5).

Tobacco cessation is essential to reduce the risk of CVD events, PAD progression, and death. This is a complex and difficult process with a high incidence of smoking relapse. Comprehensive tobacco cessation strategies are recommended (see Tables 11-4 to 11-6).

Diabetes is a major risk factor for PAD and increases the risk of amputation in these patients. It is recommended that diabetic patients maintain a glycosylated hemoglobin (Hb A1C) below 7.0% and, optimally, as near as possible to 6.0%.[15] (Chapter 49 discusses diabetes mellitus.)

Aggressive lipid management is essential for all patients with PAD.[14] Both dietary interventions and drug therapy are needed. Statins (e.g., simvastatin [Zocor]) lower low-density lipoprotein (LDL) and triglyceride levels and reduce CVD morbidity and mortality risks.[16] Unfortunately, as many as 70% of people with PAD do not take a statin and have elevated LDL levels.[2]

Hypertension is a well-known risk factor for PAD progression, as well as other CVD events (e.g., stroke, myocardial infarction [MI], heart failure). Guidelines for the management of hypertension in persons with PAD include BP less than 140/90 mm Hg.[2,14] In PAD patients with diabetes or renal insufficiency, BP less than 130/80 mm Hg is recommended.[15]

Initial antihypertensive therapy includes thiazides and angiotensin-converting enzyme (ACE) inhibitors (e.g., ramipril [Altace]). Lifestyle changes are encouraged and include reducing dietary sodium and following the Dietary Approaches to Stop Hypertension (DASH) diet. (Chapter 33 discusses hypertension.)

Drug Therapy. Antiplatelet agents are considered critical for reducing the risks of CVD events and death in PAD patients. Oral antiplatelet therapy should include 75 to 100 mg/day of aspirin for patients with asymptomatic PAD and 75 to 325 mg/day of aspirin for patients with symptomatic PAD.[11,12] Aspirin-intolerant patients may take clopidogrel (Plavix) daily.

Combination antiplatelet therapy with aspirin and clopidogrel is not typically recommended, but may be used in symptomatic PAD patients at high risk for CVD events.[12] Anticoagulants (e.g., warfarin [Coumadin]) are not recommended for the prevention of CVD events in PAD patients.

DRUG ALERT: Clopidogrel (Plavix) and Omeprazole (Prilosec)

- Antiplatelet effect of clopidogrel is reduced by about half when given with omeprazole.
- This increases the risk of MI and stroke.

Two drugs are available to treat intermittent claudication: cilostazol (Pletal) and pentoxifylline (Trental). Cilostazol, a phosphodiesterase inhibitor, inhibits platelet aggregation and increases vasodilation. It is recommended as first-line drug therapy for patients with intermittent claudication who do not respond to exercise therapy or stop using tobacco.[11] Cilostazol does not reduce CVD morbidity and mortality risks, so antiplatelet therapy is also needed.

DRUG ALERT: Cilostazol (Pletal)

- Contraindicated in patients with heart failure of any severity.

Exercise Therapy. The primary nondrug treatment for intermittent claudication is tobacco cessation in combination with a formal, supervised exercise training program. Exercise improves walking ability. Lack of exercise and impaired walking ability in PAD patients is related to low quality of life.[17] Encouragement of participation in exercise is particularly important for women with PAD, since women experience faster functional decline and greater mobility loss than men with PAD.[17] In addition, women with PAD are more likely to have a history of limited recreational activities.[8]

Walking is the most effective exercise for PAD patients. A supervised PAD rehabilitation program is an effective means of improving exercise performance. Such programs typically include exercise for 30 to 60 minutes/day, 3 to 5 times/week, for 3 to 6 months. Supervised treadmill exercise training improves walking performance and quality of life in PAD patients, whether or not they have claudication.[17]

A home exercise program is an effective alternative to supervised rehabilitation. Encourage slow, progressive physical activity after a warm-up period. Instruct the patient to walk to the point of discomfort, stop and rest, and then resume walking until the discomfort recurs. Walking should be done for 30 to 40 minutes/day, 3 to 5 times/week. An exercise therapy program should also be implemented in PAD patients after surgical interventions (discussed later in this chapter).

Nutritional Therapy. Teach PAD patients to adjust their dietary intake so that their body mass index (BMI) is less than 25 kg/m^2 and their waist circumference is less than 40 inches for men and less than 35 inches for women.[18] Recommend a diet high in fruits, vegetables, and whole grains and low in cholesterol, saturated fat, and salt (see Chapters 34 and 35).

Complementary and Alternative Therapies. Patients taking antiplatelet agents, nonsteroidal antiinflammatory drugs (NSAIDs) (e.g., ibuprofen [Motrin]), and anticoagulants (e.g., warfarin) should consult with their health care provider before taking any dietary or herbal supplements because of potential interactions and bleeding risks[19] (see the Complementary & Alternative Therapies box on p. 851).

Care of the Leg With Critical Limb Ischemia. **Critical limb ischemia** is a condition characterized by chronic ischemic rest pain lasting more than 2 weeks, arterial leg ulcers, or gangrene of the leg as a result of PAD.[12] Optimal therapy is revascularization via bypass surgery. If this is not feasible, percutaneous transluminal angioplasty (PTA) is recommended in patients with a life expectancy of 2 years or less.[12] Patients with critical limb ischemia who are not candidates for surgery or PTA may be treated with prostanoids (e.g., iloprost [Ventavis]). These drugs may decrease rest pain and improve ulcer healing. Patients with critical limb ischemia should continue CVD risk factor reduction and antiplatelet therapy to reduce the risk of a CVD event.

Conservative management of critical limb ischemia includes protecting the extremity from trauma, decreasing ischemic pain, preventing and controlling infection, and improving perfusion. Carefully inspect, cleanse, and lubricate both feet to prevent cracking of the skin and infection. Avoid soaking the patient's feet to prevent skin *maceration* (or breakdown). If ulceration is present, keep the affected foot clean and dry. Cover any ulcers with a dry, sterile dressing to maintain cleanliness. Deep ulcers can be treated with a variety of wound care products, but healing is unlikely without increased blood flow.

Encourage the patient to select soft, roomy, and protective footwear and avoid extremes of heat and cold. Keep the patient's heels free of pressure. You can do this by placing a pillow under the calves so that the heels are off the mattress. Commercially available devices can also provide heel protection. Administering opioid analgesics and placing the bed in the reverse Trendelenburg position may control pain and increase perfusion to the lower extremities.

Spinal cord stimulation may be helpful in managing pain and preventing amputation in patients with critical limb ischemia. Other promising strategies include gene therapy and endothelial progenitor cell therapy to stimulate blood vessel growth *(angiogenesis)*.[20]

Interventional Radiology Catheter-Based Procedures. Interventional radiology catheter-based procedures are alternatives to open surgical approaches for treatment of lower extremity PAD. These procedures take place in a catheterization laboratory rather than in an operating room. Determining which intervention to use depends on blockage location and lesion type and severity.

All these procedures are similar to angiography in that they involve the insertion of a specialized catheter into the femoral artery. The *percutaneous transluminal angioplasty* (PTA) procedure uses a catheter that contains a cylindric balloon at the tip. The end of the catheter is moved to the narrowed (stenotic) area of the artery. The balloon is then inflated, compressing the atherosclerotic intimal lining.[21]

Stents, expandable metallic devices, are positioned within the artery immediately after the balloon angioplasty is done. The stent acts as a scaffold to keep the artery open. The stents may be covered with Dacron or a drug-eluting agent (e.g., paclitaxel) to reduce restenosis by limiting the amount of new tissue growth in the stent.

Atherectomy is the removal of the obstructing plaque. A directional atherectomy device uses a high-speed cutting disk that cuts long strips of the atheroma. Laser atherectomy uses ultraviolet energy to break up the atheroma. Orbital or rotational atherectomy catheters have a diamond-coated tip that rotates at a high speed (similar to a dentist drill). These crush the calcium within the atheroma into particles smaller than a blood cell.

Cryoplasty combines two procedures: PTA and cold therapy. A specialized balloon is filled with liquid nitrous oxide, which changes from liquid to gas as it enters the balloon. Expansion of the gas results in cooling to 14° F (–10° C). The cold limits restenosis by reducing smooth muscle cell activity.[22] Preprocedure and postprocedure nursing care is the same as for a diagnostic angiography. Antiplatelet agents are needed after the procedure to reduce the risk of restenosis. Long-term, low-dose aspirin therapy (75 to 100 mg/day) or clopidogrel (75 mg/day) is recommended. Restenosis rates depend on the procedure performed, lesion type and length, and target vessel characteristics. Immediate postprocedure success rates are high (greater than 95%) for iliac and femoral interventions.[23]

Surgical Therapy. Various surgical approaches can be used to improve blood flow beyond a blocked artery. The most common is peripheral artery bypass surgery with an autogenous (native) vein or synthetic graft to bypass, or carry blood around, the lesion (Fig. 38-2). Synthetic grafts typically are used for long bypasses such as an axillary-femoral bypass. When a person's own vein is not available, human umbilical vein or a composite sequential bypass graft (native vein plus synthetic graft) is an alternative.[14] PTA with stenting may also be used in combination with bypass surgery. Other surgical options include *endarterectomy* (opening the artery and removing the obstructing plaque) and *patch graft angioplasty* (opening the artery, removing plaque, and sewing a patch to the opening to widen the lumen).

Amputation may be required if tissue necrosis is extensive, gangrene or osteomyelitis develops, or all major arteries in the limb are blocked, precluding the possibility of successful surgery.[20] Every effort is made to preserve as much of the limb as possible to improve the potential for rehabilitation. (Amputation is discussed in Chapter 63.)

NURSING MANAGEMENT LOWER EXTREMITY PERIPHERAL ARTERY DISEASE

NURSING ASSESSMENT

Table 38-4 presents subjective and objective data that you should obtain from a patient with PAD.

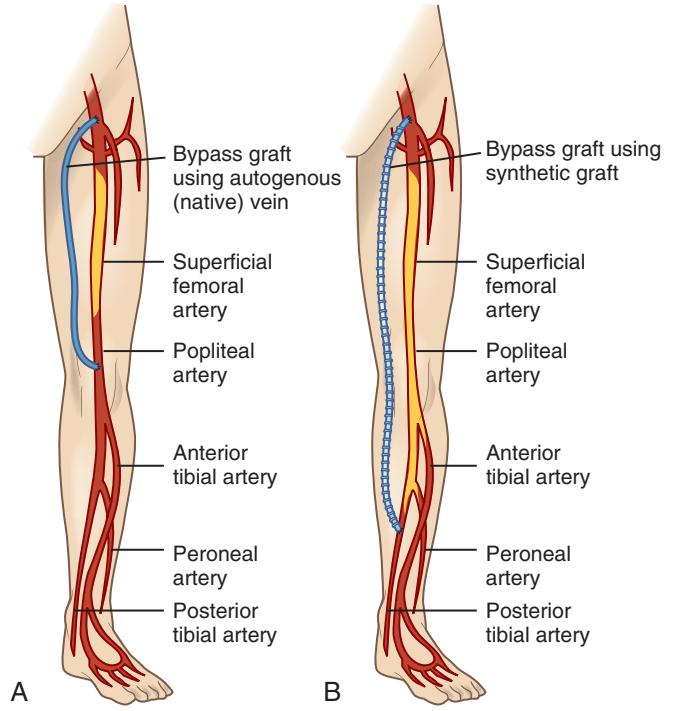

FIG. 38-2 **A,** Femoral-popliteal bypass graft around an occluded superficial femoral artery. **B,** Femoral–posterior tibial bypass graft around occluded superficial femoral, popliteal, and proximal tibial arteries.

NURSING DIAGNOSES

Nursing diagnoses for the patient with PAD may include, but are not limited to, the following:

- Ineffective peripheral tissue perfusion *related to* deficient knowledge of contributing factors
- Activity intolerance *related to* imbalance between oxygen supply and demand
- Ineffective self-health management *related to* lack of knowledge of disease and self-care measures

Additional information on nursing diagnoses for the patient with PAD of the lower extremities is presented in eNursing Care Plan 38-1 on the website for this chapter.

PLANNING

The overall goals for the patient who has lower extremity PAD include (1) adequate tissue perfusion; (2) relief of pain; (3) increased exercise tolerance; and (4) intact, healthy skin on the extremities.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Assess the patient for CVD risk factors and provide instructions on how to control them (see Tables 34-2 to 34-4). Also teach diet modification to reduce the intake of cholesterol, saturated fat, and refined sugars; proper care of the feet; and avoidance of injury to the extremities. Encourage patients with positive family histories of cardiac, diabetic, or vascular disease to obtain regular follow-up care.

ACUTE INTERVENTION. After surgical or radiologic intervention, the patient is moved to a recovery area for observation. Check the operative extremity every 15 minutes initially and then hourly for color, temperature, capillary refill, presence of peripheral pulses, and sensation and movement. Loss of palpable pulses or a change in the Doppler sound over a pulse requires immediate notification of the physician or radiologist and prompt intervention. Postoperative ABI measurements are not recommended as they place the patient at risk for graft thrombosis.[13] Compare all assessment findings with the patient's baseline and with findings in the opposite limb.

Many PAD patients have a history of chronic ischemic rest pain and may have developed a tolerance to opioids. Thus aggressive pain management may be needed postoperatively.

After the patient leaves the recovery area, continue to monitor perfusion to the extremities. Assess for potential complications such as bleeding, hematoma, thrombosis, embolization, and compartment syndrome. A dramatic increase in pain, loss of previously palpable pulses, extremity pallor or cyanosis, decreasing ABIs, numbness or tingling, or a cold extremity suggests blockage of the graft or stent. Report these findings to the physician immediately. Women, particularly African American women, experience more graft failure and amputation after lower extremity bypass surgery than men.[6]

Avoid placing the patient in a knee-flexed position except for exercise. Turn the patient and position frequently with pillows to support the incision. On postoperative day 1, assist the patient out of bed several times daily. Discourage prolonged sitting with leg dependency, since it may cause pain and edema, increase the risk of venous thrombosis, and place stress on the suture lines. If edema develops, position the patient supine and

TABLE 38-4 NURSING ASSESSMENT

Peripheral Artery Disease

Subjective Data

Important Health Information

Past health history: Tobacco use, diabetes mellitus, hypertension, hyperlipidemia, hypertriglyceridemia, hyperuricemia, impaired renal function, obesity; ↑ high-sensitivity C-reactive protein, homocysteine, or lipoprotein (a) [Lp(a)] levels; positive family history, sedentary lifestyle, stress

Functional Health Patterns

Health perception–health management: Family history of cardiovascular disease; tobacco use, including exposure to environmental smoke

Nutritional-metabolic: High sodium, saturated fat, and cholesterol intake; elevated Hb A1C

Activity-exercise: Exercise intolerance

Cognitive-perceptual: Buttock, thigh, or calf pain that is precipitated by exercise and that subsides with rest (intermittent claudication) or progresses to pain at rest; burning pain in forefeet and toes at rest; numbness, tingling, sensation of cold in legs or feet; progressive loss of sensation and deep pain in extremities

Sexuality-reproductive: Erectile dysfunction

Objective Data

Integumentary

Loss of hair on legs and feet; thick toenails; pallor with elevation; dependent rubor; thin, cool, shiny skin with muscle atrophy; skin breakdown and arterial ulcers, especially over bony areas; gangrene

Cardiovascular

Decreased or absent peripheral pulses; feet cool to touch; capillary refill >3 sec; bruits may be present at pulse sites

Neurologic

Mobility or sensation impairment

Possible Diagnostic Findings

Arterial stenosis evident with duplex imaging, ↓ Doppler pressures, ↓ ankle-brachial index, angiography indicative of peripheral atherosclerosis

elevate the leg above heart level. Occasionally, elastic compression stockings are used to help control leg edema. Walking even short distances is desirable. The use of a walker may be helpful, especially in frail, older patients.

Surgical site infection (SSI) after lower extremity revascularization occurs in about 11% of cases. Women develop SSIs more often than men. Careful postoperative assessment and wound care are important. SSIs are associated with early graft loss, reoperation, and sepsis.[24] If no complications occur, discharge can be anticipated 3 to 5 days after surgery.

AMBULATORY AND HOME CARE. Assess for CVD risk factors and be alert for opportunities to teach health promotion strategies to patients and their caregivers (see Chapters 4 and 34). Continued tobacco use dramatically decreases the long-term patency rates of grafts and stents and increases the risk of an MI or stroke. Long-term therapy with aspirin or clopidogrel is recommended for patients after surgery. Patients having distal peripheral bypass surgery (i.e., below the knee) using synthetic graft materials are given dual antiplatelet therapy (clopidogrel plus aspirin) for 1 year, followed by lifelong single antiplatelet therapy.

Encourage supervised exercise training after a successful revascularization. Explain that exercise improves a number of CVD risk factors, including hypertension, hyperlipidemia, obesity, and glucose levels. Teach foot care to all patients with PAD. Meticulous foot care is especially important in the diabetic patient with PAD (see Table 49-21). Diabetic neuropathy increases the patient's risk for injury and results in delay in seeking treatment. Instruct patients to inspect their legs and feet daily for mottling, changes in skin color or texture, and reduction in hair growth. Show patients how to check skin temperature and capillary refill and to palpate pulses. Emphasize that they must report any changes in these findings or the development of ulceration or inflammation to their health care provider. Thick or overgrown toenails and calluses are potentially serious and require regular attention by a health care provider (e.g., podiatrist). Patients who have poor eyesight, back problems, obesity, or arthritis may need help with foot care. Encourage patients to wear clean, all-cotton or all-wool socks and comfortable shoes with rounded (not pointed) toes and soft insoles. Tell patients to lace shoes loosely and to break in new shoes gradually (Table 38-5).

TABLE 38-5 PATIENT & CAREGIVER TEACHING GUIDE

Peripheral Artery Bypass Surgery

Include the following information in the teaching plan for a patient undergoing peripheral artery bypass surgery and the patient's caregiver.

1. Reduce risk factors by stopping the use of all tobacco products, controlling blood glucose levels (if diabetic) and blood pressure, lowering cholesterol and triglyceride levels, achieving or maintaining ideal body weight, and exercising regularly.
2. Provide rationales, basic action, and anticipated duration of medications such as antiplatelets, antihypertensives, lipid-lowering therapy, and pain medication.
3. Eat healthy—it is essential to recovery. Drink plenty of fluids, eat a well-balanced diet (e.g., foods high in protein, vitamins C and A, and zinc; high-fiber foods; fresh fruits and vegetables), eat fewer high-fat foods, and reduce salt intake.
4. Participate in a supervised exercise program or take a daily walk. In the beginning, take several short walks a day and rest between activities. Gradually increase your walking to 30 to 40 min/day, 3 to 5 days/wk.
5. Care for feet and legs. Inspect feet and wash them daily. Wear clean cotton or wool socks and well-fitting shoes. File toenails straight across. Avoid sitting with legs crossed, extreme hot and cold temperatures, and prolonged standing.
6. Follow routine postoperative wound care that includes keeping incision clean and dry; do not disturb Steri-Strips (if present).
7. Monitor for signs and symptoms of impaired healing or infection of the leg incision, and notify health care provider if any of the following occurs:
   - Prolonged drainage or pus from the incision
   - Increased redness, warmth, pain, or hardness along incision
   - Separation of wound edges
   - Temperature >100° F (37.8° C)
8. Keep all follow-up appointments with health care provider.
9. Notify health care provider immediately of increased leg or foot pain or a change in the color or temperature of leg or foot.

EVALUATION

The expected outcomes for the patient with PAD of the lower extremities include

- Adequate peripheral tissue perfusion
- Increased activity tolerance
- Knowledge of disease and treatment plan

Additional information on the expected outcomes for the patient with PAD of the lower extremities are presented in eNursing Care Plan 38-1 (available on the website for this chapter).

ACUTE ARTERIAL ISCHEMIC DISORDERS

Etiology and Pathophysiology

Acute arterial ischemia is a sudden interruption in the arterial blood supply to a tissue, an organ, or an extremity that, if left untreated, can result in tissue death. It is caused by embolism, thrombosis of a preexisting atherosclerotic artery, or trauma. *Embolization* of a thrombus from the heart is the most frequent cause of acute arterial occlusion. Heart conditions in which thrombi can develop include infective endocarditis, mitral valve disease, atrial fibrillation, cardiomyopathies, and prosthetic heart valves. Noncardiac sources of emboli include aneurysms, ulcerated atherosclerotic plaque, recent endovascular procedures, and venous thrombi.

The thrombi become dislodged and may travel anywhere in the systemic circulation if they originate in the left side of the heart. Most emboli block an artery of the lower extremity in areas where vessels branch (e.g., iliofemoral, popliteal, tibial) or there is atherosclerotic narrowing. Sudden local thrombosis may occur at the site of an atherosclerotic plaque. Hypovolemia (e.g., shock), hyperviscosity (e.g., polycythemia), and hypercoagulability (e.g., chemotherapy) predispose an individual to thrombotic arterial occlusion.[25]

Traumatic injury to the extremity itself may cause partial or total blockage. Acute arterial occlusion may also develop as a result of arterial dissection in the carotid artery or aorta or as a result of a procedure-related arterial injury (e.g., after angiography).

Clinical Manifestations

Clinical manifestations of acute arterial ischemia include the *"six Ps": pain, pallor, pulselessness, paresthesia, paralysis,* and *poikilothermia* (adaptation of the limb to the environmental temperature, most often cool). Without immediate intervention, ischemia may progress to tissue necrosis and gangrene within a few hours. If you detect these signs, immediately notify

the physician. Paralysis is a late sign of acute arterial ischemia and signals the death of nerves supplying the extremity. Foot drop occurs as a result of nerve damage. Because nerve tissue is extremely sensitive to hypoxia, limb paralysis or ischemic neuropathy may persist even after revascularization.

Collaborative Care

Early treatment is essential to keep the affected limb viable during acute arterial ischemia. Anticoagulant therapy with IV unfractionated heparin (UH) is started to prevent thrombus growth and inhibit further embolization.[11] In patients undergoing embolectomy, UH should be followed by long-term anticoagulation with warfarin (see discussion of other anticoagulant options later in this chapter).

To restore blood flow, the thrombus is removed as soon as possible. Options consist of surgical thrombectomy (recommended procedure), percutaneous catheter-directed thrombolytic therapy, percutaneous mechanical thrombectomy with or without thrombolytic therapy, or surgical bypass.

If surgical thrombectomy is not possible, percutaneous catheter-directed thrombolytic therapy using tissue plasminogen activator (tPA [alteplase]) or urokinase (Kinlytic) is recommended. A catheter is inserted into the femoral artery and moved to the site of the clot, and the thrombolytic drug is infused. Thrombolytic agents work by directly dissolving the clot over a period of 24 to 48 hours. (Chapter 34 discusses thrombolytic therapy.) Another type of catheter may act as a mechanical thrombectomy device, meaning it is also designed to remove or fragment the thrombus.[26] Surgical revascularization may be used in a patient with trauma (e.g., laceration of the artery) or with significant arterial blockage. Amputation is reserved for patients with ischemic rest pain and tissue loss in whom limb salvage is not possible. If the patient remains at risk for further embolization from a persistent source (e.g., chronic atrial fibrillation), long-term oral anticoagulation is recommended to prevent further acute arterial ischemic episodes[27] (see Table 38-10 later in this chapter).

THROMBOANGIITIS OBLITERANS

Thromboangiitis obliterans (Buerger's disease) is a nonatherosclerotic, segmental, recurrent inflammatory disorder of the small- and medium-sized arteries and veins of the upper and lower extremities. Rarely, systemic manifestations of the disease may involve cerebral, coronary, mesenteric, pulmonary, and/or renal arteries. The disease occurs mostly in young men (less than 45 years of age) with a long history of tobacco and/or marijuana use and chronic periodontal infection, but without other CVD risk factors (e.g., hypertension, hyperlipidemia, diabetes).[28]

In the acute phase of Buerger's disease, an inflammatory thrombus forms and blocks the vessel. Over time, the thrombus becomes more organized and the inflammation subsides.[28] During the chronic phase, thrombosis and fibrosis occur in the vessel, causing tissue ischemia. The symptoms of Buerger's disease often are confused with PAD and other autoimmune diseases (e.g., scleroderma). Patients may have intermittent claudication of the feet, hands, or arms. As the disease progresses, rest pain and ischemic ulcerations develop. Other signs and symptoms may include color and temperature changes of the limbs, paresthesia, superficial vein thrombosis, and cold sensitivity.

There are no laboratory or diagnostic tests specific to Buerger's disease. Diagnosis is made based on age of onset; history; clinical symptoms; involvement of distal vessels; presence of ischemic ulcerations; and exclusion of autoimmune disease, diabetes, thrombophilia (inherited tendency to clot), and other source of emboli.[28]

The mainstay of treatment for Buerger's disease is the complete cessation of tobacco and marijuana use in any form. Use of nicotine replacement products is contraindicated. Patients must choose between their tobacco or marijuana and their affected limb, but not both. Conservative management includes avoiding limb exposure to cold temperatures, a supervised walking program, antibiotics to treat any infected ulcers, and analgesics to manage the ischemic pain. Teach patients to avoid trauma to the extremities.

A variety of drugs have been tried to treat Buerger's disease (e.g., calcium channel blockers, cilostazol, sildenafil [Viagra]), but evidence supporting their use is lacking. One promising drug has been IV iloprost. This has been shown to improve rest pain, promote healing of ischemic ulcers, and decrease the need for amputation.[28]

Surgical options include *sympathectomy* (transection of a nerve, ganglion, and/or plexus of the sympathetic nervous system), implantation of a spinal cord stimulator, and bypass surgery. Sympathectomy and implantation of a spinal cord stimulator can improve distal blood flow and reduce pain, but neither alters the inflammatory process. Bypass surgery typically is not an option because of the involvement of smaller, distal vessels but may be used in selected patients with severe ischemia. Painful ulcerations may require finger or toe amputations. Amputation below the knee may occur in severe cases. The rate of amputation in patients who continue tobacco or marijuana use after diagnosis is much higher than in those who stop.[28,29]

RAYNAUD'S PHENOMENON

Raynaud's phenomenon is an episodic vasospastic disorder of small cutaneous arteries, most often involving the fingers and toes. It occurs primarily in young women (typically between 15 and 40 years of age), and it is more common in women than men. The pathogenesis of Raynaud's phenomenon is due to abnormalities in the vascular, intravascular, and neuronal mechanisms that cause an imbalance between vasodilation and vasoconstriction.[30]

Raynaud's phenomenon may occur in isolation or in association with an underlying disease (e.g., rheumatoid arthritis, scleroderma, systemic lupus erythematosus). Other contributing factors include occupation-related conditions, such as use of vibrating machinery or work in cold environments, exposure to heavy metals (e.g., lead), and hyperhomocysteinemia.[30] Diagnosis is based on persistent symptoms for at least 2 years. Patients with Raynaud's phenomenon should have routine follow-up to monitor for development of connective tissue or autoimmune diseases.[31]

Raynaud's phenomenon is characterized by vasospasm-induced color changes of fingers, toes, ears, and nose (white, blue, and red). Decreased perfusion results in pallor (white). The digits then appear cyanotic (bluish purple) (Fig. 38-3). These changes are followed by rubor (red), caused by the hyperemic response that occurs when blood flow is restored. The patient usually describes coldness and numbness in the vasoconstrictive phase. This is followed by throbbing, aching pain,

FIG. 38-3 Raynaud's phenomenon.

tingling, and swelling in the hyperemic phase. An episode usually lasts only minutes but in severe cases may persist for several hours. Exposure to cold, emotional upsets, tobacco use, and caffeine often bring on symptoms.

After frequent, prolonged attacks the skin may become thickened and the nails brittle. Occasionally, complications include *punctate* (small hole) lesions of the fingertips and superficial gangrenous ulcers in advanced stages.

The primary focus of nursing management of Raynaud's phenomenon is patient teaching. Focus your instructions on preventing recurrent episodes. Tell patients to wear loose, warm clothing as protection from the cold, including gloves when handling cold objects. At all times, patients should avoid temperature extremes. Immersing hands in warm water often decreases the vasospasm. The patient should stop using all tobacco products and avoid caffeine and other drugs that have vasoconstrictive effects (e.g., cocaine, amphetamines, ergotamine, pseudoephedrine). Finally, provide patients with stress management strategies as appropriate.

When conservative management is ineffective, drug therapy is considered. Sustained-release calcium channel blockers (e.g., nifedipine [Procardia]) are the first-line drug therapy.[31] Calcium channel blockers relax smooth muscles of the arterioles by blocking the influx of calcium into the cells. This reduces the frequency and severity of vasospastic attacks.

Prompt intervention is needed for patients with digital ulceration and/or critical ischemia. Treatment options include IV prostanoid therapy (e.g., iloprost), antibiotics, analgesics, and possibly an endothelin receptor antagonist (e.g., bosentan [Tracleer]) and surgical debridement of necrotic tissue.[31] Sympathectomy is considered only in advanced cases.

AORTIC ANEURYSMS

The aorta is the largest artery and supplies oxygen, nutrients, and blood to all vital organs. One of the most common problems affecting the aorta is an **aneurysm,** which is a permanent, localized outpouching or dilation of the vessel wall. Aneurysms occur in men more often than in women, and the incidence increases with age. Aneurysms may occur in more than one location. Peripheral artery aneurysms can also develop but are not common.

Etiology and Pathophysiology

Aortic aneurysms may involve the aortic arch and thoracic and/or abdominal aorta. Three fourths of aortic aneurysms occur in the abdominal aorta (Fig. 38-4) and one fourth in the thoracic aorta. About 1.1 million adults between 55 and 84 years of age have an abdominal aortic aneurysm (AAA).[32] Most AAAs occur below the renal arteries. An abdominal aorta larger than 3 cm in diameter is considered aneurysmal. Growth rates are unpredictable, but the larger the aneurysm, the greater the risk of rupture.

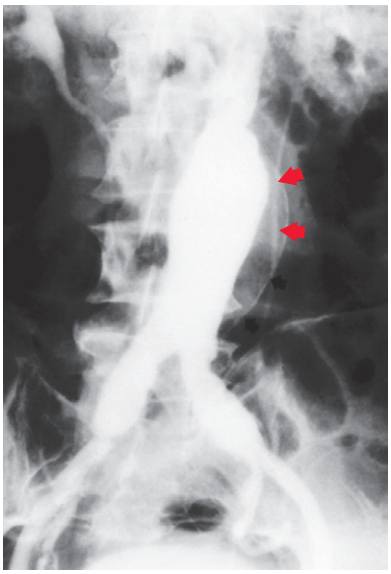

FIG. 38-4 Angiography demonstrating fusiform abdominal aortic aneurysm. Note calcification of the aortic wall *(arrows)* and extension of the aneurysm into the common iliac arteries.

A variety of disorders are associated with aortic aneurysms. The primary causes are classified as degenerative, congenital, mechanical (e.g., penetrating or blunt trauma), inflammatory (e.g., aortitis [Takayasu's arteritis]), or infectious (e.g., aortitis [*Chlamydia pneumoniae,* human immunodeficiency virus]).

Risk factors for aortic aneurysms include age, male gender, hypertension, coronary artery disease, family history, high cholesterol, lower extremity PAD, carotid artery disease, previous stroke, tobacco use, and excess weight or obesity. Male gender, older age, and tobacco use are the most important risk factors. Whites and Native Americans have a higher risk of AAA development than African Americans, Hispanics, and Asian Americans.[32]

Genetic Link

The development of aortic aneurysm and dissection has a strong genetic component. The familial tendency is related to a number of congenital anomalies. Examples include bicuspid aortic valve, coarctation of the aorta, Turner syndrome, autosomal dominant polycystic kidney disease, specific collagen defects (e.g., Ehlers-Danlos syndrome), and premature breakdown of vascular elastic tissue (e.g., Loeys-Dietz syndrome, Marfan's syndrome).[33]

Classification

Aneurysms are classified as true or false aneurysms (Fig. 38-5, *A* to *C*). A *true aneurysm* is one in which the wall of the artery forms the aneurysm, with at least one vessel layer still intact. True aneurysms are further subdivided into fusiform and saccular types. A *fusiform aneurysm* is circumferential and relatively uniform in shape. A *saccular aneurysm* is pouchlike with

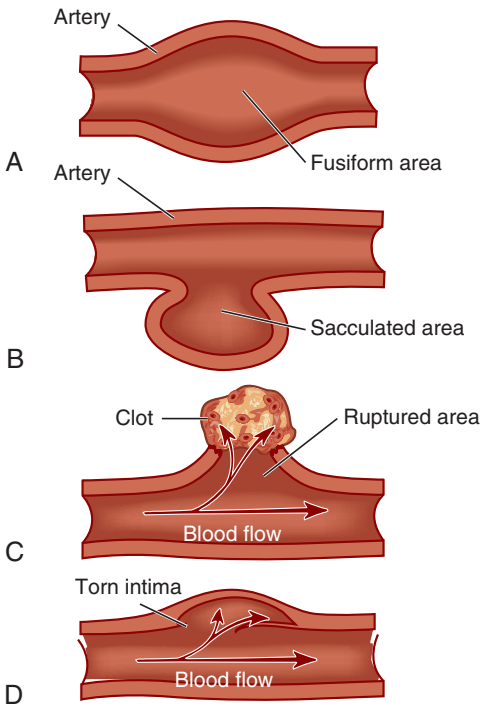

FIG. 38-5 **A,** True fusiform abdominal aortic aneurysm. **B,** True saccular aortic aneurysm. **C,** False aneurysm, or pseudoaneurysm. **D,** Aortic dissection.

a narrow neck connecting the bulge to one side of the arterial wall.

A *false aneurysm,* or *pseudoaneurysm,* is not an aneurysm but a disruption of all arterial wall layers with bleeding that is contained by surrounding anatomic structures. False aneurysms may result from trauma, infection, peripheral artery bypass graft surgery (at the site of the graft-to-artery anastomosis), or arterial leakage after removal of cannulae (e.g., femoral artery catheters, intraaortic balloon pump devices).[33]

Clinical Manifestations

Thoracic aortic aneurysms (TAAs) are often asymptomatic. When present, symptoms include deep, diffuse chest pain that may extend to the interscapular area. Ascending aorta and aortic arch aneurysms can produce angina from decreased blood flow to the coronary arteries and hoarseness from pressure on the laryngeal nerve. Pressure on the esophagus can cause dysphagia. If the aneurysm presses on the superior vena cava, decreased venous return can result in jugular venous distention (distended neck veins) and edema of the face and the arms.

AAAs also are often asymptomatic and frequently found during routine physical examinations or evaluations for an unrelated problem (e.g., abdominal x-ray, computed tomography [CT] scan). A pulsatile mass in the periumbilical area slightly to the left of the midline may be present. Bruits may be auscultated over the aneurysm. Physical findings may be more difficult to detect in obese individuals.

AAA symptoms may mimic pain associated with abdominal or back disorders. Compression of nearby anatomic structures and nerves may cause symptoms such as back pain, epigastric discomfort, and altered bowel elimination. Occasionally, aneurysms spontaneously embolize plaque, causing *"blue toe syndrome"* (patchy mottling of the feet and toes in the presence of palpable pedal pulses).

Complications

Rupture of an aneurysm is the most serious complication. If rupture occurs into the retroperitoneal space, bleeding may be controlled by surrounding anatomic structures, preventing exsanguination and death. In this case the patient often has severe back pain and may or may not have back or flank ecchymosis *(Grey Turner's sign)*. If rupture occurs into the thoracic or abdominal cavity, more than 90% of patients will die from massive hemorrhage.[4] The patient who reaches the hospital will be in hypovolemic shock with tachycardia, hypotension, pale clammy skin, decreased urine output, altered level of consciousness, and abdominal tenderness. (Shock is discussed in Chapter 67.) In this situation, simultaneous resuscitation and immediate surgical repair are necessary.

Diagnostic Studies

Chest x-rays are done to reveal abnormal widening of the thoracic aorta. An abdominal x-ray may show calcification within the aortic wall. An electrocardiogram (ECG) may rule out MI, since thoracic aneurysm or dissection symptoms can mimic angina. Echocardiography assesses the function of the aortic valve. Ultrasound is useful for aneurysm screening and to monitor aneurysm size. A CT scan is the most accurate test to determine the length and cross-sectional diameter and the presence of thrombus in the aneurysm. Magnetic resonance imaging (MRI) also may be used to diagnose and assess the location and severity of aneurysms. *Angiography* provides helpful information by using contrast imaging to map the entire aortic system. (Chapter 32 and Table 32-6 discuss angiography.)

Collaborative Care

The goal of both medical and surgical management is to prevent aneurysm rupture. Early detection and prompt treatment are essential. Conservative therapy of small, asymptomatic AAAs (4.0 to 5.5 cm) is the best practice.[34] This consists of risk factor modification (ceasing tobacco use, decreasing BP, optimizing lipid profile) and annual monitoring of aneurysm size using ultrasound, CT, or MRI. Growth rates may be lowered with β-adrenergic blocking agents (e.g. propranolol [Inderal]), statins (e.g., simvastatin), and antibiotics (e.g., doxycycline).[33]

Surgical repair is recommended in patients with asymptomatic aneurysms 5.5 cm in diameter or larger. Surgical intervention may occur sooner if the patient has a genetic disorder (e.g., Marfan's, Ehlers-Danlos syndrome), the aneurysm expands rapidly, it becomes symptomatic, or the risk of rupture is high.[12] A careful review of body systems is necessary to identify any co-morbidities, especially of the lungs, heart, or kidney, because they can influence the patient's surgical risk. Correction of existing carotid or coronary artery blockages may be needed before the aneurysm is repaired.

Surgical Therapy. For elective surgery, the patient is well hydrated, and any electrolyte, coagulation, and hematocrit abnormalities are corrected preoperatively. If the aneurysm has ruptured, emergent surgical intervention is required.

The open aneurysm repair (OAR) involves a large abdominal incision through which the surgeon (1) cuts into the diseased aortic segment, (2) removes any thrombus or plaque, (3) sutures a synthetic graft to the aorta proximal and distal to the aneurysm, and (4) sutures the native aortic wall around the graft to

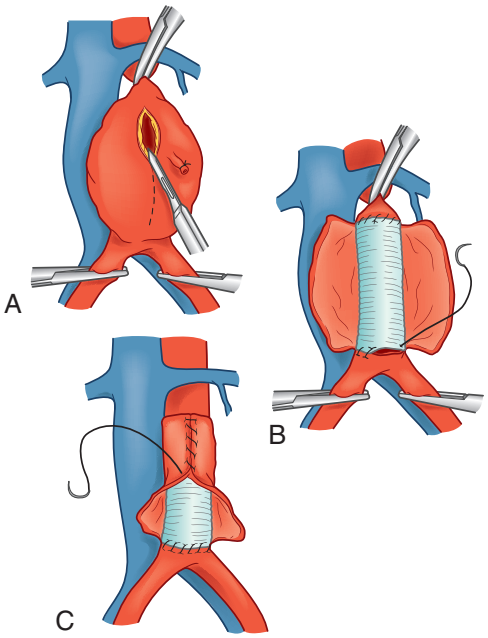

FIG. 38-6 Surgical repair of an abdominal aortic aneurysm. **A,** Incising the aneurysmal sac. **B,** Insertion of synthetic graft. **C,** Suturing native aortic wall over synthetic graft.

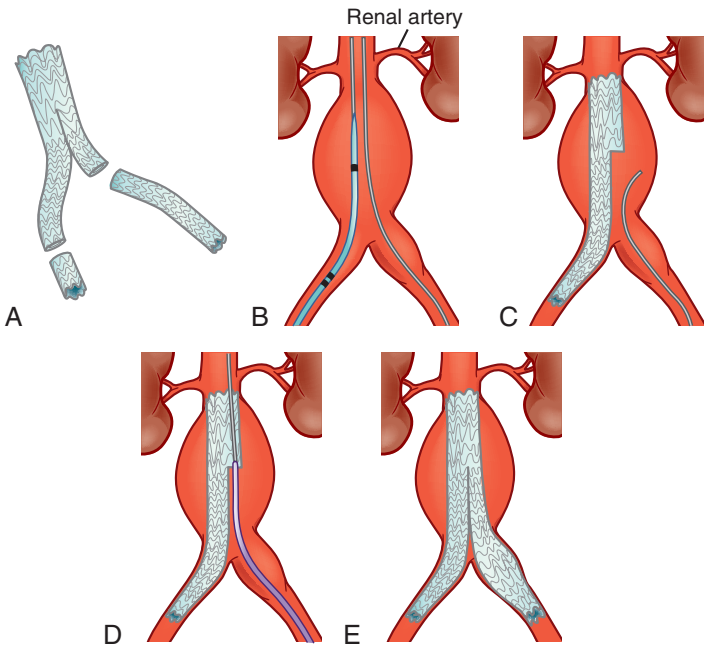

FIG. 38-7 Bifurcated (two-branched) endovascular stent grafting of an aneurysm. **A,** Insertion of a woven polyester tube (graft) covered by a tubular metal web (stent). **B,** The stent graft is inserted through a large blood vessel (e.g., femoral artery) using a delivery catheter. The catheter is positioned below the renal arteries in the area of the aneurysm. **C,** The stent graft is slowly released (deployed) into the blood vessel. When the stent comes in contact with the blood vessel, it expands to a preset size. **D,** A second stent graft can be inserted in the contralateral (opposite) vessel if necessary. **E,** Fully deployed bifurcated stent graft.

act as a protective cover (Fig. 38-6). If the iliac arteries are also aneurysmal, a bifurcated graft replaces the entire diseased segment. With saccular aneurysms, it may be possible to excise only the bulbous lesion, repairing the artery by primary closure (suturing the artery together) or by application of an autogenous or synthetic patch graft.

All OARs require aortic cross-clamping proximal and distal to the aneurysm. Most resections are done in 30 to 45 minutes, after which the clamps are removed and blood flow is restored. If the cross clamp must be applied above the renal arteries, adequate renal blood flow after clamp removal should be determined before closure of the abdominal incision. The risk of postoperative renal complications such as acute kidney injury increases in patients who have OAR of AAAs above the level of the renal arteries.

Endovascular Graft Procedure. Minimally invasive endovascular aneurysm repair (EVAR) is an alternative to conventional OAR. Patients must meet certain eligibility criteria to be candidates for EVAR. These include iliofemoral vessels that will allow for safe graft insertion and vessels of sufficient length and width to support the graft.[33]

EVAR involves the placement of a sutureless aortic graft into the abdominal aorta inside the aneurysm via the femoral artery. The graft, a Dacron cylinder consisting of several sections, is supported with multiple rings of flexible wire (Fig. 38-7). The main section of the graft is bifurcated and delivered through a femoral artery catheter. The second part of the graft is inserted through the opposite femoral artery. When all graft components are in place, they are released (deployed) against the vessel wall by balloon inflation. The blood then flows through the endovascular graft, thus preventing further expansion of the aneurysm. The aneurysmal wall will shrink over time because the blood is now being diverted through the endograft.

Complications. EVAR is less invasive than OAR. However, over time both techniques have similar rates of morbidity and mortality.[12,35]

The most common complication of AAA repair is *endoleak,* the seepage of blood back into the old aneurysm. This may be the result of an inadequate seal at either graft end, a tear through the graft fabric, or leakage between overlapping graft segments. Repair may require coil embolization (insertion of beads) for hemostasis.

Other potential complications include aneurysm growth above or below the graft, aneurysm rupture, aortic dissection, bleeding, renal artery occlusion caused by stent migration, graft thrombosis, incisional site hematoma, and incisional infection. Patients undergoing EVAR must have regular follow-up visits and routine CT or MRI scans for the rest of their lives to monitor for complications. Graft dysfunction may require conversion to an open surgical repair.

A potentially lethal complication in an emergency repair of a ruptured AAA is the development of *intraabdominal hypertension* (IAH) with associated *abdominal compartment syndrome* (ACS).[36] Persistent IAH reduces blood flow to the viscera. ACS refers to the impaired end-organ perfusion caused by IAH and resulting multisystem organ failure.

ACS occurs in about one fourth of cases of ruptured OARs and EVARs. It has a mortality rate up to 70%.[37] IAH is confirmed by measuring the patient's intraabdominal pressure indirectly through a catheter and transducer system, typically by using an indwelling urinary catheter. Treatment goals include control of situations that lead to IAH such as head of bed elevation, hemodynamic instability, and uncontrolled pain and anxiety. A percutaneous catheter decompression may be required in the patient with severe ACS to reduce intraabdominal pressure.[38]

NURSING MANAGEMENT
AORTIC ANEURYSMS

NURSING ASSESSMENT

Begin by performing a thorough history and physical assessment. Because atherosclerosis is a systemic disease, look for signs of coexisting cardiac, pulmonary, cerebral, and lower extremity vascular problems. Monitor the patient for signs of aneurysm rupture, such as diaphoresis; pallor; weakness; tachycardia; hypotension; abdominal, back, groin, or periumbilical pain; changes in level of consciousness; or a pulsating abdominal mass.

Establishing baseline data is critical for comparison with later postoperative assessments. Pay special attention to the character and quality of the patient's peripheral pulses, and renal and neurologic status. Before surgery, mark pedal pulse sites (dorsalis pedis and posterior tibial) with a single-use marker and document any skin lesions on the lower extremities.

PLANNING

The overall goals for a patient undergoing aortic surgery include (1) normal tissue perfusion; (2) intact motor and sensory function; and (3) no complications related to surgical repair, such as thrombosis, infection, or rupture.

NURSING IMPLEMENTATION

HEALTH PROMOTION. To promote overall health, encourage the patient to reduce CVD risk factors (see Table 34-2), including controlling BP, ceasing tobacco use (see Chapter 11), increasing physical activity, and maintaining normal body weight and serum lipid levels. These measures also help ensure continued graft patency after surgical repair.

ACUTE INTERVENTION. During the preoperative period, provide emotional support and teaching to the patient and the caregiver. Preoperative teaching includes a brief explanation of the disease process, the planned surgical procedure(s), preoperative routines, what to expect immediately after surgery (e.g., recovery room, tubes and drains), and usual postoperative timelines. Specific preoperative routines vary by agency and surgeon. In general, aortic surgery patients have a bowel preparation (e.g., laxatives, enemas) and skin cleansing with an antimicrobial agent the day before surgery, have nothing by mouth (NPO) after midnight the day of surgery, and receive IV antibiotics immediately before the incision is made. If appropriate, a preoperative visit to the intensive care unit (ICU) may be helpful to the patient and caregiver. Patients with a history of CVD should receive a β-adrenergic blocker (e.g., metoprolol [Lopressor]) preoperatively to reduce morbidity and mortality.

Postoperatively, aortic surgery patients typically go to an ICU for 24 to 48 hours for close monitoring. When the patient arrives in the ICU, various devices are in place. These include an endotracheal tube for mechanical ventilation, an arterial line, a central venous pressure (CVP) or pulmonary artery (PA) catheter, peripheral IV lines, an indwelling urinary catheter, and a nasogastric (NG) tube. The patient needs continuous ECG and pulse oximetry monitoring. If the thorax is opened during surgery, chest tubes will be in place. Pain medication is given via epidural catheter or patient-controlled analgesia (PCA).

In addition to the usual goals of care for a postoperative patient (e.g., maintaining adequate respiratory function, fluid and electrolyte balance, and pain control [see Chapter 20]), check for graft patency and renal perfusion. Also watch for and intervene to limit or treat cardiac ischemia, dysrhythmias, infections, VTE, and neurologic complications. eNursing Care Plan 38-2 for the patient with an aneurysm repair or other aortic surgery is available on the website for this chapter.

Graft Patency. An adequate BP is important to maintain graft patency. Prolonged low BP may result in graft thrombosis. Administer IV fluids and blood components as ordered to maintain adequate blood flow. Monitor CVP or PA pressures and urine output hourly in the immediate postoperative period to assess the patient's hydration and perfusion status.

Avoid severe hypertension, since it may cause undue stress on the arterial anastomoses, resulting in leakage of blood or rupture at the suture lines. Drug therapy with IV diuretics (e.g., furosemide [Lasix]) or IV antihypertensive agents (e.g., labetalol [Normodyne], metoprolol, hydralazine [Apresoline], sodium nitroprusside [Nipride]) may be indicated.

Cardiovascular Status. Myocardial ischemia or infarction may occur in the perioperative period because of decreased myocardial oxygen supply or increased myocardial oxygen demands. Cardiac dysrhythmias may occur because of electrolyte imbalances, hypoxemia, hypothermia, or myocardial ischemia. Nursing interventions include continuous ECG monitoring; frequent electrolyte and arterial blood gas determinations; administration of oxygen, IV antidysrhythmic and antihypertensive medications, and electrolytes as needed; adequate pain control; and resumption of heart medications.

Infection. A prosthetic vascular graft infection is a relatively rare but potentially life-threatening complication. Nursing interventions to prevent infection include administering a broad-spectrum antibiotic as prescribed. Assess temperature regularly, and promptly report elevations. Monitor laboratory data for an elevated white blood cell (WBC) count, which may be the first indication of an infection. Ensure adequate nutrition, and assess the surgical incision for signs of infection (e.g., redness, swelling, drainage). Keep surgical incisions clean and dry and perform wound care as ordered.

Use strict aseptic technique in the care of all IV, arterial, and CVP or PA catheter insertion sites, since these are ports of entry for bacteria. Meticulous perineal care for the patient with an indwelling urinary catheter and early catheter removal are essential to minimize the risk of urinary tract infection.

Gastrointestinal Status. After OAR, postoperative ileus may develop as a result of anesthesia and the handling of the bowel during surgery. The intestines may become swollen and bruised, and peristalsis ceases for variable intervals. A retroperitoneal surgical approach can be used to decrease the risk of bowel complications.

An NG tube may be placed during surgery and connected to low, intermittent suction to decompress the stomach, prevent aspiration of stomach contents, and decrease pressure on suture lines. Record the amount and character of the NG output. While the patient is NPO, provide oral care frequently. Ice chips or lozenges can help soothe a dry or irritated throat. Assess for bowel sounds every 4 hours. The passing of flatus signals returning bowel function and should be noted. Encourage early ambulation, since this can help the return of bowel function. A postoperative ileus rarely lasts beyond the fourth postoperative day.

If the blood supply to the bowel is disrupted during surgery, temporary ischemia or infarction (death) of intestinal tissue may result. Clinical manifestations of this rare but serious complication include absent bowel sounds, fever, abdominal disten-

tion and pain, diarrhea, and bloody stools. If bowel infarction occurs, immediate reoperation is necessary to restore blood flow, with likely resection of the infarcted bowel.

Neurologic Status. Neurologic complications can occur after aortic surgery. When the ascending aorta and aortic arch are involved, assess the patient's level of consciousness, pupil size and response to light, facial symmetry, tongue position, speech, upper extremity movement, and quality of hand grasps (see Chapter 57). When the descending aorta is involved, perform a neurovascular assessment of the lower extremities. Record all assessments and report changes from baseline to the physician immediately.

Peripheral Perfusion Status. The location of the aneurysm determines what type of peripheral perfusion assessment is done. Check and record all peripheral pulses hourly for several hours and then routinely, based on agency policy. When the ascending aorta and aortic arch are involved, assess the carotid, radial, and temporal artery pulses. For surgery of the descending aorta, assess the femoral, popliteal, posterior tibial, and dorsalis pedis pulses (see Fig. 32-6). You may need a Doppler to assess peripheral pulses. Check skin temperature and color, capillary refill time, and sensation and movement of the extremities (see Chapter 32).

Occasionally, lower extremity pulses may be absent for a short time after surgery because of vasospasm and hypothermia. A decreased or absent pulse together with a cool, pale, mottled, or painful extremity may indicate embolization or graft occlusion. Report these findings to the physician immediately. Graft occlusion requires reoperation if identified early. Thrombolytic therapy may also be considered. In some patients, pulses may have been absent before surgery because of coexistent PAD. It is essential to compare your findings with the preoperative status to determine the cause of a decreased or absent pulse and the proper treatment.

Renal Perfusion Status. The patient will have an indwelling urinary catheter after surgery. In the immediate postoperative period, record hourly urine output. Further evaluate renal function by monitoring daily blood urea nitrogen (BUN) and serum creatinine levels. CVP and PA pressures also provide important information about hydration status. Maintain accurate fluid intake and output and record daily weights until the patient resumes a regular diet.

Decreased renal perfusion can occur from embolization of the aortic thrombus or plaque to one or both of the renal arteries. This causes ischemia of one or both kidneys. Hypotension, dehydration, prolonged aortic clamping during surgery, or blood loss also can lead to decreased renal perfusion. Irreversible renal failure may occur after surgery, particularly in high-risk people (e.g., patients with diabetes). (Acute kidney injury is discussed in Chapter 47.)

AMBULATORY AND HOME CARE Instruct the patient and caregiver to gradually increase activities once home. Fatigue, poor appetite, and irregular bowel habits are common. Teach the patient to avoid heavy lifting for 6 weeks after surgery. Any redness, swelling, increased pain, drainage from incisions, or fever greater than 100° F (37.8° C) should be reported to a health care provider.

Teach the patient and caregiver to look for changes in color or warmth of the extremities. Patients and caregivers can learn to palpate peripheral pulses to assess changes in their quality.

Sexual dysfunction in male patients is common after aortic surgery. Preoperatively, document baseline sexual function and recommend counseling as appropriate. A referral to a urologist may be useful if erectile dysfunction occurs.

EVALUATION

Expected outcomes for the patient who undergoes aortic surgery include the following:

- Patent arterial graft with adequate distal perfusion
- Adequate urine output
- No signs of infection

AORTIC DISSECTION

Aortic dissection, often misnamed *"dissecting aneurysm,"* is not a type of aneurysm. Rather, dissection results from the creation of a false lumen between the intima (inner lining) and the media (middle layer) of arterial wall (Figs. 38-5, *D,* and 38-8). Classification of the aortic dissection is based on anatomic location (ascending versus descending aorta) and duration of onset (acute versus chronic). Approximately two thirds of dissections involve the ascending aorta and are acute in onset.[39] Chronic dissections almost always involve the descending aorta.

Etiology and Pathophysiology

Most experts link nontraumatic aortic dissection to degenerated elastic fibers in the arterial wall. Chronic hypertension hastens this process. In aortic dissection a tear develops in the inner layer of the aorta. Blood surges through this tear into the middle layer of the aorta, causing the inner and middle layers to separate (dissect). If the blood-filled channel ruptures through the outside aortic wall, aortic dissection is often fatal.

As the heart contracts, each pulsation increases the pressure on the damaged area, which further increases the dissection. Extension of the dissection may cut off blood supply to critical areas such as the brain, kidneys, spinal cord, and extremities. The false lumen may remain patent, become thrombosed (clotted), rejoin the true lumen by way of a distal tear, or rupture.

Aortic dissection affects men 2 to 5 times more often than women and occurs most frequently in the sixth and seventh decades of life.[39] Predisposing factors include age, aortitis (e.g., syphilis), blunt or iatrogenic trauma, congenital heart disease (e.g., bicuspid aortic valve), connective tissue disorders (e.g., Marfan's syndrome), cocaine or methamphetamine use, history of heart surgery, atherosclerosis, male gender, pregnancy, and hypertension.[33] Younger patients are more likely to have a bicus-

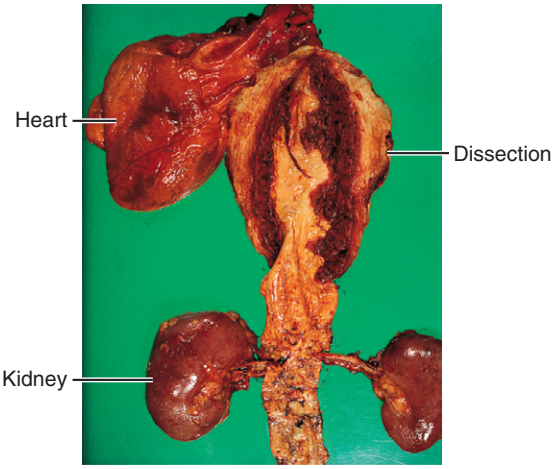

FIG. 38-8 Aortic dissection of the thoracic aorta.

pid aortic valve, Marfan's syndrome, prior aortic valve surgery, or recent trauma. Nearly half of all dissections in women younger than 40 years occur during pregnancy.

Clinical Manifestations

Most patients with an acute ascending aortic dissection report abrupt onset of excruciating chest and/or back pain radiating to the neck or shoulders. Patients with acute descending aortic dissection are more likely to report pain located in their back, abdomen, or legs. The pain is frequently described as "sharp" and "worst ever," or as "tearing," "ripping," or "stabbing."

Dissection pain can be differentiated from MI pain, which is more gradual in onset and has increasing intensity. As the dissection progresses, pain may migrate. Older patients are less likely to have abrupt onset of chest or back pain and more likely to have hypotension and vague symptoms. Some patients have a painless aortic dissection, emphasizing the importance of the physical examination.

If the aortic arch is involved, the patient may exhibit neurologic deficits. These include altered level of consciousness, weakened or absent carotid and temporal pulses, and dizziness or syncope. An ascending aortic dissection usually produces some degree of disruption in blood flow in the coronary arteries and aortic valve insufficiency. The patient may develop angina; MI; and a new high-pitched, heart murmur. In severe cases, these complications can result in left heart failure with the development of dyspnea, orthopnea, and pulmonary edema. When either subclavian artery is involved, radial, ulnar, and brachial pulse quality and BP readings may be different between the left and right arms. As the dissection progresses down the aorta, the abdominal organs and the lower extremities demonstrate evidence of decreased tissue perfusion.

Complications

A severe and life-threatening complication of an acute ascending aortic dissection is *cardiac tamponade*. This occurs when blood from the dissection leaks into the pericardial sac. Clinical manifestations of tamponade include hypotension, narrowed pulse pressure, jugular venous distention, muffled heart sounds, and pulsus paradoxus (see Chapter 37).

The aorta may rupture because it is weakened by the dissection. Hemorrhage may occur into the mediastinal, pleural, or abdominal cavities. Aortic rupture typically results in exsanguination and death. Dissection can lead to occlusion of the blood supply to vital organs. Spinal cord ischemia leads to weakness and decreased sensation to complete lower extremity paralysis. Renal ischemia can lead to renal failure. Abdominal (mesenteric) ischemia can cause abdominal pain, decreased bowel sounds, altered bowel function, and bowel necrosis.

Diagnostic Studies

Diagnostic studies to detect aortic dissection are similar to those for suspected aneurysms (Table 38-6). An ECG can help rule out cardiac ischemia. A chest x-ray may show a widening of the mediastinum and pleural effusion. Three-dimensional (3-D) CT scanning and transesophageal echocardiography (TEE) have become the standard for the diagnosis of acute aortic dissection. A CT scan can provide valuable information on the presence and severity of the dissection. Although an MRI has the highest accuracy for detecting aortic dissection, it is contraindicated in some patients (e.g., those with metal implants, hemodynamically unstable patients).[39]

TABLE 38-6 COLLABORATIVE CARE

Aortic Dissection

Diagnostic	Collaborative Therapy
• Health history and physical examination • ECG • Chest x-ray • CT scan with 3-D reconstruction • Transesophageal echocardiogram • Magnetic resonance imaging	• Bed rest • Pain relief with opioids • Blood transfusion (if necessary) • Drug therapy (see Table 33-7) • IV β-adrenergic blockers (e.g., esmolol [Brevibloc], propranolol [Inderal]) • IV calcium channel blockers • Angiotensin-converting enzyme inhibitors • Sodium nitroprusside (Nipride) • Surgical aortic resection and repair • Endovascular aortic dissection repair

Collaborative Care

Patients with acute aortic dissection are managed in the ICU. The initial goals of therapy for acute aortic dissection without complications are heart rate (HR) and BP control and pain management. HR and BP control reduces aortic wall stress by decreasing systolic BP and myocardial contractility (see Table 38-6). An IV β-adrenergic blocker (e.g., esmolol [Brevibloc]) is titrated to a target HR of 60 beats/minute or less. A calcium channel blocker (e.g., diltiazem [Cardizem], verapamil [Calan]) can be used to lower HR if a β-adrenergic blocker is contraindicated. An IV ACE inhibitor (e.g., enalapril [Vasotec]) may also be used. Reducing the HR, BP, and myocardial contractility limits extension of the dissection. Morphine is the preferred analgesic because it decreases sympathetic nervous system stimulation and relieves pain. Supportive treatment for an acute aortic dissection serves as a bridge to surgery.

Conservative Therapy. The patient with an acute or chronic descending aortic dissection without complications can be treated conservatively. Conservative treatment includes pain relief, HR and BP control, and CVD risk factor modification.

Endovascular Dissection Repair. Endovascular repair of acute descending aortic dissections with complications (e.g., hemodynamic instability) and chronic descending aortic dissection with complications (e.g., peripheral ischemia) is a treatment option. Endovascular dissection repair is similar to EVAR. However, a temporary lumbar drain may be inserted for cerebrospinal fluid removal to reduce spinal cord edema and help prevent paralysis.[40]

Surgical Therapy. An acute ascending aortic dissection is considered a surgical emergency. Otherwise, surgery is indicated when conservative therapy is ineffective or when complications (e.g., heart failure) occur. Open surgical repair is recommended for patients with a chronic dissection who have a connective tissue disorder and a descending thoracic aortic diameter greater than 5.5 cm.[33] The aorta is fragile after dissection. Thus surgery is delayed for as long as possible to allow time for edema to decrease and to permit clotting of the blood in the false lumen. Surgery involves resection of the aortic segment containing the intimal tear and replacement with a synthetic graft. Even with prompt surgical intervention, the in-hospital mortality rate of acute aortic dissection is high.[39] Causes of death include aortic rupture, mesenteric ischemia, MI, sepsis, and multiorgan failure.

NURSING MANAGEMENT AORTIC DISSECTION

Preoperatively, nursing management includes keeping the patient in bed in a semi-Fowler's position and maintaining a quiet environment. These measures help to keep the HR and the systolic BP at the lowest possible level that maintains vital organ perfusion (typically HR less than 60 beats/minute; systolic BP less than 120 mm Hg). Administer opioids and sedatives as ordered. To prevent extension of the dissection, manage pain and anxiety because they can cause elevations in the HR and systolic BP.

Administration and titration of IV antihypertensive agents require careful supervision, including continuous ECG and intraarterial BP monitoring (see Chapters 36 and 66). Monitor vital signs frequently, sometimes as often as every 2 to 3 minutes, until target HR and BP are reached. Observe for changes in peripheral pulses and signs of increasing pain, restlessness, and anxiety. If the arteries branching off the aortic arch are involved, decreased cerebral blood flow may alter the patient's level of consciousness. Postoperative care is similar to that after OAR (see earlier section on nursing management of aortic aneurysms).

In preparation for discharge, focus on patient and caregiver teaching. All patients with a history of aortic dissection, regardless of location or treatment approach, require long-term medical care to control HR and BP. Patients must understand that they need to take antihypertensive drugs daily for the rest of their lives. β-Adrenergic blockers (e.g., metoprolol) are used to control HR and BP and decrease myocardial contractility. It is important that patients understand the drug regimen and potential side effects (e.g., dizziness, depression, fatigue, erectile dysfunction). Tell the patient to discuss any side effects with the health care provider before discontinuing the drug. Follow-up with regularly scheduled MRIs or CTs is essential. The most common cause of death in long-term survivors is aortic rupture from redissection or aneurysm formation. Instruct patients that if the pain or other symptoms return, they should activate emergency medical services (EMS) for immediate care.

VENOUS DISORDERS

PHLEBITIS

Generally, every hospitalized patient has an IV catheter inserted for giving fluids and/or drugs. *Phlebitis* is inflammation of the walls of small cannulated veins of the hand or arm. Clinical signs and symptoms include pain, tenderness, warmth, erythema, swelling, and a palpable cord.[41] Phlebitis risk factors are mechanical irritation from the catheter, infusion of irritating medications, and catheter location. Phlebitis is rarely infectious and usually resolves quickly after catheter removal. If edema is present, elevate the extremity to promote reabsorption of fluid into the vasculature. Apply warm, moist heat and administer oral NSAIDs (e.g., diclofenac [Voltaren]) or topical NSAIDs (e.g., diclofenac gel [Solaraze]) to relieve pain and inflammation.

VENOUS THROMBOSIS

Venous thrombosis involves the formation of a thrombus in association with inflammation of the vein. It is the most common disorder of the veins and is classified as either superficial vein thrombosis or deep vein thrombosis. **Superficial vein thrombosis (SVT)** is the formation of a thrombus in a superficial vein, usually the greater or lesser saphenous vein. **Deep vein thrombosis (DVT)** is a disorder involving a thrombus in a deep vein, most commonly the iliac and femoral veins. **Venous thromboembolism (VTE)** is the preferred terminology and represents the spectrum of pathology from DVT to pulmonary embolism (PE) (Table 38-7). (Chapter 28 discusses PE.)

SVT has been considered a benign disorder. However, recent data indicate that SVT may be more serious. Nearly 25% of patients with SVT may also have VTE at the time of diagnosis. Further, between 5% and 10% of SVT patients are at risk for developing thromboembolic complications in the future.[42]

TABLE 38-7 COMPARISON OF SUPERFICIAL VEIN THROMBOSIS AND VENOUS THROMBOEMBOLISM

	Superficial Vein Thrombosis	Venous Thromboembolism (VTE)
Usual location	Typically, superficial leg veins (e.g., varicosities). Occasionally superficial arm veins.	Deep veins of arms (e.g., axillary, subclavian), legs (e.g., femoral), pelvis (e.g., iliac, inferior or superior vena cava), and pulmonary system.
Clinical findings	Tenderness, itchiness, redness, warmth, pain, inflammation and induration along the course of the superficial vein. Vein appears as a palpable cord. Edema rarely occurs.	Tenderness to pressure over involved vein, induration of overlying muscle, venous distention. Edema. May have mild to moderate pain, deep reddish color to area caused by venous congestion. NOTE: Some patients may have no obvious physical changes in the affected extremity.
Sequelae	If untreated, clot may extend to deeper veins and VTE may occur.	Embolization to lungs (pulmonary embolism) may occur and may result in death.* Pulmonary hypertension and post-thrombotic syndrome with or without venous leg ulceration may develop.

*See Chapter 28 for clinical findings related to pulmonary embolism.

Etiology

Three important factors (called **Virchow's triad**) in the etiology of venous thrombosis are (1) venous stasis, (2) damage of the endothelium (inner lining of the vein), and (3) hypercoagulability of the blood (Fig. 38-9). The patient at risk for the development of VTE usually has predisposing conditions to these three disorders (Table 38-8).

Venous Stasis. Normal venous blood flow depends on the action of muscles in the extremities and the functional adequacy of venous valves, which allow flow in one direction. *Venous stasis* occurs when the valves are dysfunctional or the muscles of the extremities are inactive. Venous stasis occurs more frequently in people who are obese or pregnant, have chronic heart failure or atrial fibrillation, have been traveling on long trips without regular exercise, have a prolonged surgical procedure, or are immobile for long periods (e.g., spinal cord injury, fractured hip, limb paralysis).[43]

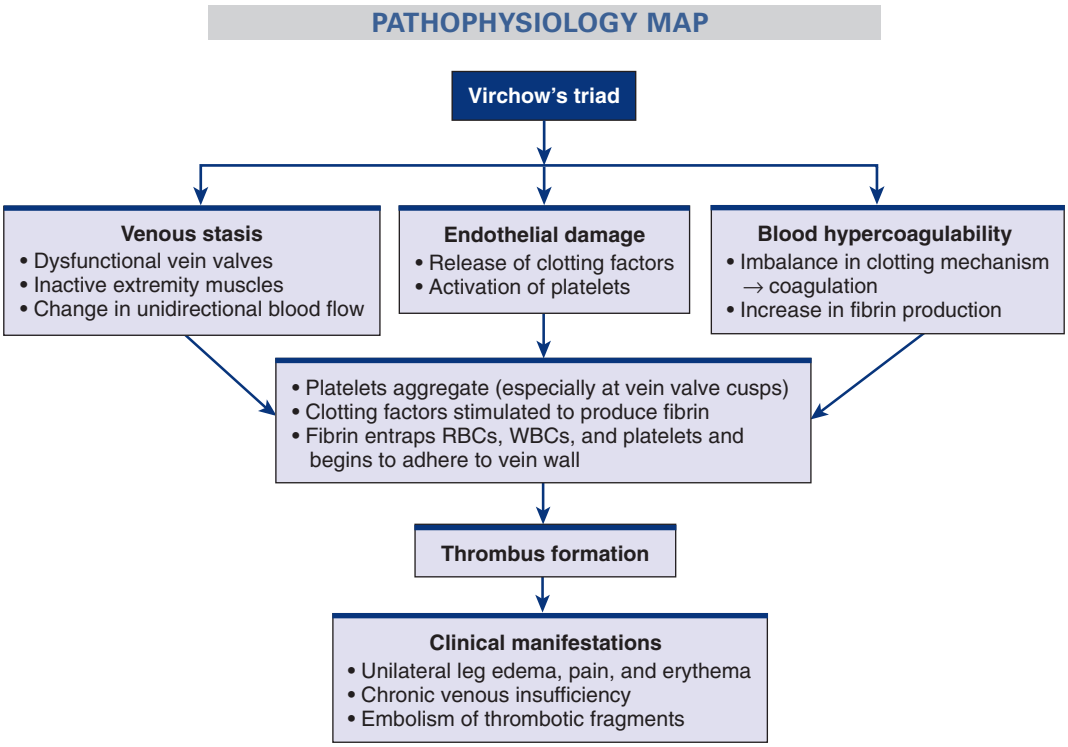

FIG. 38-9 Pathophysiology of venous thromboembolism.

TABLE 38-8 RISK FACTORS FOR VENOUS THROMBOEMBOLISM

Venous Stasis
- Advanced age
- Atrial fibrillation
- Chronic heart failure
- Obesity
- Orthopedic surgery (especially hip or lower extremity)
- Pregnancy and postpartum period
- Prolonged immobility
  - Bed rest
  - Fractured leg or hip
  - Long trips without adequate exercise
  - Spinal cord injury or limb paralysis
- Stroke
- Varicose veins

Endothelial Damage
- Abdominal and pelvic surgery (e.g., gynecologic or urologic surgery)
- Caustic or hypertonic IV medications
- Fractures of the pelvis, hip, or leg
- History of previous venous thromboembolism
- Indwelling, peripherally inserted, central vein catheter
- IV drug abuse
- Trauma

Hypercoagulability of Blood
- Antiphospholipid antibody syndrome
- Antithrombin III deficiency
- Dehydration or malnutrition
- Elevated (clotting) factor VIII or lipoprotein (a)
- Erythropoiesis-stimulating drugs (e.g., epoetin alfa [Procrit])
- Factor V Leiden or prothrombin gene mutation
- High altitudes
- Hormone therapy
- Hyperhomocysteinemia
- Malignancies (especially breast, brain, hepatic, pancreatic, and gastrointestinal)
- Nephrotic syndrome
- Oral contraceptives, especially in women >35 yr who use tobacco
- Polycythemia vera
- Pregnancy and postpartum period
- Protein C deficiency
- Protein S deficiency
- Sepsis
- Severe anemias
- Tobacco use

Endothelial Damage. Damage to the endothelium of the vein may be caused by direct (e.g., surgery, intravascular catheterization, trauma, burns) or indirect (chemotherapy, diabetes, sepsis) injury to the vessel.[43] Damaged endothelium stimulates platelet activation and starts the coagulation cascade. This predisposes the patient to thrombus development.

Hypercoagulability of Blood. Hypercoagulability of blood occurs in many disorders, including severe anemias, polycythemia, malignancies (e.g., cancers of the breast, brain, pancreas, and gastrointestinal tract), nephrotic syndrome, hyperhomocysteinemia, and protein C and S deficiency.[43] A patient with sepsis is predisposed to hypercoagulability because of endotoxins that are released. Some medications (e.g., corticosteroids, estrogens) predispose a patient to thrombus formation.

Women of childbearing age who take estrogen-based oral contraceptives or postmenopausal women on oral hormone therapy (HT) are at increased risk for VTE.[43] Women who use oral contraceptives and tobacco double their risk. Smoking causes hypercoagulability by increasing plasma fibrinogen and homocysteine levels and activating the intrinsic coagulation pathway. Women who use tobacco and oral contraceptives, are over 35 years old, and have a family history of VTE are at an extremely high risk for VTE. In women with a known thrombophilia, the benefits of HT, tamoxifen (Nolvadex), or raloxifene (Evista) must be weighed against the risk for VTE.

Pathophysiology

Localized platelet aggregation and fibrin entrap red blood cells (RBCs), WBCs, and more platelets to form a thrombus. A frequent site of thrombus formation is the valve cusps of veins, where venous stasis occurs. As the thrombus enlarges, increased numbers of blood cells and fibrin collect behind it. This produces a larger clot with a "tail" that eventually blocks the lumen of the vein.

If a thrombus only partially blocks the vein, endothelial cells cover the thrombus and stop the thrombotic process. If the thrombus does not become detached, it undergoes lysis or becomes firmly organized and adherent within 5 to 7 days. The organized thrombus may detach and result in an embolus. Turbulence of blood flow is a major contributing factor to embolization. The thrombus can become an embolus that flows through the venous circulation to the heart and lodges in the pulmonary circulation, becoming a PE (see Fig. 28-11).

Superficial Vein Thrombosis

Clinical Manifestations. The patient with SVT may have a palpable, firm, subcutaneous cordlike vein (see Table 38-7). The area surrounding the vein may be itchy, tender or painful to the touch, reddened, and warm. A mild temperature elevation and leukocytosis may be present. Extremity edema may or may not occur. Lower extremity SVT often involves one or more varicose veins.

Risk factors for SVT include increased age; pregnancy; obesity; malignancy; thrombophilia; estrogen therapy; recent sclerotherapy (e.g., treatment for varicose veins); long-distance travel; and a history of CVI, SVT, or VTE.[42] SVT also can occur in persons with endothelial alterations (e.g., Buerger's disease). SVT also may be unprovoked.

Collaborative Care. Duplex ultrasound is used to confirm the diagnosis (clot 5 cm or larger) and to rule out clot extension to a deep vein.[44,45] For patients with a lower leg SVT, treatment consists of low-molecular-weight heparin (LMWH) for 45 days or a prophylactic dose of fondaparinux (Arixtra).[44] If the SVT affects a very short vein segment (less than 5 cm) and is not near the saphenofemoral junction, anticoagulants may not be necessary and oral NSAIDs can ease symptoms. Additional interventions to relieve SVT symptoms include telling the patient to wear elastic compression stockings, apply topical NSAIDS, and perform mild exercise such as walking.[46]

Venous Thromboembolism

Clinical Manifestations. The patient with lower extremity VTE may or may not have unilateral leg edema, pain, tenderness with palpation, dilated superficial veins, a sense of fullness in the thigh or the calf, paresthesias, warm skin, erythema, or a systemic temperature greater than 100.4° F (38° C) (see Table 38-7). If the inferior vena cava is involved, both legs may be edematous and cyanotic. About 5% to 10% of VTEs involve the upper extremity veins and may extend into the internal jugular vein or superior vena cava.[44] If the superior vena cava is involved, similar symptoms may occur in the arms, neck, back, and face. Diagnosis of an initial VTE is based on clinical assessment combined with D-dimer testing and duplex ultrasound.[47]

Complications. The most serious complications of VTE are PE, post-thrombotic syndrome, and phlegmasia cerulea dolens. (See Chapter 28 for discussion of PE.)

Post-thrombotic syndrome (PTS) occurs in 20% to 50% of patients despite adequate anticoagulant therapy. It results from chronic venous hypertension caused by valvular destruction (from inflammation and scarring), stiff noncompliant vein walls, and persistent venous obstruction. Symptoms include pain, aching, heaviness, swelling, cramps, itching, and tingling.[48,49] Clinical signs include persistent edema, increased pigmentation, eczema, secondary varicosities, and *lipodermatosclerosis* (Fig. 38-10). Venous ulceration can occur with severe PTS. Manifestations of PTS typically begin within 2 years of a VTE.[48,49] Risk factors include persistent leg symptoms 1 month after VTE, VTE located near the iliofemoral junction, extensive VTE, recurrent VTE, obesity, older age, and female gender. Sequential compression devices (SCDs) may be used for patients with severe PTS.[50]

FIG. 38-10 Lipodermatosclerosis. Skin on lower leg becomes scarred, and the leg becomes tapered like an "inverted bottle." Hallmark signs of lipodermatosclerosis are leathery skin, brown discoloration, hyperpigmentation and hypopigmentation, and circumferential or near circumferential scarring and shrinking of the extremity.

Phlegmasia cerulea dolens (swollen, blue, painful leg), a rare complication, may develop in a patient in the advanced stages of cancer. It results from severe lower extremity VTE(s) that involve the major leg veins, causing near-total occlusion of venous outflow. Patients typically experience sudden, massive swelling; deep pain; and intense cyanosis of the extremity. If untreated, the venous obstruction causes arterial occlusion and gangrene and requires amputation.

Diagnostic Studies. Table 38-9 presents the various diagnostic studies used to determine the site or location and extent of a VTE.

Collaborative Care

Prevention and Prophylaxis. VTE prophylaxis is a core measure of high-quality health care in hospitalized surgical patients. The Joint Commission's core measures for the care of patients with VTE can be found at *www.jointcommission.org/core_measure_sets.aspx*. In addition, it is recommended that hospitals have a thromboprophylaxis policy that addresses VTE prevention on admission of all adult patients. As many as 60% of patients at risk for VTE do not receive appropriate thromboprophylaxis.[51]

In patients at risk for VTE, a variety of interventions are used. These are based on such factors as bleeding and thrombosis risk, past medical history, current medications, medical diagnoses, scheduled procedures, and patient preferences.[52] Early and aggressive mobilization based on the patient's condition is the easiest and most cost-effective method to decrease VTE risk. Patients on bed rest need to change position every 2 hours. Unless contraindicated, teach patients to flex and extend their feet, knees, and hips every 2 to 4 hours while awake. Patients who are able to get out of bed need to be in a chair for meals and ambulate at least four to six times per day as tolerated. Tell the patient and caregiver about the importance of these measures. Early and frequent ambulation is sufficient prophylaxis for very low VTE–risk patients undergoing minor surgical procedures.[53] Anticoagulation and mechanical prophylaxis

TABLE 38-9 DIAGNOSTIC STUDIES

Venous Thromboembolism*

Study	Description and Abnormal Findings
Blood Laboratory Studies	
ACT, aPTT, INR, bleeding time, Hgb, Hct, platelet count	Alterations if patient has underlying blood dyscrasia (e.g., increased Hgb and Hct in patient with polycythemia).
D-dimer	Fragment of fibrin formed as result of fibrin degradation and clot lysis. Elevated results suggest venous thromboembolism (VTE). *Normal results:* <250 ng/mL (<250 mcg/L)
Fibrin monomer complex	Forms when concentration of thrombin exceeds that of antithrombin. Presence is evidence of thrombus formation and suggests VTE. *Normal results:* <6.1 mg/L
Noninvasive Venous Studies	
Venous compression ultrasound	Evaluation of deep femoral, popliteal, and posterior tibial veins. *Normal finding:* Veins collapse with application of external pressure. *Abnormal finding:* Veins fail to collapse with application of external pressure. Failure to collapse suggests a thrombus.
Duplex ultrasound	Combination of compression ultrasound with spectral and color flow Doppler. Veins examined for respiratory variation, compressibility, and intraluminal filling defects to help determine location and extent of thrombus (most widely used test to diagnose VTE).
Invasive Venous Studies	
Computed tomography venography (CTV)	Uses spiral CT to evaluate veins in the pelvis, thighs, and calves after injection of venous phase contrast material. Uses less contrast material than traditional venography. May be performed simultaneously with CT angiography of pulmonary vessels for patients being evaluated for VTE.
Magnetic resonance venography	Uses magnetic resonance imaging with specialized software to evaluate blood flow through veins. Can be done with or without contrast. Highly accurate for pelvic and proximal veins. Less accurate for calf veins. Can distinguish acute and chronic thrombus.
Contrast venography (phlebogram)	X-ray determination of location and extent of clot using contrast media to outline filling defects. Identifies the presence of collateral circulation. Once the gold standard but currently rarely performed.

*See Table 28-26 for diagnostic studies for pulmonary embolism.
ACT, Activated clotting time; *aPTT,* activated partial thromboplastin time; *INR,* international normalized ratio.

are not recommended for acutely ill medical patients at low risk for VTE.

Elastic compression (antiembolism) stockings (e.g., thromboembolic deterrent [TED] hose) are a part of VTE prevention in hospitalized patients. When fitted correctly (both size and length) and worn properly and consistently from admission until discharge or full mobility, these stockings decrease VTE risk.[54] Proper use means the toe hole is under the toes, the heel patch is over the heel, the thigh gusset is on the inner thigh (thigh length only), and there are no wrinkles. The stockings are not to be rolled down, cut, or otherwise altered. Thigh-length stockings prevent proximal VTE better than knee-length stockings.[55] If the stockings are not fitted and worn correctly, venous return is impeded. This may promote the development of VTE and skin breakdown. VTE prevention is enhanced if elastic compression stockings are used along with anticoagulation.

Sequential compression devices (SCDs) are inflatable garments wrapped around the legs. They apply external pressure to the lower extremities by means of an electric pump. SCDs may or may not be used with elastic compression stockings. Like elastic compression stockings, ensure correct fit by accurately measuring the extremities. SCDs will not be effective if they are not applied correctly; if the fit is incorrect; or if the patient does not wear the device continuously except during bathing, skin assessment, and ambulation. SCDs are not worn when a patient has an active VTE because of the risk of PE. VTE prevention is enhanced if SCDs are used along with anticoagulation.[56]

Drug Therapy. Anticoagulants are used routinely for VTE prevention and treatment. The regimen depends on the patient's VTE risk. The goal of anticoagulant therapy for VTE prophylaxis is to prevent clot formation. The goals for treatment of a confirmed VTE are to prevent new clot development, spread of the clot, and embolization.[57]

Three major classes of anticoagulants are available: (1) vitamin K antagonists (VKA), (2) thrombin inhibitors (both indirect and direct), and (3) factor Xa inhibitors[58] (Table 38-10). Anticoagulant therapy does not dissolve the clot. Clot lysis begins naturally through the body's intrinsic fibrinolytic system (see Chapter 30).

Vitamin K Antagonists. The oral anticoagulant for long-term or extended anticoagulation is warfarin, a VKA. Warfarin inhibits activation of the vitamin K–dependent coagulation factors II, VII, IX, and X, as well as the anticoagulant proteins C and S. (Fig. 30-4 displays the clotting pathways, and clotting factors are listed in Table 30-2.) Warfarin begins to take effect in 48 to 72 hours. It then takes several more days to achieve a maximum effect. Thus an overlap of a parenteral anticoagulant (e.g., UH or LMWH) and warfarin typically is required for 5 days. The level of anticoagulation is monitored daily using the international normalized ratio (INR). The INR is a standardized system of reporting prothrombin time (PT) (Table 38-11, p. 852). The antidote for warfarin-related bleeding is vitamin K or Kcentra (Prothrombin Complex Concentrate [Human]).

Take a careful history before starting warfarin. Do not give antiplatelets or NSAIDs with warfarin, since these drugs

TABLE 38-10 DRUG THERAPY

Anticoagulant Therapy

Drug	Route of Administration	Comments
Vitamin K Antagonists (VKA)		
warfarin (Coumadin)	PO	INR is used for monitoring therapeutic levels. Administer at the same time each day. Variations of certain genes (e.g., *CYP2CP, VKORC1*) may influence response to the drug. *Antidote*: Vitamin K. For major VKA-related bleeding, treatment with four-factor prothrombin complex concentrate and IV vitamin K is recommended over fresh frozen plasma.
Thrombin Inhibitors: Indirect		
Unfractionated heparin (UH)	Continuous IV	Therapeutic effects measured at regular intervals by the aPTT or ACT. Monitor complete blood counts at regular intervals and titrate according to parameters.
heparin sodium (Hep-Lock, Liquaemin, Calciparine)	Intermittent IV Subcutaneous	If administering subcutaneously, inject deep into subcutaneous tissue (preferably into the abdominal fatty tissue or above the iliac crest), inserting the entire length of the needle. Hold skinfold during injection but release before removing needle. Do not aspirate. Do not inject intramuscularly. Do not rub site after injection. Rotate sites. *Antidote*: Protamine
Low-molecular-weight heparin (LMWH)	Subcutaneous	Routine coagulation tests typically not required. Monitor complete blood count at regular intervals. Do not expel air bubble before administering subcutaneously. Follow remaining administration guidelines as described above for UH. Reduced dosage needed in patients with renal impairment. Use extreme caution in patients with a history of HIT. *Antidote:* Protamine neutralizes the effects of LMWH.
enoxaparin (Lovenox)		
tinzaparin (Innohep)		
dalteparin (Fragmin)		
nadroparin (Fraxiparine)		
Thrombin Inhibitors: Direct		
Hirudin derivatives		Therapeutic effect measured by ACT or aPTT. Used in patients with HIT when anticoagulation is still required. *Antidote*: None
lepirudin (Refludan)	IV or subcutaneous	
bivalirudin (Angiomax)	IV	
desirudin (Iprivask)	IV or subcutaneous	
Synthetic thrombin inhibitors		Therapeutic effect measured by aPTT. Used in patients at risk for or with HIT. Used for VTE prevention in joint replacement surgery. VTE treatment option and for stroke prevention in nonvalvular atrial fibrillation. *Antidote:* None
argatroban (Acova)	IV	
dabigatran (Pradaxa)	Subcutaneous	
Factor Xa inhibitors		Routine coagulation tests not required. Monitor complete blood count and creatinine at regular intervals. Do not expel air bubble before administering. Follow remaining administration guidelines as described for UH. Both drugs approved for VTE prophylaxis and treatment. For surgical patients, initial dose should be given no earlier than 6 hr postoperatively. Use with caution in older patients and patients with impaired renal function. May cause thrombocytopenia. If uncontrollable bleeding occurs, treatment with recombinant factor VIIa may be effective. *Antidote:* None
fondaparinux (Arixtra)	Subcutaneous	
rivaroxaban (Xarelto)	PO	

ACT, Activated clotting time; *aPTT,* activated partial thromboplastin time; *HIT,* heparin-induced thrombocytopenia; *INR,* international normalized ratio; *VTE,* venous thromboembolism.

increase bleeding risk.[58] Many other drugs, vitamins, minerals, and dietary and herbal supplements also interact with warfarin (see eTable 38-1, available on the website for this chapter, and the Complementary & Alternative Therapies box on the right). A diet that frequently varies in vitamin K intake (e.g., green leafy vegetables) can make it hard to achieve and maintain a target INR level.

Genetic variants in the genes *VKORC1* and cytochrome P450 2C9 *(CYP2C9)* may influence how some people respond to warfarin (see Table 13-5). Although genetic testing is available, pharmacogenetic-based dosing is not recommended in clinical practice at this time.[59]

Thrombin Inhibitors: Indirect. *Indirect thrombin inhibitors* are divided into two major classes: UH and LMWHs. UH (e.g., heparin [Hep-Lock]) affects both the intrinsic and common pathways of blood coagulation by way of the plasma antithrombin. Antithrombin inhibits thrombin-mediated conversion of fibrinogen to fibrin by affecting factors II (prothrombin), IX, X, XI, and XII (see Fig. 30-4).

COMPLEMENTARY & ALTERNATIVE THERAPIES

Herbal and Dietary Supplements That May Affect Clotting

Scientific Evidence

There is evidence that the following herbs and dietary supplements may affect blood clotting: bilberry, black cohosh, chamomile, chondroitin sulfate, DHEA, feverfew, garlic, ginger, ginkgo biloba, ginseng, goldenseal, green tea, melatonin, niacin, omega-3 fatty acids, psyllium, red yeast rice extract, saw palmetto, soy, turmeric.

Nursing Implications

- Inform patients that taking these herbs, or dietary supplements may increase their risk of bleeding.
- Caution patients with bleeding disorders about the use of these herbs and dietary supplements. Advise them that they should consult with their health care provider before using these substances.

DHEA, Dehydroepiandrosterone.

TABLE 38-11 TESTS OF BLOOD COAGULATION

Drugs Monitored	Normal Value	Therapeutic Value
International normalized ratio (INR) Vitamin K antagonists (e.g., warfarin [Coumadin])	0.75-1.25	2-3
Activated partial thromboplastin time (aPTT)	25-35 sec	46-70 sec
• Unfractionated heparin (e.g., heparin [Hep-Lock])		
• Hirudin derivatives (e.g., bivalirudin [Angiomax])		
• Synthetic thrombin inhibitors (e.g., argatroban [Acova], dabigatran [Pradaxa])		
Activated clotting time (ACT)	70-120 sec*	>300 sec
• Unfractionated heparin		
• Hirudin derivatives		
• Synthetic thrombin inhibitors		
Anti–factor Xa		
• Low-molecular-weight heparin (e.g., enoxaparin [Lovenox])	0 U/mL	0.6-1.0 U/mL
• Factor Xa inhibitors (e.g., fondaparinux [Arixtra], rivaroxaban [Xarelto])	0 U/mL	0.2-1.5 U/mL

*Varies based on type of system and test reagent or activator used.

Heparin can be given subcutaneously for VTE prophylaxis or by continuous IV infusion for VTE treatment. When given IV, heparin requires frequent monitoring of clotting status as measured by activated partial thromboplastin time (aPTT) (see Table 38-11). Protamine sulfate reverses the effect of heparin.

One serious side effect of heparin is *heparin-induced thrombocytopenia* (HIT). HIT is an immune reaction to heparin. It causes a severe, sudden reduction in the platelet count along with a paradoxic increase in venous or arterial thrombosis. HIT is diagnosed by measuring the presence of heparin antibodies in the blood. Treatment requires immediately stopping heparin therapy and, if further anticoagulation is required, using a non-heparin anticoagulant (e.g., fondaparinux).[60] Another side effect of long-term heparin therapy is osteoporosis.

LMWHs (e.g., nadroparin [Fraxiparine]) are derived from UH. They have more bioavailability, more predictable dose response, longer half-life, and fewer bleeding complications than UH. LMWHs are less likely to cause HIT and osteoporosis. LMWHs typically do not require ongoing anticoagulant monitoring and dose adjustment. Protamine neutralizes the effect of LMWH.

Thrombin Inhibitors: Direct. *Direct thrombin inhibitors* are classified as hirudin derivatives or synthetic thrombin inhibitors. Hirudin is manufactured through recombinant deoxyribonucleic acid (DNA) technology. It binds specifically with thrombin and directly inhibits its function without causing plasma protein and platelet interactions. Hirudin derivatives (e.g., lepirudin [Refludan], bivalirudin [Angiomax]) are administered by continuous IV infusion. Lepirudin is approved for prophylaxis or treatment of patients with HIT. Bivalirudin is approved for HIT patients undergoing percutaneous coronary angioplasty. Anticoagulant activity is monitored using aPTT or activated clotting time (ACT) (see Table 38-11). There is no antidote for hirudin derivatives if bleeding occurs.

Argatroban (Acova), a synthetic direct thrombin inhibitor, inhibits thrombin. It is used as an alternative to heparin for the prevention and treatment of HIT and for known HIT patients who require percutaneous coronary interventions. Dabigatran (Pradaxa), an oral direct thrombin inhibitor, is used for VTE prevention after elective joint replacement, for stroke prevention in nonvalvular atrial fibrillation, and as a treatment option in VTE. The effects of argatroban and dabigatran are not reversible. Anticoagulant effect is monitored for both medications using aPTT or ACT.

Factor Xa Inhibitors. *Factor Xa inhibitors* inhibit factor Xa directly or indirectly, producing rapid anticoagulation. Fondaparinux is used for both VTE treatment and prophylaxis. It is given subcutaneously. Coagulation monitoring or dose adjustment is not needed, although the drug's anticoagulant activity can be measured using anti-Xa assays (see Table 38-11). If uncontrollable bleeding occurs, recombinant factor VIIa may be useful. Fondaparinux is contraindicated in patients with renal insufficiency. Rivaroxaban (Xarelto) is an oral factor Xa inhibitor used for VTE prevention.

Anticoagulant Therapy for VTE Prophylaxis. For VTE prophylaxis in the hospitalized medical patient at risk for thrombosis who is not bleeding, low-dose UH, LMWH, or fondaparinux is used. If the patient is at low VTE risk, drug prophylaxis is not needed. Patients with moderate VTE risk (e.g., general, gynecologic, urologic surgery) should receive either UH or LMWH. Patients with high VTE risk (e.g., trauma) should receive UH or LMWH until discharge. Patients having abdominal or pelvic surgery for cancer or major orthopedic surgery (e.g., total knee or hip replacement) should be prescribed VTE prophylaxis for up to 35 days after discharge.[59,61] (See eTable 38-2 for a sample VTE protocol/order set on the website for this chapter.)

Anticoagulant Therapy for VTE Treatment. Patients with confirmed VTE should receive initial treatment with either LMWH, UH, fondaparinux, or rivaroxaban. Oral VKA therapy is also started and continued for 3 months. A therapeutic INR is maintained between 2.0 and 3.0. Daily administration of only LMWH for 3 months is another option. Patients with multiple co-morbidities, complex medical issues, or a very large VTE usually are hospitalized for treatment. Parenteral administration of UH is the typical initial treatment. Depending on the

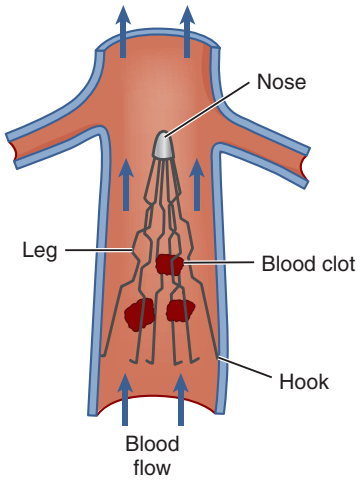

FIG. 38-11 Inferior vena caval interruption technique using Greenfield stainless steel filter to prevent pulmonary embolism. As blood travels up the vena cava, clots are trapped in the filter.

EVIDENCE-BASED PRACTICE

Applying the Evidence

You are caring for H.B., a 78-year-old Native American woman who is being discharged on enoxaparin (Lovenox) following a knee replacement. Her granddaughter will be her primary caregiver. You are preparing to teach her granddaughter how to inject the medication, since H.B. has limited dexterity in her hands because of arthritis. Her granddaughter tells you that H.B. is a modest woman and will not permit her to expose H.B.'s abdomen. She asks if the injection can be given in her arm.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Enoxaparin (per the package literature) should be administered by deep subcutaneous injection in the abdomen. Injection sites should be rotated.	Some patients have told you that they used alternate sites for injection of enoxaparin, specifically the thighs and upper arms. You do not have any evidence about the efficacy of the drug when alternate sites are used.	H.B. states she does not want to expose herself to her granddaughter. The granddaughter expresses a desire to support her grandmother's need for modesty.

Your Decision and Action

You discuss the importance of following the drug manufacturer's recommendations regarding site selection with H.B. and her granddaughter. You further explain that there is no evidence on whether alternate sites are equally effective. H.B.'s granddaughter states she is the only one available to do this and she needs to respect her grandmother's wishes. You teach the granddaughter how to inject enoxaparin in H.B.'s upper arms and to alternate the sites and arms. You inform the physician of H.B.'s decision and document your teaching and related conversation.

Lovenox. Retrieved from *www.lovenox.com/consumer/default.aspx*.

clinical presentation and home situation, patients may be safely and effectively managed as outpatients.

Thrombolytic Therapy for VTE Treatment. Another treatment option for patients with a thrombus is catheter-directed administration of a thrombolytic drug (e.g., urokinase, tPA). Catheter-directed thrombolysis dissolves the clot(s), reduces the acute symptoms, and decreases the incidence of PTS. Other catheter-based interventions such as angioplasty, stents, or mechanical thrombectomy can be used along with thrombolytic drug therapy. (Chapter 34 discusses thrombolytic therapy.)

Surgical Therapy. Although most patients are managed medically, a small number of patients undergo surgery. Surgical options include open venous thrombectomy and inferior vena cava interruption. *Venous thrombectomy* involves the removal of a thrombus through an incision in the vein. Anticoagulant therapy is recommended after venous thrombectomy.

Vena cava interruption devices (e.g., Greenfield, Vena Tech, TrapEase filters) can be inserted percutaneously through the right femoral or right internal jugular veins. The filter device is opened, and the spokes penetrate the vessel walls (Fig. 38-11). The filters act as a "sieve-type" device, permitting filtration of clots without interruption of blood flow. Complications after the insertion of the device are rare but include air embolism, improper placement, migration of the filter, and perforation of the vena cava with retroperitoneal bleeding. Over time, venous congestion can occur from a buildup of trapped clots. These can clog the filter and completely block the vena cava, requiring filter removal and replacement. A filter device is recommended with proximal VTE of the leg if anticoagulant therapy is contraindicated due to an increased risk of bleeding. Patients with a filter device are at increased risk of developing a VTE. If the bleeding risk resolves, a course of anticoagulant therapy is suggested.[62]

TABLE 38-12 NURSING ASSESSMENT

Venous Thromboembolism

Subjective Data

Important Health Information (see Table 38-8)

Past health history: Trauma to vein, intravascular catheter (e.g., peripherally inserted central catheter), varicose veins, pregnancy or recent childbirth, bacteremia, obesity, prolonged bed rest, irregular heartbeat (e.g., atrial fibrillation), COPD, HF, cancer, coagulation disorders and hypercoagulable states, systemic lupus erythematosus, MI, spinal cord injury, stroke, prolonged travel, recent bone fracture, dehydration

Medications: Use of estrogens (including oral contraceptives, hormone therapy), tamoxifen (Nolvadex), raloxifene (Evista), corticosteroids, excessive amounts of vitamin E, erythropoiesis-stimulating drugs

Surgery or other treatments: Any recent surgery, especially orthopedic, gynecologic, gastric, or urologic; previous surgery involving veins; central venous catheter

Functional Health Patterns

Health perception–health management: IV drug abuse, tobacco use, obesity

Activity-exercise: Inactivity

Cognitive-perceptual: Pain in area on palpation or ambulation

Objective Data

General

Fever, anxiety, pain

Integumentary

Increased size of extremity when compared with other side; taut, shiny, warm skin, erythematous, tender to palpation; no physical changes in the affected extremity in some patients

Cardiovascular

Distention and warmth of superficial veins in affected area; edema and cyanosis of extremities, neck, back, and face (if superior vena cava involvement)

Possible Diagnostic Findings

Leukocytosis, abnormal coagulation, anemia or ↑ hematocrit and RBC count, ↑ D-dimer level, positive venous compression on duplex ultrasound study; positive CTV, magnetic resonance venogram, or contrast venogram study

COPD, Chronic obstructive pulmonary disease; *CTV,* computed tomography venogram; *HF,* heart failure; *MI,* myocardial infarction; *RBC,* red blood cell.

NURSING MANAGEMENT VENOUS THROMBOEMBOLISM

NURSING ASSESSMENT

Table 38-12 presents the subjective and objective data to obtain from a patient with VTE.

NURSING DIAGNOSES

Nursing diagnoses and collaborative problems for the patient with VTE include, but are not limited to, the following:

- Acute pain *related to* venous congestion, impaired venous return, and inflammation

- Ineffective health maintenance *related to* lack of knowledge about disorder and its treatment
- Risk for impaired skin integrity *related to* altered peripheral tissue perfusion
- Potential complication: bleeding *related to* anticoagulant therapy
- Potential complication: PE *related to* embolization of thrombus, dehydration, and immobility

PLANNING

The overall goals for the patient with VTE include (1) pain relief, (2) decreased edema, (3) no skin ulceration, (4) no bleeding complications, and (5) no evidence of PE.

NURSING IMPLEMENTATION

ACUTE INTERVENTION. Focus your nursing care for the patient with VTE on prevention of emboli formation and reduction of inflammation. Review with the patient any medications, vitamins, minerals, and dietary and herbal supplements being taken that may interfere with anticoagulant therapy (see eTable 38-1 on the website for this chapter and the Complementary & Alternative Therapies box on p. 851). Depending on the anticoagulant ordered, monitor INR, aPTT, ACT, anti–factor Xa levels, complete blood count (CBC), creatinine, factor X levels, hemoglobin, hematocrit, platelet levels, and/or liver enzymes.[63] Monitor platelet counts for patients getting UH or LMWH to assess for HIT. Titrate doses of UH, warfarin, and direct thrombin inhibitors based on results of blood studies and physician-ordered parameters. Direct thrombin inhibitors may need adjustment for patients with renal or liver dysfunction. Always check the results of appropriate tests before starting, giving, or changing anticoagulant therapy.

DRUG ALERT: Anticoagulant Therapy

- Tell patient to avoid taking aspirin, NSAIDs, fish oil supplements, garlic supplements, ginkgo biloba, and certain antibiotics (e.g., sulfamethoxazole and trimethoprim [Bactrim]).
- Instruct patient to report any signs of bleeding (e.g., black or bloody stools, bloody urine, coffee-ground or bloody vomit, nosebleeds).
- Assess for signs of bleeding (e.g., hypotension, tachycardia, hematuria, melena, hematemesis, petechiae, ecchymosis).

Monitor for and reduce the risk of bleeding that may occur with anticoagulant therapy (Table 38-13). Be aware that the risk of bleeding is greater in persons receiving LMWH or UH with an active gastroduodenal ulcer, prior bleeding history, low platelet count, hepatic or renal failure, rheumatic disease, cancer, or age greater than 85 years.[64] Patients receiving warfarin with an INR of 5.0 or more are also at increased risk for bleeding. In the event of anticoagulation above target goals, give reversal agents (e.g., protamine, vitamin K) or make dosage adjustments as ordered. In the event of major VKA-related bleeding, rapid treatment with four-factor prothrombin complex concentrate and IV vitamin K is recommended over fresh frozen plasma.

SAFETY ALERT

- Observe closely for any signs of bleeding:
  - Epistaxis and bleeding gingivae
  - Blood (visible or occult) in emesis, urine, stool, sputum
  - Oozing or visible bleeding from trauma site or surgical incision
  - Excessive menstrual bleeding
- Monitor vital signs for changes: decreased BP, increased HR
- Avoid intramuscular (IM) injections.
- Assess for mental status changes, especially in the older patient, since this may indicate cerebral bleeding.

TABLE 38-13 NURSING INTERVENTIONS FOR PATIENTS TAKING ANTICOAGULANTS

Assessment

- Monitor vital signs as indicated.
- Examine urine and stool for overt and occult signs of blood.
- Inspect skin frequently, especially under any splinting devices.
- Evaluate platelet count for signs of heparin-induced thrombocytopenia.
- Evaluate appropriate laboratory coagulation tests for target therapeutic levels.
- Evaluate lower extremity for ecchymosis or hematoma development if sequential compression device used.
- Perform assessments frequently to observe for signs and symptoms of bleeding (e.g., hypotension, tachycardia) or clotting.
- Notify the health care provider of any abnormalities in assessments, vital signs, or laboratory values.

Injections

- Avoid intramuscular injections.
- Minimize venipunctures.
- Use small-gauge needles for venipunctures unless ordered therapy requires a larger gauge.
- Apply manual pressure for at least 10 min (or longer if needed) on venipuncture sites.

Patient Care

- Avoid restrictive clothing.
- Apply moisturizing lotion to skin.
- Use electric razors, not straight razors.
- Perform physical care in a gentle manner.
- Instruct patient not to forcefully blow nose.
- Avoid removing or disrupting established clots.
- Humidify O_2 source if supplemental O_2 is ordered.
- Use soft toothbrushes or foam swabs for oral care.
- Reposition the patient carefully at regular intervals.
- Limit tape application. Use paper tape as appropriate.
- Administer stool softeners to avoid hard stools and straining.
- Lubricate tubes (e.g., suction catheter) adequately before insertion.
- Avoid restraints if possible. Use only soft, padded restraints if needed.
- Use support pads, mattresses, bed cradles, and therapeutic beds as indicated.
- Apply elastic compression stockings or sequential compression devices as ordered and with attention to proper size, application, and use.
- Perform risk for fall and skin breakdown assessments per agency policy and implement safety measures as needed.

Early ambulation when compared with bed rest does not increase the short-term risk of a PE in patients with VTE. In addition, early ambulation after acute VTE results in a more rapid decrease in edema and limb pain, fewer PTS symptoms, and better quality of life. Teach the patient and caregiver the importance of physical activity and assist the patient to ambulate several times a day. For patients with acute VTE with severe edema and limb pain, bed rest with limb elevation may initially be prescribed.

AMBULATORY AND HOME CARE. Focus discharge teaching on modification of VTE risk factors, use of elastic compression stockings, importance of monitoring laboratory values, medication instructions, and guidelines for follow-up. Once the edema is resolved, measure the patient for custom-fit elastic compression stockings. Stocking use (or sleeves in the case of an upper

DELEGATION DECISIONS

Caring for the Patient With Venous Thromboembolism (VTE)

All members of the health care team have important roles in preventing and managing VTE.

Role of Registered Nurse (RN)

- Assess patients for VTE risk and monitor for VTE in at-risk patients.
- Develop a plan of care to prevent VTE.
- Teach hospitalized patients who are at risk for VTE about preventive measures such as increasing mobility, using elastic compression stockings and sequential compression devices, and taking anticoagulant medications.
- Assess for the use of dietary supplements or herbs that may affect the coagulation status before the initiation of anticoagulant therapy.
- Monitor for adverse effects of anticoagulant use.
- Evaluate the effect of anticoagulant medications by monitoring appropriate laboratory results.
- Assess for complications of VTE, including pulmonary embolism (PE) and chronic venous insufficiency.
- Provide discharge teaching about use of elastic compression stockings and anticoagulant medication instructions (including diet, necessary laboratory testing, and administration of subcutaneous anticoagulants if needed).
- Teach the patient and caregiver the clinical manifestations of PE and the need to contact the EMS if these occur.
- Teach safety precautions to prevent falls or other injuries that might result in bleeding.
- Provide instructions about the use of pressure to stop bleeding and that the EMS should be contacted for persistent bleeding.
- Teach the patient about lifestyle measures to prevent VTE, including leg exercises, ambulation, and avoidance of nicotine and oral contraceptives.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Administer prescribed oral, subcutaneous, and IV anticoagulants (consider state nurse practice act and agency policies regarding administration of high-alert medications and IV medications).
- Measure patients for elastic compression stockings and/or sequential compression devices.

Role of Unlicensed Assistive Personnel (UAP)

- Reposition patients who are on bed rest at least every 2 hr.
- Remind patients about the need to flex and extend the legs and feet every 2 hr while in bed.
- Assist ambulatory patients to ambulate at least 4 to 6 times daily.
- Assist patients with putting on elastic compression stockings.
- Apply sequential compression devices.

TABLE 38-14 PATIENT & CAREGIVER TEACHING GUIDE

Anticoagulant Therapy

Include the following information in the teaching plan for a patient receiving anticoagulant therapy and the patient's caregiver.

1. Give reasons for and action of anticoagulant therapy and how long therapy will last.
2. Take medication at the same time each day (preferably in afternoon or evening).
3. Depending on medication prescribed, obtain blood tests to assess therapeutic effect of the drug and whether change in drug dosage is needed.
4. Contact emergency medical services immediately for any of the following adverse side effects of drug therapy:
   - Blood in urine or stool; or black, tarry stools
   - Vomiting blood, coffee-ground emesis
   - Unusual bleeding from gums, skin, or nose, or heavy menstrual bleeding
   - Severe headaches or stomach pains
   - Chest pain, shortness of breath, palpitations (heart racing)
   - Weakness, dizziness, mental status changes
   - Cold, blue, or painful feet
5. Avoid any trauma or injury that might cause bleeding (e.g., vigorous brushing of teeth, contact sports, rollerblading, use of straight razor).
6. Avoid all aspirin-containing drugs and nonsteroidal antiinflammatory drugs.
7. Limit alcohol intake to small to moderate amounts (12 oz beer, 4 oz wine, 1 oz hard liquor/day).
8. Wear a Medic Alert device indicating what anticoagulant is being taken.
9. Avoid frequent changes in eating habits, such as dramatically increasing foods high in vitamin K (e.g., broccoli, spinach, kale, greens). Do not take supplemental vitamin K.
10. Consult with health care provider before beginning or discontinuing any medication, vitamin, mineral, or dietary or herbal supplement (see Complementary & Alternative Therapies box).
11. Inform all health care providers, including dentist, of anticoagulant therapy.
12. Correct dosing is essential. Provide supervision if patient experiences confusion or cognitive impairment.

extremity VTE) is recommended for at least 2 years after a VTE to support the vein walls and valves and decrease swelling and pain.[44,49] Regular use of elastic compression stockings reduces the incidence of mild PTS. Unfortunately, getting the patient to adhere to wearing stockings is a challenge. Address individual risk factors for VTE (e.g., obesity) and barriers to stocking use (e.g., lack of knowledge, depression) to improve patient adherence.[65]

If appropriate, tell the patient to stop smoking and avoid all nicotine products. Instruct the patient to avoid constrictive clothing. If appropriate, tell women with a history of VTE to stop oral contraceptives or HT. Teach patients to limit standing or sitting in a motionless, leg-dependent position. During long train or plane rides, encourage patients to frequently exercise the calf muscles and take short walks around the cabin. For those at high risk for VTE who are planning a long trip, recommend properly fitted, knee-high elastic compression stockings during travel to decrease edema and VTE risk. Aspirin or anticoagulant use is not suggested for long-distance travelers. Teach the patient and caregiver about signs and symptoms of PE such as sudden onset of dyspnea, tachypnea, and pleuritic chest pain. (Chapter 28 discusses PE.) They should contact EMS if these symptoms occur.

Instruct the patient and the caregiver about drug dosage, actions, and side effects; the need for routine blood tests; and what symptoms need immediate medical attention (Table 38-14). Devices are available for home monitoring of INR. Teach patients taking LMWH or fondaparinux and their caregivers how to give the drug subcutaneously. Active or young patients need to avoid contact sports and high-risk (for trauma) activities (e.g., skiing). Teach older patients about safety precautions to prevent falls (e.g., avoid use of throw rugs). Instruct the patient and caregiver to apply pressure for 10 to 15 minutes if bleeding occurs (e.g., nosebleed).

A well-balanced diet is important. Teach patients taking warfarin to follow a consistent diet of foods containing vitamin K and to avoid any supplements containing vitamin K (e.g., vitamins, green tea). Instruct the patient to avoid excessive amounts

of vitamin E and alcohol. Encourage proper hydration to prevent additional hypercoagulability of the blood, which may occur with dehydration.

The overweight patient needs to not only limit caloric intake but also increase physical activity to achieve and maintain desired weight. A balanced program of rest and exercise also improves venous return. Help the patient develop an exercise program with an emphasis on walking and swimming. Water exercise is particularly beneficial because of the gentle, even pressure of the water. A 6-month exercise program improves quality of life and reduces PTS.[66]

EVALUATION

The expected outcomes for the patient with VTE include

- Minimal to no pain
- Intact skin
- No signs of hemorrhage or occult bleeding
- No signs of respiratory distress

VARICOSE VEINS

Varicose veins, or *varicosities,* are dilated (3 mm or larger in diameter), tortuous subcutaneous veins commonly found in the saphenous vein system.[67] Varicosities may be small and harmless or large and bulging. *Primary varicose veins* (idiopathic) are due to a congenital weakness of the veins and are more common in women. *Secondary varicose veins* typically result from a previous VTE. Secondary varicose veins also may occur in the esophagus (esophageal varices), vulva, spermatic cords (varicoceles), and anorectal area (hemorrhoids), and as abnormal arteriovenous (AV) connections. *Reticular veins* are smaller varicose veins that appear flat, less tortuous, and blue-green in color. *Telangiectasias* (often referred to as spider veins) are small visible vessels (generally less than 1 mm in diameter) that appear bluish black, purple, or red.

Etiology and Pathophysiology

The etiology of varicose veins is multifactorial. Superficial veins in the lower extremities become dilated and tortuous in response to increased venous pressure. Risk factors include family history of venous disease, weakness of the vein structure, female gender, use of oral contraceptives or HT, tobacco use, increasing age, obesity, pregnancy, history of VTE, venous obstruction resulting from extrinsic pressure by tumors, thrombophilia, or occupations that require prolonged standing or sitting.[67] Although the exact etiology remains unknown, it is thought that the vein valve leaflets are stretched and become incompetent (do not fit together properly). Incompetent vein valves allow backward blood flow, particularly when the patient is standing. This results in increased venous pressure and further venous distention.

Clinical Manifestations and Complications

Discomfort from varicose veins varies among people and tends to be worse after episodes of SVT. Many patients are concerned about cosmetic disfigurement. The most common varicose vein symptoms include a heavy, achy feeling or pain after prolonged standing or sitting, which is relieved by walking or limb elevation. Some patients feel pressure or complain of an itchy, burning, tingling, throbbing, or cramplike leg sensation. Swelling, restless or tired legs, fatigue, and nocturnal leg cramps also may occur.

FIG. 38-12 **A,** Lateral aspect of varicose veins before treatment. **B,** Lateral aspect of varicose veins 2 years after initial treatment with sclerotherapy.

SVT is the most frequent complication of varicose veins. It may occur spontaneously or after trauma, surgical procedures, or pregnancy. Rare complications include rupture of the varicose veins resulting in external bleeding and skin ulcerations.

Diagnostic Studies and Collaborative Care

Superficial varicose veins can be diagnosed by appearance. A duplex ultrasound can detect obstruction and reflux in the venous system. Treatment usually is not indicated if varicose veins are only a cosmetic problem. If CVI develops, care involves rest with limb elevation; elastic compression stockings; and exercise, such as walking. Two herbal therapies used for varicose vein treatment are horse chestnut seed extract (HCSE) *(Aesculus hippocastanum)* and butcher's broom *(Ruscus aculeatus).*[68] Venoactive drugs (e.g., diosmin, hesperidin, rutosides [Venoruton]) with compression therapy are recommended for patients with varicose veins experiencing pain and swelling.

Sclerotherapy involves the injection of a substance (e.g., hypertonic saline, polidocanol, glycerine) that destroys venous telangiectasias, reticular veins, and superficial varicose veins 5 mm in diameter or smaller (Fig. 38-12). Direct IV injection of a sclerosing agent causes inflammation and results in thrombosis of the vein. This procedure is performed in an office setting and causes minimal discomfort. Potential complications include itching, pain, blistering, edema, inflammation, hyperpigmentation, tissue necrosis, recurrence of varicosities, SVT, and VTE.[69] After injection, a thigh-high elastic compression stocking is worn or an elastic bandage is applied to the leg for several days to maintain pressure over the vein. Long-term compression therapy is advised to help prevent further varicosities.

Other noninvasive options for the treatment of venous telangiectasias include laser therapy and high-intensity pulsed-light therapy. Laser or light therapy is used for isolated small telangiectasias or for patients in whom sclerotherapy is contraindicated or has been ineffective. Laser treatment typically requires more than one session, scheduled at 6- to 12-week intervals. Vascular lasers work by heating the hemoglobin in the vessels, resulting in vessel sclerosis. Potential complications of these therapies include pain, blistering, hyperpigmentation, and superficial erosions.

Surgical intervention is indicated for recurrent SVT or when CVI cannot be controlled with conservative therapy. The tradi-

tional surgical intervention involves ligation of the entire vein (usually the greater saphenous vein) and removal of its incompetent branches. An alternative but time-consuming technique is ambulatory phlebectomy. This involves pulling the varicosity through a "stab" incision followed by excision of the vein. Transilluminated powered phlebectomy involves the use of a tissue resector to destroy the varices and removes the pieces via aspiration. Potential complications include bleeding, bruising, and infection. In up to 30% of patients, a new vein forms to replace the one removed.

A less invasive procedure is endovenous ablation of the saphenous vein. Ablation involves the insertion of a catheter that emits energy. This causes collapse and sclerosis of the vein.[70] Potential complications include bruising, tightness along the vein, recanalization (reopening of the vein), and paresthesia. Endovenous ablation also may be done in combination with ligation or phlebectomy.

NURSING MANAGEMENT VARICOSE VEINS

Prevention is a key factor related to varicose veins. Instruct the patient to avoid sitting or standing for long periods, maintain ideal body weight, take precautions against injury to the extremities, avoid wearing constrictive clothing, and walk daily.

After vein ligation surgery, encourage the patient to deep breathe, which promotes venous return. Check the extremities regularly for color, movement, sensation, temperature, edema, and quality of pedal pulses. Some bruising and discoloration are normal. Postoperatively, elevate the legs 15 degrees to limit edema. Apply elastic compression stockings. Remove them every 8 hours for short periods and then reapply.

Long-term management of varicose veins is directed toward improving circulation and appearance, relieving discomfort, and avoiding complications and ulceration. Varicose veins can recur in other veins after surgery. Teach the patient the proper use and care of custom-fitted elastic compression stockings. The patient should apply stockings in bed before rising in the morning. Emphasize the importance of periodic positioning of the legs above the heart. The overweight patient may need assistance with weight loss. The patient with a job that requires long periods of standing or sitting needs to frequently flex and extend her or his hips, legs, and ankles and change positions.

CHRONIC VENOUS INSUFFICIENCY AND VENOUS LEG ULCERS

Chronic venous insufficiency (CVI), a common problem in women and older adults, is a condition that develops when leg veins and valves fail to keep blood moving forward. This results in *ambulatory venous hypertension*. CVI can lead to *venous leg ulcers* (formerly called *venous stasis ulcers* or *varicose ulcers*). Although CVI and venous leg ulcers are not life-threatening diseases, they are painful, debilitating, and costly conditions that adversely affect the quality of patients' lives.

Etiology and Pathophysiology

Both long-standing primary varicose veins and PTS can progress to CVI. As a result of ambulatory venous hypertension, serous fluid and RBCs leak from the capillaries and venules into the tissue. This produces edema and chronic inflammatory changes. Enzymes in the tissue eventually break down RBCs, causing the release of *hemosiderin,* which causes a brownish skin discoloration. Over time, the skin and subcutaneous tissue around the ankle are replaced by fibrous tissue, resulting in thick, hardened, contracted skin. Although the causes of CVI are known, the exact pathophysiology of venous leg ulcers is unknown.

FIG. 38-13 Venous leg ulcer.

Clinical Manifestations and Complications

In individuals with CVI the skin of the lower leg is leathery, with a characteristic brownish or "brawny" appearance from the hemosiderin deposition. Edema usually has been persistent for a prolonged period. Eczema, or "stasis dermatitis," is often present, and itching is a common complaint (see Table 38-1).

Venous ulcers classically are located above the medial malleolus (Fig. 38-13). The ulcer is often quite painful, particularly when edema or infection is present. Pain may be worse when the leg is in a dependent position. If the venous ulcer is untreated, the wound becomes wider and deeper, increasing the likelihood of infection. Severe complications can include osteomyelitis and malignant changes.[71] On rare occasions, severe CVI with long-standing nonhealing venous ulcers may result in the need for amputation.

Collaborative Care

Compression is essential for CVI treatment, venous ulcer healing, and prevention of ulcer recurrence. A variety of options are available for compression therapy. These include custom-fitted elastic compression stockings, elastic tubular support bandages, a Velcro wrap (CircAid), SCDs, a paste bandage (Unna boot) with an elastic wrap, and multilayer (three or four) bandage systems (e.g., Profore).[71] There are benefits to each type of compression therapy. Evaluate patients individually when choosing a compression method. Before starting compression therapy, assess the arterial status to make sure that PAD is not also present. An ABI of less than 0.9 suggests PAD, and the patient should not have high levels of compression therapy.

Moist environment dressings are the basis of wound care. A variety of these dressings are available, including transparent film dressings, hydrocolloids, hydrogels, foams, alginates, gauze, and combination dressings.[72] Dressing decisions should be based on wound characteristics, cost, and clinician judgment. (Chapter 12 and Table 12-10 discuss dressings.)

Evaluate the nutritional status of a patient with a venous ulcer. A balanced diet with adequate protein, calories, and nutrients is essential. Foods high in protein (e.g., meat, beans, cheese, tofu), vitamin A (green leafy vegetables), vitamin C (citrus fruits, tomatoes, cantaloupe), and zinc (meat, seafood) are most important for healing. For patients with diabetes, maintaining normal blood glucose levels assists the healing process.

Routine use of antibiotics is not indicated. Clinical signs of infection include change in quantity, color, or odor of the drainage; pus; erythema of the wound edges; change in sensation around the wound; warmth around the wound; increased local pain, edema, or both; dark-colored granulation tissue; induration around the wound; delayed healing; and cellulitis. If signs of infection occur, obtain a wound culture before starting antibiotic therapy. The usual treatment for infection is debridement, wound excision, and systemic antibiotics. A number of antimicrobial dressings (e.g., cadexomer iodine, silver) are available.

If the ulcer does not heal with conservative therapy, pentoxifylline or micronized purified flavonoid fraction (Daflon) is recommended with compression therapy to improve healing.[67] Other treatments may include coverage with a skin replacement or substitute such as split-thickness skin grafts, cultured keratinocyte grafts, or artificial bioengineered skin. When used with compression therapy, a bilayer artificial skin (e.g., Apligraf or Orcel) can increase ulcer healing more than a simple dressing and compression.[73] (Chapter 25 discusses skin grafting.) Although grafts may aid with healing, they do not replace the need for lifelong compression therapy.

An herbal therapy used for CVI treatment is horse chestnut seed extract (HCSE). Escins (the active ingredient) reduce leg pain, itching, and swelling.[68] Minor side effects associated with HCSE include dizziness, gastrointestinal complaints, headache, and pruritus. The value of HCSE in venous ulcer healing and recurrence is not known.

DELEGATION DECISIONS

Caring for the Patient With Chronic Venous Insufficiency

Many patients with chronic venous insufficiency and venous ulcers are cared for in an outpatient setting. In this case the registered nurse (RN) does an initial assessment of the wound, develops the plan of care, and periodically evaluates the patient and venous ulcer. Much of the routine wound care is done by unlicensed assistive personnel (UAP) and licensed practical/vocational nurses (LPN/LVNs).

Role of Registered Nurse (RN)

- Assess patients with venous insufficiency for increases in edema, stasis dermatitis, and venous stasis ulcers.
- Assess patient's diet and nutritional status and make referrals as necessary to a dietitian.
- Choose appropriate options for compression therapy and wound care.
- Evaluate for the effectiveness of therapies and need for alternative approaches.
- Teach patient and family about the pathophysiology, clinical manifestations, complications, and treatment of venous insufficiency.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Administer prescribed analgesics, antibiotics, or other medications.
- Apply compression devices.
- Provide wound care for chronic venous ulcers (consider state nurse practice act and agency policy).

Role of Unlicensed Assistive Personnel (UAP)

- Assist patients in elevating extremities to reduce edema and pain.
- Apply elastic wraps or compression stockings, as directed by the RN.
- Provide wound care for chronic venous ulcers (consider state nurse practice act and agency policy).

NURSING MANAGEMENT
CHRONIC VENOUS INSUFFICIENCY AND VENOUS LEG ULCERS

Long-term management of venous leg ulcers should focus on teaching the patient self-care measures. Demonstrate the correct application of elastic compression stockings, and have the patient "show back" the skill. Prescription elastic compression stockings should be worn daily to reduce the occurrence of CVI. Stress the importance of regular replacement every 4 to 6 months. Instruct the patient and caregiver to avoid trauma to the limbs, and teach them proper foot and leg care to avoid additional skin trauma. Patients with CVI have dry, flaky, itchy skin because of stasis dermatitis. Daily moisturizing decreases itching and prevents cracking of the skin. Venous dermatitis may result from contact with sensitizing products such as antibacterial agents (e.g., gentamicin); additives in bandages or dressings (e.g., adhesives); ointments containing lanolin, alcohols, or benzocaine; and over-the-counter creams or lotions with fragrance or preservatives.[71] Assess the wound for signs of infection with each dressing change.

Be certain to discuss activity guidelines and proper limb positioning. Instruct patients with CVI with or without a venous ulcer to avoid standing or sitting for long periods. Standing or sitting with the legs in a dependent position decreases blood flow to the lower extremities. Also instruct patients to frequently elevate their legs above the level of the heart to reduce edema. Encourage patients to begin a daily walking program once an ulcer heals.

CASE STUDY

Peripheral Artery Disease

iStockphoto/Thinkstock

Patient Profile

S.J., a 76-yr-old African American man, is admitted to the hospital with rest pain in both legs and a nonhealing ulcer of the big toe on the right foot.

Subjective Data

- History of a myocardial infarction, stroke, hypertension, heart failure, and type 1 diabetes mellitus
- Underwent a left femoral-popliteal bypass 5 yr ago
- Has a 45 pack-yr history of tobacco use
- Has been using insulin for 30 yr
- Complains of sudden, intense increase in right foot pain for past 2 hr
- Has slept in recliner with right leg in dependent position for several months

Current Medications

- furosemide 40 mg/day PO
- isosorbide dinitrate/hydralazine hydrochloride (BiDil) 1 tablet q8hr
- aspart (NovoLog) insulin with meals
- glargine insulin 50 U/day subcutaneously
- diltiazem sustained release 240 mg/day PO
- aspirin 325 mg/day PO
- Fish oil daily (self-prescribed)

Objective Data

Physical Examination

- BP 148/92 mm Hg; irregular apical HR 90/min, respiratory rate 22/min, temperature 97.9° F (36.6° C)
- Alert and oriented but anxious, no apparent physical or mental deficits from previous stroke
- Has a diminished right femoral pulse, popliteal pulse by Doppler only, posterior tibial pulse by Doppler only, and dorsalis pedis pulse absent (not palpable or present by Doppler); left leg pulses are weakly palpable
- Right leg ABI: 0.20; left leg ABI: 0.68
- Has a 2-cm necrotic ulcer on tip of right big toe
- Has thickened toenails; shiny, thin skin on legs; and hair absent on both lower legs
- Right foot is very cool, pale, and mottled in color with decreased sensation
- No peripheral edema present
- Bedside glucose measurement 298 mg/dL (last meal 4 hr before admission)

Discussion Questions

1. Assess S.J.'s risk factors for peripheral artery disease (PAD).
2. Differentiate S.J.'s signs and symptoms of chronic PAD and acute arterial ischemia.
3. Identify the possible cause(s) for the sudden, intense increase in right foot pain.
4. How would you interpret S.J.'s ABI findings?
5. What additional diagnostic tests can be performed to assess the extent of his PAD?
6. Given the physical examination data, what initial medication(s) would you expect the physician to prescribe?
7. What treatment modalities are possible for S.J.?
8. ***Priority Decision:*** What are the priority nursing responsibilities in caring for S.J.?
9. ***Delegation Decision:*** Identify activities that can be delegated to unlicensed assistive personnel.
10. ***Priority Decision:*** Based on the assessment data presented, what are the priority nursing diagnoses? Are there any collaborative problems?
11. ***Evidence-Based Practice:*** When teaching S.J., what evidence-based advice would you give him regarding the use of dietary supplements such as fish oil?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg.*

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A 50-year-old woman weighs 95 kg and has a history of tobacco use, high blood pressure, high sodium intake, and sedentary lifestyle. When developing an individualized care plan for her, the nurse determines that the most important risk factors for peripheral artery disease (PAD) that need to be modified are
   - **a.** weight and diet.
   - **b.** activity level and diet.
   - **c.** tobacco use and high blood pressure.
   - **d.** sedentary lifestyle and high blood pressure.
2. Rest pain is a manifestation of PAD that occurs due to a chronic
   - **a.** vasospasm of small cutaneous arteries in the feet.
   - **b.** increase in retrograde venous blood flow in the legs.
   - **c.** decrease in arterial blood flow to the nerves of the feet.
   - **d.** decrease in arterial blood flow to the leg muscles during exercise.
3. A patient with infective endocarditis develops sudden left leg pain with pallor, paresthesia, and a loss of peripheral pulses. The nurse's initial action should be to
   - **a.** elevate the leg to promote venous return.
   - **b.** start anticoagulant therapy with IV heparin.
   - **c.** notify the physician of the change in peripheral perfusion.
   - **d.** place the bed in reverse Trendelenburg to promote perfusion.
4. Which clinical manifestations are seen in patients with either Buerger's disease or Raynaud's phenomenon *(select all that apply)?*
   - **a.** Intermittent fevers
   - **b.** Sensitivity to cold temperatures
   - **c.** Gangrenous ulcers on fingertips
   - **d.** Color changes of fingers and toes
   - **e.** Episodes of superficial vein thrombosis
5. A patient is admitted to the hospital with a diagnosis of abdominal aortic aneurysm. Which signs and symptoms would suggest that his aneurysm has ruptured?
   - **a.** Sudden shortness of breath and hemoptysis
   - **b.** Sudden, severe low back pain and bruising along his flank
   - **c.** Gradually increasing substernal chest pain and diaphoresis
   - **d.** Sudden, patchy blue mottling on feet and toes and rest pain
6. Priority nursing measures after an abdominal aortic aneurysm repair include
   - **a.** assessment of cranial nerves and mental status.
   - **b.** administration of IV heparin and monitoring of aPTT.
   - **c.** administration of IV fluids and monitoring of kidney function.
   - **d.** elevation of the legs and application of elastic compression stockings.

7. The first priority of collaborative care of a patient with a suspected acute aortic dissection is to
   a. reduce anxiety.
   b. control blood pressure.
   c. monitor for chest pain.
   d. increase myocardial contractility.
8. The patient at highest risk for venous thromboembolism (VTE) is
   a. a 62-year-old man with spider veins who is having arthroscopic knee surgery.
   b. a 32-year-old woman who smokes, takes oral contraceptives, and is planning a trip to Europe.
   c. a 26-year-old woman who is 3 days postpartum and received maintenance IV fluids for 12 hours during her labor.
   d. an active 72-year-old man at home recovering from transurethral resection of the prostate for benign prostatic hyperplasia.
9. Which are probable clinical findings in a person with an acute lower extremity VTE *(select all that apply)?*
   a. Pallor and coolness of foot and calf
   b. Mild to moderate calf pain and tenderness
   c. Grossly diminished or absent pedal pulses
   d. Unilateral edema and induration of the thigh
   e. Palpable cord along a superficial varicose vein
10. The recommended treatment for an initial VTE in an otherwise healthy person with no significant co-morbidities would include
    a. IV argatroban (Acova) as an inpatient.
    b. IV unfractionated heparin as an inpatient.
    c. subcutaneous unfractionated heparin as an outpatient.
    d. subcutaneous low-molecular-weight heparin as an outpatient.
11. A key aspect of teaching for the patient on anticoagulant therapy includes which instructions?
    a. Monitor for and report any signs of bleeding.
    b. Do not take acetaminophen (Tylenol) for a headache.
    c. Decrease your dietary intake of foods containing vitamin K.
    d. Arrange to have blood drawn routinely to check drug levels.
12. In planning care and patient teaching for the patient with venous leg ulcers, the nurse recognizes that the most important intervention in healing and control of this condition is
    a. sclerotherapy.
    b. using moist environment dressings.
    c. taking horse chestnut seed extract daily.
    d. applying elastic compression stockings.

1. c, 2. c, 3. c, 4. b, c, d, 5. b, 6. c, 7. b, 8. b, 9. b, d, 10. d, 11. a, 12. d

CASE STUDY

Managing Multiple Patients

Introduction

You are working on the cardiovascular stepdown unit and have been assigned to care for the following six patients. You have one LPN and a UAP who are assigned to help you.

Patients

Jupiterimages/Banana-Stock/Thinkstock

L.P. is a 63-year-old Asian American man who was brought to the ED with complaints of chest pain, shortness of breath (SOB), palpitations, and dizziness. L.P.'s CK-MB and troponin levels are within normal limits. His ECG showed atrial fibrillation with a rapid ventricular response. He has been on IV diltiazem (Cardizem) and IV heparin for 24 hours. Although his heart rate has decreased to 102 bpm, the atrial fibrillation persists.

iStockphoto/Thinkstock

J.E. is a 70-year-old Hispanic woman admitted with complaints of increasing shortness of breath, fatigue, and weight gain. She has a systolic murmur and bilateral crackles. Her ejection fraction is 20%. She is currently receiving IV Lasix, oral potassium and enalapril (Vasotec), and a continuous infusion of nesiritide (Natrecor). She is receiving O_2 at 6 L per nasal cannula for an O_2 saturation greater than 93%. Her initial set of cardiac enzymes were normal.

iStockphoto/Thinkstock

D.M. is a 51-year-old white man who was rushed to the hospital by ambulance after experiencing crushing substernal chest pain that radiated down his left arm. His ECG demonstrated marked ST segment elevation in the inferior leads. Cardiac catheterization within 60 minutes of admission showed a 90% blockage of his LAD. Coronary angioplasty was performed and a stent inserted. He is now 2 days post-PTCA and has no recurrence of his chest pain.

Jupiterimages/Photos.com/Thinkstock

R.B. is a 50-year-old white man admitted for valvular heart disease with a history of IV drug use and alcohol abuse. He complains of chest pain with minimal exertion. He has atrial fibrillation with a rapid ventricular response. His rhythm converted to normal sinus rhythm after receiving IV amiodarone. Transesophageal echocardiography shows left atrial and ventricular hypertrophy and mitral and aortic regurgitation.

iStockphoto/Thinkstock

J.M. is a 68-year-old white man originally admitted 3 days ago with a diagnosis of acute decompensated HF. He had a cardiac arrest (pulseless VT) and was successfully defibrillated after one shock. He underwent electrophysiology studies, culminating in the implantation of an implantable cardiodefibrillator (ICD). He now is being treated for his heart failure.

iStockphoto/Thinkstock

S.J. is a 76-year-old African American man admitted with rest pain in both legs and a nonhealing ulcer of the big toe on the right foot. He has a history of an MI, stroke, hypertension, heart failure, and type 1 diabetes mellitus. He underwent a left femoral-popliteal bypass 5 years ago. His right foot is very cool, pale, and mottled in color with decreased sensation. He has a diminished right femoral pulse, a right popliteal and posterior tibial pulse by Doppler only, and his right dorsalis pedis pulse is absent (not palpable or present by Doppler). His left leg pulses are weakly palpable. His right leg ABI: 0.20; left leg ABI: 0.68.

Management Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Second? Provide a rationale for your decision.
2. ***Delegation Decision:*** Which tasks could you delegate to the UAP *(select all that apply)*?
   a. Monitor L.P.'s heparin infusion.
   b. Teach D.M. about activity restriction post-PTCA.
   c. Administer prescribed medications to R.B. and J.M.
   d. Report changes in pain or sensation of S.J.'s legs.
   e. Hook up J.M. to 12-lead ECG and monitor for any dysrhythmias.
3. ***Priority and Delegation Decision:*** As you are assessing L.P., the LPN informs you that S.J. is diaphoretic and complaining of chest pain. Which initial action would be most appropriate?
   a. Ask the LPN to notify S.J.'s health care provider.
   b. Have the LPN administer prescribed nitroglycerin to S.J.
   c. Leave L.P.'s room to perform a focused assessment on S.J.
   d. Finish assessing L.P. while the UAP obtains a 12-lead ECG on S.J.

Case Study Progression

S.J. rates his chest pain as a 9/10. His blood pressure is 110/70, heart rate 110, respiratory rate 26, and O_2 93% on room air. You obtain a 12-lead ECG and administer 0.4 mg SL nitroglycerin with minimal pain relief after 5 minutes. The 12-lead ECG demonstrates new ST elevation in leads II, III, and aVF.

4. Which interventions would you expect the health care provider to order for S.J. *(select all that apply)?*
   a. IV nitroglycerin
   b. IV morphine sulfate
   c. Emergent cardiac catheterization
   d. Furosemide 40 mg IV push STAT
   e. Increase O_2 flow rate to 12 L/minute
5. Which statement would you include in patient teaching regarding ICDs with J.M. and his family?
   a. Avoid air travel.
   b. Avoid driving for 6 weeks.
   c. Avoid any sexual activity in case the ICD discharges.
   d. Avoid standing near antitheft devices in doorways of stores and public buildings.
6. Knowing the mechanism of action for nesiritide, you prioritize monitoring of J.E.'s
   a. blood pressure.
   b. respiratory rate.
   c. b-Natriuretic peptide (BNP) level.
   d. troponin and CK-MB laboratory values.
7. ***Management Decision:*** You ask the UAP to take D.M.'s vital signs before and after having him walk 300 feet. When reviewing the patient's chart, you note documentation of the patient's walk but not his vital signs. What is your best initial action?
   a. Report the incident to the charge nurse for follow-up.
   b. Talk to the UAP to discuss why the vital signs were not documented.
   c. Walk D.M. yourself again and take his vital signs pre- and post-activity.
   d. Ask the LPN to ambulate D.M. and obtain his vital signs before and after.

LEARNING OUTCOMES

1. Describe the structures and functions of the organs of the gastrointestinal tract.
2. Describe the structures and functions of the liver, gallbladder, biliary tract, and pancreas.
3. Differentiate the processes of ingestion, digestion, absorption, and elimination.
4. Explain the processes of biliary metabolism, bile production, and bile excretion.
5. Link the age-related changes of the gastrointestinal system to the differences in assessment findings.
6. Select significant subjective and objective assessment data related to the gastrointestinal system that should be obtained from a patient.
7. Identify the appropriate techniques used in the physical assessment of the gastrointestinal system.
8. Differentiate normal from abnormal findings of a physical assessment of the gastrointestinal system.
9. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the gastrointestinal system.

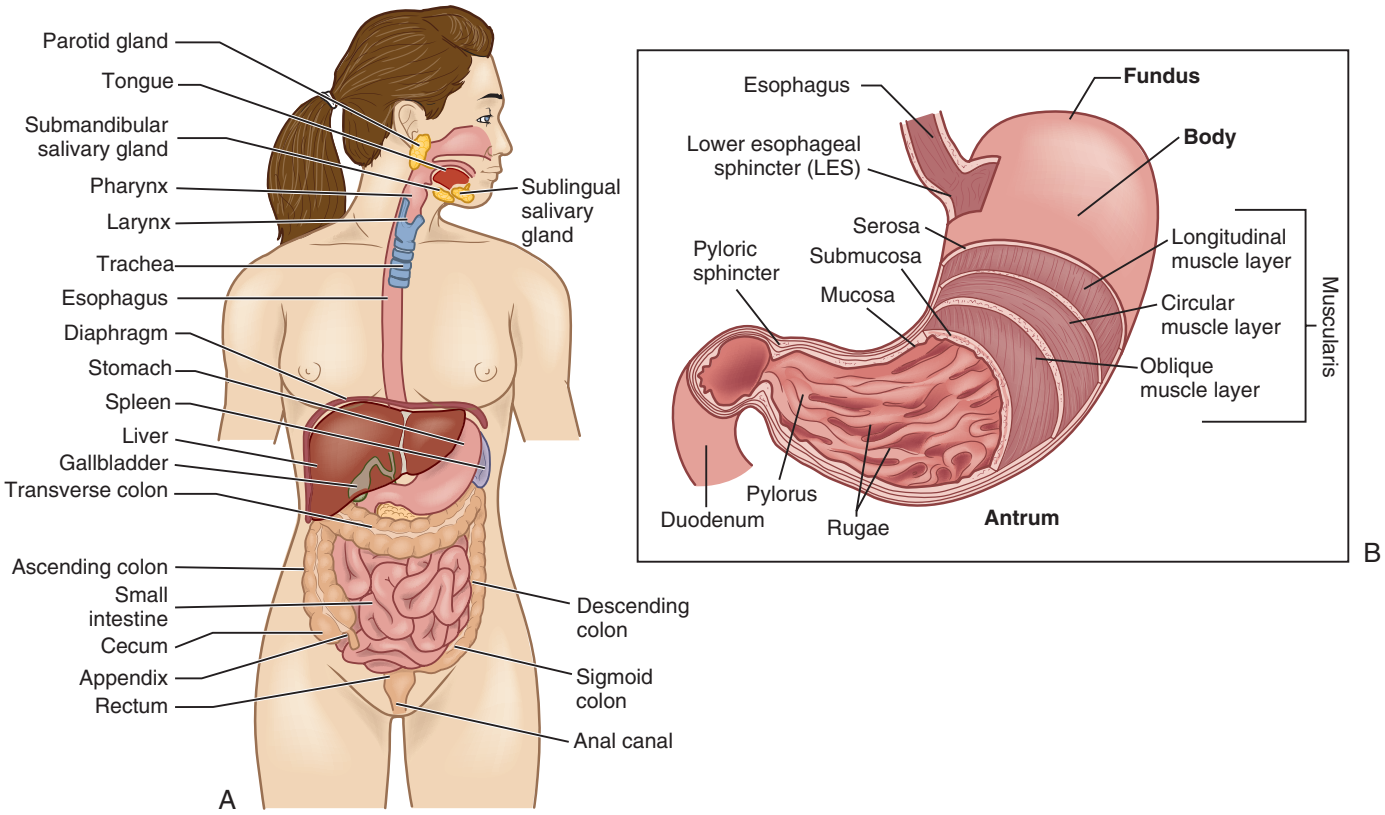

FIG. 39-1 **A,** Location of organs of the gastrointestinal system. **B,** Parts of the stomach.

The gastrointestinal (GI) system (also called the digestive system) consists of the GI tract and its associated organs and glands. Included in the GI tract are the mouth, esophagus, stomach, small intestine, large intestine, rectum, and anus. The associated organs are the liver, pancreas, and gallbladder (Fig. 39-1).

STRUCTURES AND FUNCTIONS OF GASTROINTESTINAL SYSTEM

The GI tract extends approximately 30 ft (9 m) from the mouth to the anus. It is composed of four common layers. From the inside to the outside, these layers are (1) mucosa, (2) submucosa, (3) muscle, and (4) serosa (see Fig. 39-1). The muscular coat consists of two layers: the circular (inner) layer and the longitudinal (outer) layer.

The GI tract is innervated by the parasympathetic and sympathetic branches of the autonomic nervous system. The parasympathetic (cholinergic) system is mainly excitatory, and the sympathetic (adrenergic) system is mainly inhibitory. For example, peristalsis is increased by parasympathetic stimulation and decreased by sympathetic stimulation. Sensory information is relayed via both sympathetic and parasympathetic afferent fibers.

The GI tract has its own nervous system: the enteric (or intrinsic) nervous system. The enteric nervous system is composed of two nerve layers that lie between the mucosa and the muscle layers. These neurons have receptors for pressure and movement.

The GI tract and accessory organs receive approximately 25% to 30% of the cardiac output at rest and 35% or more after eating. Circulation in the GI system is unique in that venous blood draining the GI tract organs empties into the portal vein, which then perfuses the liver. The vascular supply to the GI tract includes the celiac artery, superior mesenteric artery (SMA), and the inferior mesenteric artery (IMA). The stomach and duodenum receive their blood supply from the celiac axis. The distal small intestine to mid larger intestine receives its blood supply from branches of the hepatic and SMAs. The distal large intestine through the anus receives its blood supply from the IMA. Because such a large percentage of the cardiac output perfuses these organs, the GI tract is a major source from which blood flow can be diverted during exercise, stress, or injury.

The abdominal organs are almost completely covered by the peritoneum. The two layers of the peritoneum are the *parietal layer,* which lines the abdominal cavity wall, and the *visceral layer,* which covers the abdominal organs. The peritoneal cavity is the potential space between the parietal and visceral layers. The two folds of the peritoneum are the mesentery and the omentum. The mesentery attaches the small intestine and part of the large intestine to the posterior abdominal wall and contains blood and lymph vessels. The omentum hangs like an apron from the stomach to the intestines and contains fat and lymph nodes (see eFig. 39-1 on the website for this chapter).

The main function of the GI system is to supply nutrients to body cells. This is accomplished through the processes of (1) *ingestion* (taking in food), (2) *digestion* (breaking down food), and (3) *absorption* (transferring food products into circulation). *Elimination* is the process of excreting the waste products of digestion.

Ingestion

Ingestion is the intake of food. A person's appetite or desire to ingest food influences how much food is eaten. An appetite

center is located in the hypothalamus. It is directly or indirectly stimulated by hypoglycemia, an empty stomach, decrease in body temperature, and input from higher brain centers. The hormone *ghrelin* released from the stomach mucosa plays a role in appetite stimulation. Another hormone, *leptin,* is involved in appetite suppression. (Ghrelin and leptin are discussed in Chapter 41.) The sight, smell, and taste of food frequently stimulate appetite. Appetite may be inhibited by stomach distention, illness (especially accompanied by fever), hyperglycemia, nausea and vomiting, and certain drugs (e.g., amphetamines).

Deglutition (swallowing) is the mechanical component of ingestion. The organs involved in the deglutition of food are the mouth, pharynx, and esophagus.

Mouth. The mouth consists of the lips and the oral (buccal) cavity. The lips surround the orifice of the mouth and function in speech. The roof of the oral cavity is formed by the hard and soft palates. The oral cavity contains the teeth, used in mastication (chewing), and the tongue. The tongue is a solid muscle mass and assists in chewing and moving food to the back of the throat for swallowing. Taste receptors (taste buds) are found on the sides and tip of the tongue. The tongue is also important in speech.

Within the oral cavity are three pairs of salivary glands: the parotid, submaxillary, and sublingual glands. These glands produce saliva, which consists of water, protein, mucin, inorganic salts, and salivary amylase.

Pharynx. The pharynx is a musculomembranous tube that is divided into the nasopharynx, the oropharynx, and the laryngeal pharynx. The mucous membrane of the pharynx is continuous with the nasal cavity, mouth, auditory tubes, and larynx. The epiglottis is a lid of fibrocartilage that closes over the larynx during swallowing. During ingestion, the oropharynx provides a route for food from the mouth to the esophagus. When receptors in the oropharynx are stimulated by food or liquid, the swallowing reflex is initiated. The tonsils and the adenoids, composed of lymphoid tissue, assist the body in preventing infection.

Esophagus. The esophagus is a hollow, muscular tube that receives food from the pharynx and moves it to the stomach. It is 7 to 10 in (18 to 25 cm) long and 0.8 in (2 cm) in diameter. The esophagus is located in the thoracic cavity. The upper third of the esophagus is composed of striated skeletal muscle, and the distal two thirds are composed of smooth muscle.

With swallowing, the upper esophageal sphincter (cricopharyngeal muscle) relaxes and a peristaltic wave moves the bolus into the esophagus. Between swallows, the esophagus is collapsed. It is structurally composed of four layers: inner mucosa, submucosa, muscularis propria, and outermost adventitia.

The muscular layers contract *(peristalsis)* and propel the food to the stomach. There are two sphincters: the *upper esophageal sphincter* (UES) at the proximal end of the esophagus and the *lower esophageal sphincter* (LES) at the distal end. The LES remains contracted except during swallowing, belching, or vomiting. The LES is an important barrier that normally prevents reflux of acidic gastric contents into the esophagus.

Digestion and Absorption

Stomach. The stomach's functions are to store food, mix food with gastric secretions, and empty contents in small boluses into the small intestine. The stomach absorbs only small amounts of water, alcohol, electrolytes, and certain drugs.

The stomach is usually J shaped and lies obliquely in the epigastric, umbilical, and left hypochondriac regions of the abdomen (see Fig. 39-5 later in the chapter). It always contains gastric fluid and mucus. The three main parts of the stomach are the fundus (cardia), body, and antrum (see Fig. 39-1). The pylorus is a small portion of the antrum proximal to the pyloric sphincter. Sphincter muscles (the LES and the pyloric sphincter) guard the entrance to and exit from the stomach.

The serous (outer) layer of the stomach is formed by the peritoneum. The muscular layer consists of the longitudinal (outer) layer, circular (middle) layer, and oblique (inner) layer. The mucosal layer forms folds called *rugae* that contain many small glands. In the fundus the glands contain chief cells, which secrete pepsinogen, and parietal cells, which secrete hydrochloric (HCl) acid, water, and intrinsic factor. The secretion of HCl acid makes gastric juice acidic. This acidic pH aids in the protection against ingested organisms. Intrinsic factor promotes cobalamin (vitamin B_{12}) absorption in the small intestine.

Small Intestine. The two primary functions of the small intestine are digestion and *absorption* (uptake of nutrients from the gut lumen to the bloodstream). The small intestine is a coiled tube approximately 23 ft (7 m) in length and 1 to 1.1 in (2.5 to 2.8 cm) in diameter. It extends from the pylorus to the ileocecal valve. The small intestine is composed of the duodenum, jejunum, and ileum. The ileocecal valve prevents reflux of large intestine contents into the small intestine.

The mucosa of the small intestine is thick, vascular, and glandular. The functional units of the small intestine are *villi*, minute, fingerlike projections in the mucous membrane. They contain epithelial cells that produce the intestinal digestive enzymes. The epithelial cells on the villi also have *microvilli*. The circular folds in the mucous and submucous layers, along with the villi and microvilli, increase the surface area for digestion and absorption.

The digestive enzymes on the brush border of the microvilli chemically break down nutrients for absorption. The villi are surrounded by the crypts of Lieberkühn, which contain the multipotent stem cells for the other epithelial cell types. (Stem cells are discussed in Chapter 13.) Brunner's glands in the submucosa of the duodenum secrete an alkaline fluid containing bicarbonate. Intestinal goblet cells secrete mucus that protects the mucosa.

Physiology of Digestion. *Digestion* is the physical and chemical breakdown of food into absorbable substances. Digestion in the GI tract is facilitated by the timely movement of food through the GI tract and the secretion of specific enzymes. These enzymes break down foodstuffs to particles of appropriate size for absorption (Table 39-1).

The process of digestion begins in the mouth, where the food is chewed, mechanically broken down, and mixed with saliva. Approximately 1 L of saliva is produced each day. Saliva facilitates swallowing by lubricating food. Saliva contains amylase (ptyalin), which breaks down starches to maltose. Salivary gland secretion is stimulated by chewing movements and the sight, smell, thought, and taste of food. After swallowing, food is moved through the esophagus to the stomach. No digestion or absorption occurs in the esophagus.

In the stomach the digestion of proteins begins with the release of pepsinogen from chief cells. The stomach's acidic environment results in the conversion of pepsinogen to its active form, pepsin. Pepsin begins the breakdown of proteins. There is minimal digestion of starches and fats. The food is

mixed with gastric secretions, which are under neural and hormonal control (Tables 39-2 and 39-3). The stomach also serves as a reservoir for food, which is slowly released into the small intestine. The length of time that food remains in the stomach depends on the composition of the food, but average meals remain from 3 to 4 hours.

In the small intestine, carbohydrates are broken down to monosaccharides, fats to glycerol and fatty acids, and proteins to amino acids. The physical presence and chemical nature of *chyme* (food mixed with gastric secretions) stimulate motility and secretion. Secretions involved in digestion include enzymes from the pancreas, bile from the liver (see Table 39-1), and enzymes from the small intestine. Enzymes on the brush border of the microvilli complete the digestion process. These enzymes break down disaccharides to monosaccharides and peptides to amino acids for absorption.

Both secretion and motility are under neural and hormonal control. When food enters the stomach and small intestine, hormones are released into the bloodstream (see Table 39-3). These hormones play important roles in the control of HCl acid secretion, production and release of digestive enzymes, and motility.

Absorption is the transfer of the end products of digestion across the intestinal wall to the circulation. Most absorption occurs in the small intestine. The movement of the villi enables the end products of digestion to come in contact with the absorbing membrane. Monosaccharides (from carbohydrates), fatty acids (from fats), amino acids (from proteins), water, electrolytes, vitamins, and minerals are absorbed.

Elimination

Large Intestine. The large intestine is a hollow, muscular tube approximately 5 to 6 ft (1.5 to 1.8 m) long and 2 in (5 cm) in diameter. The four parts of the large intestine are shown in Fig. 39-2.

The most important function of the large intestine is the absorption of water and electrolytes. The large intestine also forms feces and serves as a reservoir for the fecal mass until defecation occurs. Feces are composed of water (75%), bacteria, unabsorbed minerals, undigested foodstuffs, bile pigments, and

TABLE 39-1 GASTROINTESTINAL SECRETIONS

Daily Amount (mL)	Secretions, Enzymes	Action
Salivary Glands		
1000-1500	Salivary amylase (ptyalin)	Initiation of starch digestion
Stomach		
2500	Pepsinogen	Protein digestion
	HCl acid	Activation of pepsinogen to pepsin
	Lipase	Fat digestion
	Intrinsic factor	Essential for cobalamin absorption in ileum
Small Intestine		
3000	Enterokinase	Activation of trypsinogen to trypsin
	Amylase	Carbohydrate digestion
	Peptidases	Protein digestion
	Aminopeptidases	Protein digestion
	Maltase	Maltose to two glucose molecules
	Sucrase	Sucrose to glucose and fructose
	Lactase	Lactose to glucose and galactose
	Lipase	Fat digestion
Pancreas		
700	Trypsinogen	Protein digestion
	Chymotrypsin	Protein digestion
	Amylase	Starch to disaccharides
	Lipase	Fat digestion
Liver and Gallbladder		
1000	Bile	Emulsification of fats and aid in absorption of fatty acids and fat-soluble vitamins (A, D, E, K)

TABLE 39-2 PHASES OF GASTRIC SECRETION

Stimulus to Secretion	Secretion
Cephalic (nervous)	
Sight, smell, taste of food (before food enters stomach). Initiated in the CNS and mediated by the vagus nerve.	HCl acid, pepsinogen, mucus
Gastric (hormonal and nervous)	
Food in antrum of stomach, vagal stimulation.	Release of gastrin from antrum into circulation to stimulate gastric secretions and motility
Intestinal (hormonal)	
Presence of chyme in small intestine.	*Acidic chyme* (pH <2): Release of secretin, gastric inhibitory polypeptide, cholecystokinin into circulation to decrease HCl acid secretion *Chyme* (pH >3): Release of gastrin from duodenum to increase acid secretion

TABLE 39-3 HORMONES CONTROLLING GI SECRETION AND MOTILITY

Hormone	Source	Activating Stimuli	Function
Gastrin	Gastric and duodenal mucosa	Stomach distention, partially digested proteins in pylorus	Stimulates gastric acid secretion and motility. Maintains lower esophageal sphincter tone.
Secretin	Duodenal mucosa	Acid entering small intestine	Inhibits gastric motility and acid secretion. Stimulates pancreatic bicarbonate secretion.
Cholecystokinin	Duodenal mucosa	Fatty acids and amino acids in small intestine	Contracts gallbladder and relaxes sphincter of Oddi. Allows increased flow of bile into duodenum; release of pancreatic digestive enzymes.
Gastric inhibitory peptide	Duodenal mucosa	Fatty acids and lipids in small intestine	Inhibits gastric acid secretion and motility.

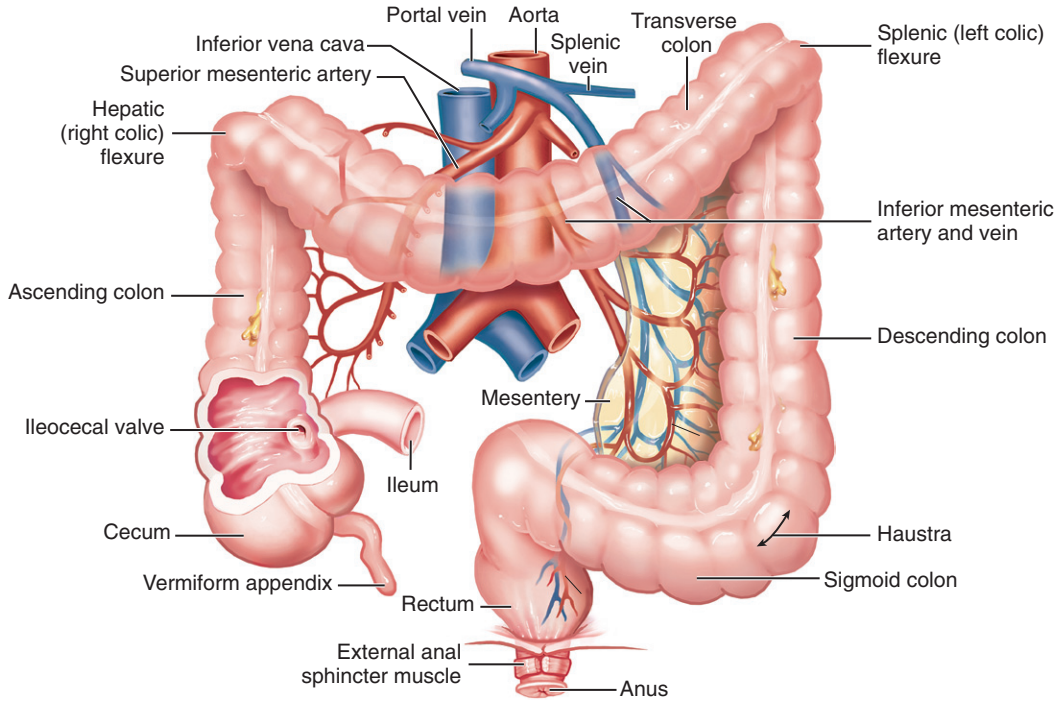

FIG. 39-2 Anatomic locations of the large intestine.

desquamated (shed) epithelial cells. The large intestine secretes mucus, which acts as a lubricant and protects the mucosa.

Microorganisms in the colon are responsible for the breakdown of proteins not digested or absorbed in the small intestine. These amino acids are deaminated by the bacteria, leaving ammonia, which is carried to the liver and converted to urea, which is excreted by the kidneys. Bacteria in the colon also synthesize vitamin K and some of the B vitamins. Bacteria also play a part in the production of flatus.

The movements of the large intestine are usually slow. However, propulsive (mass movements) peristalsis also occurs. When food enters the stomach and duodenum, gastrocolic and duodenocolic reflexes are initiated, resulting in peristalsis in the colon. These reflexes are more active after the first daily meal and frequently result in bowel evacuation.

Defecation is a reflex action involving voluntary and involuntary control. Feces in the rectum stimulate sensory nerve endings that produce the desire to defecate. The reflex center for defecation is in the sacral portion of the spinal cord (parasympathetic nerve fibers). These fibers produce contraction of the rectum and relaxation of the internal anal sphincter. Defecation is controlled voluntarily by relaxing the external anal sphincter when the desire to defecate is felt. An acceptable environment for defecation is usually necessary, or the urge to defecate will be ignored. If defecation is suppressed over long periods, problems can occur, such as constipation or fecal impaction.

Defecation can be facilitated by the **Valsalva maneuver.** This maneuver involves contraction of the chest muscles on a closed glottis with simultaneous contraction of the abdominal muscles. These actions result in increased intraabdominal pressure. The Valsalva maneuver may be contraindicated in the patient with a head injury, eye surgery, cardiac problems, hemorrhoids, abdominal surgery, or liver cirrhosis with portal hypertension.

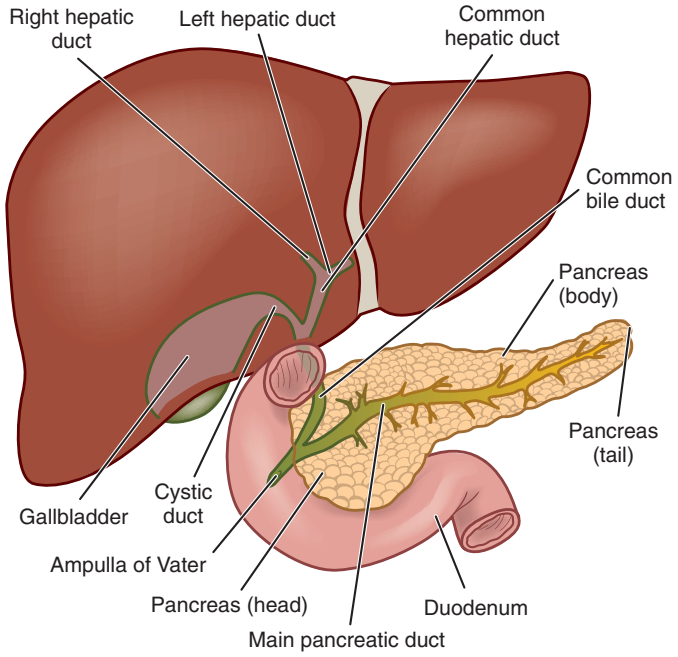

FIG. 39-3 Gross structure of the liver, gallbladder, pancreas, and duct system.

Liver, Biliary Tract, and Pancreas

Liver. The liver is the largest internal organ in the body, weighing approximately 3 lb (1.36 kg). It lies in the right epigastric region (see Fig. 39-5 later in the chapter). Most of the liver is enclosed in peritoneum. It has a fibrous capsule that divides it into right and left lobes (Fig. 39-3).

The functional units of the liver are lobules (see eFig. 39-2 on the website for this chapter). The lobule consists of rows of hepatic cells **(hepatocytes)** arranged around a central vein. The

capillaries (sinusoids) are located between the rows of hepatocytes and are lined with **Kupffer cells,** which carry out phagocytic activity (removal of bacteria and toxins from the blood). Interlobular bile ducts form from bile capillaries (canaliculi). The hepatic cells secrete bile into the canaliculi.

About one fourth of the blood supply comes from the hepatic artery (branch of the celiac artery), and three fourths comes from the portal vein. The portal circulatory system (enterohepatic) brings blood to the liver from the stomach, intestines, spleen, and pancreas. The portal vein carries absorbed products of digestion directly to the liver. In the liver the portal vein branches and comes in contact with each lobule.

The liver is essential for life. It functions in the manufacture, storage, transformation, and excretion of a number of substances involved in metabolism. The liver's functions are numerous and can be classified into four main areas (Table 39-4).

Biliary Tract. The biliary tract consists of the gallbladder and the duct system. The gallbladder is a pear-shaped sac located below the liver. The gallbladder's function is to concentrate and store bile. It holds approximately 45 mL of bile.

Bile is produced by the hepatic cells and secreted into the biliary canaliculi of the lobules. Bile then drains into the interlobular bile ducts, which unite into the two main left and right hepatic ducts. The hepatic ducts merge with the cystic duct from the gallbladder to form the common bile duct (see Fig. 39-3). Most of the bile is stored and concentrated in the gallbladder. It is then released into the cystic duct and moves down the common bile duct to enter the duodenum at the ampulla of Vater. In the intestines, bilirubin is reduced to stercobilinogen and urobilinogen by bacterial action. Stercobilinogen accounts for the brown color of stool. A small amount of conjugated bilirubin is reabsorbed into the blood. Some urobilinogen is reabsorbed into the blood, returned to the liver through the portal circulation (enterohepatic), and excreted in the bile.

Bilirubin Metabolism. **Bilirubin,** a pigment derived from the breakdown of hemoglobin, is constantly produced (Fig. 39-4). Because it is insoluble in water, it is bound to albumin for transport to the liver. This form of bilirubin is referred to as *unconjugated*. In the liver bilirubin is conjugated with glucuronic acid. *Conjugated* bilirubin is soluble and is excreted in bile. Bile also consists of water, cholesterol, bile salts, electrolytes, and phospholipids. Bile salts are needed for fat emulsification and digestion.

Pancreas. The pancreas is a long, slender gland lying behind the stomach and in front of the first and second lumbar vertebrae. It consists of a head, body, and tail. The anterior surface of the pancreas is covered by peritoneum. The pancreas contains lobes and lobules. The pancreatic duct extends along the gland and enters the duodenum through the common bile duct (see Fig. 39-3).

The pancreas has both exocrine and endocrine functions. The exocrine function contributes to digestion through the production and release of enzymes (see Table 39-1). The endocrine function occurs in the islets of Langerhans, whose β cells secrete insulin and amylin; α cells secrete glucagon; δ cells secrete somatostatin; and F cells secrete pancreatic polypeptide.

TABLE 39-4 FUNCTIONS OF THE LIVER

Function	Description
Metabolic Functions	
Carbohydrate metabolism	Glycogenesis (conversion of glucose to glycogen), glycogenolysis (process of breaking down glycogen to glucose), gluconeogenesis (formation of glucose from amino acids and fatty acids).
Protein metabolism	Synthesis of nonessential amino acids, synthesis of plasma proteins (except gamma globulin), synthesis of clotting factors, urea formation from ammonia (NH_3) (NH_3 formed from deamination of amino acids by action of bacteria in colon).
Fat metabolism	Synthesis of lipoproteins, breakdown of triglycerides into fatty acids and glycerol, formation of ketone bodies, synthesis of fatty acids from amino acids and glucose, synthesis and breakdown of cholesterol.
Detoxification	Inactivation of drugs and harmful substances and excretion of their breakdown products.
Steroid metabolism	Conjugation and excretion of gonadal and adrenal corticosteroid hormones.
Bile Synthesis	
Bile production	Formation of bile, containing bile salts, bile pigments (mainly bilirubin), and cholesterol.
Bile excretion	Bile excretion by liver about 1 L/day.
Storage	Glucose in form of glycogen. Vitamins, including fat soluble (A, D, E, K) and water soluble (B_1, B_2, cobalamin, folic acid). Fatty acids. Minerals (iron, copper). Amino acids in form of albumin and beta-globulins.
Mononuclear Phagocyte System	
Kupffer cells	Breakdown of old RBCs, WBCs, bacteria, and other particles. Breakdown of hemoglobin from old RBCs to bilirubin and biliverdin.

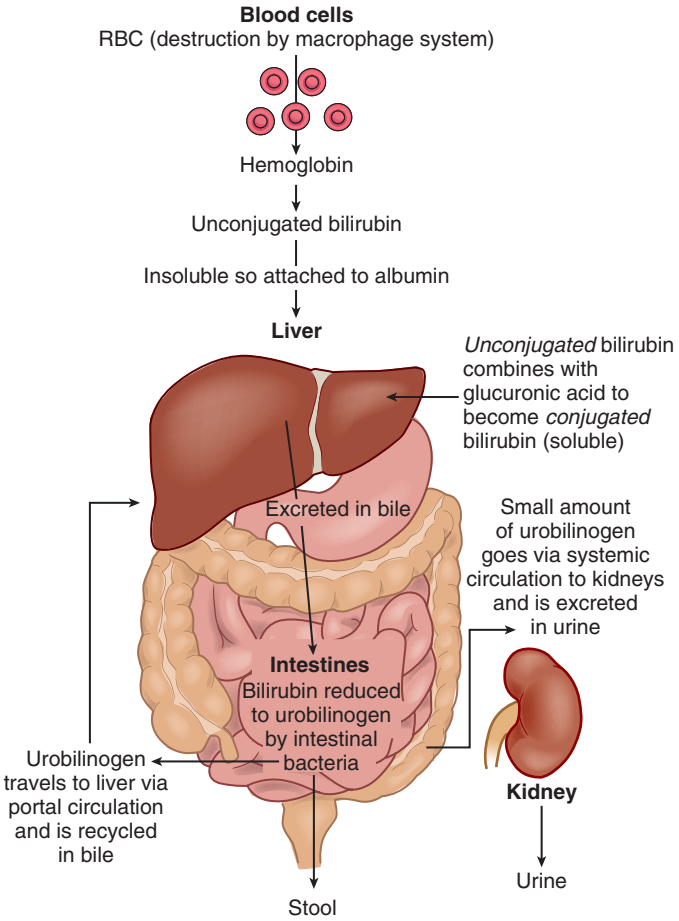

FIG. 39-4 Bilirubin metabolism and conjugation.

GERONTOLOGIC CONSIDERATIONS

EFFECTS OF AGING ON GASTROINTESTINAL SYSTEM

The process of aging changes the functional ability of the GI system (Table 39-5). Diet, alcohol intake, and obesity affect organs of the GI system, making it a challenge to separate the sole effects of aging from lifestyle. *Xerostomia* (decreased saliva production), or dry mouth, affects many older adults and may be associated with difficulty swallowing (dysphagia).[1] Many factors can lead to a decrease in appetite and make eating less pleasurable. These include a decrease in taste buds and salivary gland secretion, diminished sense of smell, and caries and periodontal disease leading to loss of teeth.

Age-related changes in the esophagus include delayed emptying resulting from smooth muscle weakness and an incompetent LES.[2] Although motility of the GI system decreases with age, secretion and absorption are affected to a lesser extent. The older patient often has a decrease in HCl acid secretion (hypochlorhydria) and a subsequent reduction in the amount of intrinsic factor secreted.

Although constipation is a common complaint of older adults, age-related changes in colonic secretion or motility have not been consistently shown.[3] Factors that may increase the risk for constipation include slower peristalsis, inactivity, decreased dietary fiber, decreased fluid intake, constipating medications, and laxative abuse; neurologic, cognitive, and metabolic disorders may also play a role.[4,5] (Constipation is discussed in Chapter 43.)

The liver size decreases after 50 years of age, but results of liver function tests remain within normal ranges. Age-related enzyme changes in the liver decrease the liver's ability to metabolize drugs and hormones.

The size of the pancreas is unaffected by aging, but it does undergo structural changes such as fibrosis, fatty acid deposits, and atrophy. Both obstructive and nonobstructive gallbladder diseases increase with age.[6]

Older adults, especially those over 85, are at risk for decreased food intake.[7] The economic inability to purchase food supplies affects nutritional intake, especially in the older adult. Economic constraints may also reduce the number of fresh fruits and vegetables consumed and thus the amount of fiber. Immobility limits the ability to obtain and prepare meals. In the United States, approximately one third of people over 60 are obese.[7,8] Age-related changes in the GI system and differences in assessment findings are presented in Table 39-5.

TABLE 39-5 GERONTOLOGIC ASSESSMENT DIFFERENCES

Gastrointestinal System

Expected Aging Changes	Differences in Assessment Findings
Mouth	
Gingival retraction	Loss of teeth, dental implants, dentures, difficulty chewing
Decreased taste buds, decreased sense of smell	Diminished sense of taste (especially salty and sweet)
Decreased volume of saliva	Dry oral mucosa
Atrophy of gingival tissue	Poor-fitting dentures
Esophagus	
Lower esophageal sphincter pressure decreased, motility decreased	Epigastric distress, dysphagia, potential for hiatal hernia and aspiration
Abdominal Wall	
Thinner and less taut	More visible peristalsis, easier palpation of organs
Decreased number and sensitivity of sensory receptors	Less sensitivity to surface pain
Stomach	
Atrophy of gastric mucosa, decreased blood flow	Food intolerances, signs of anemia as result of cobalamin malabsorption, slower gastric emptying
Small Intestines	
Slightly decreased motility and secretion of most digestive enzymes	Complaints of indigestion, slowed intestinal transit, delayed absorption of fat-soluble vitamins
Liver	
Decreased size and lowered position	Easier palpation because of lower border extending past costal margin
Decreased protein synthesis, ability to regenerate decreased	Decreased drug and hormone metabolism
Large Intestine, Anus, Rectum	
Decreased anal sphincter tone and nerve supply to rectal area	Fecal incontinence
Decreased muscular tone, decreased motility	Flatulence, abdominal distention, relaxed perineal musculature
Increased transit time, decreased sensation to defecation	Constipation, fecal impaction
Pancreas	
Pancreatic ducts distended, lipase production decreased, pancreatic reserve impaired	Impaired fat absorption, decreased glucose tolerance

ASSESSMENT OF GASTROINTESTINAL SYSTEM

Subjective Data

Important Health Information

Past Health History. Gather information from the patient about the history or existence of the following problems related to GI functioning: abdominal pain, nausea and vomiting, diarrhea, constipation, abdominal distention, jaundice, anemia, heartburn, dyspepsia, changes in appetite, hematemesis, food intolerance or allergies, indigestion, excessive gas, bloating, lactose intolerance, melena, trouble swallowing, hemorrhoids, or rectal bleeding. In addition, ask the patient about a history or existence of diseases such as reflux, gastritis, hepatitis, colitis, gallstones, peptic ulcer, cancer, diverticuli, or hernias.

Question the patient about weight history. Explore in detail any unexplained or unplanned weight loss or gain within the past 6 to 12 months. Document a history of chronic dieting and repeated weight loss and gain.

Medications. The health history should include an assessment of the patient's past and current use of medications. The names of all drugs, their frequency of use, and their duration of use are important. This is a critical aspect of history taking because many medications may not only have an effect on the GI system but also may be affected by abnormalities of the GI system. The medication assessment should include information about over-the-counter (OTC) medications, prescription

CASE STUDY

Patient Introduction

iStockphoto/Thinkstock

Patient Profile

L.C. is a 58-year-old Native American man from a Pueblo tribe in northern New Mexico. L.C.'s wife and family drove 50 miles to take him to the Indian Health Service hospital. He comes into the emergency department (ED) doubled over in pain. He is grimacing and holding his abdomen with both arms. You are working as the triage nurse that morning.

Critical Thinking

As you read through this chapter, think about L.C.'s symptoms with the following questions in mind:

1. What are the possible causes for L.C.'s acute abdominal pain?
2. What would be your priority assessment?
3. What questions would you ask L.C.?
4. What should be included in the physical assessment? What would you be looking for?
5. What diagnostic studies might you expect to be ordered?

- thiazolidinediones (e.g., pioglitazone [Actos])

drugs, herbal products, vitamins, and nutritional supplements (see the Complementary & Alternative Therapies box in Chapter 3 on p. 39). Note the use of prescription or OTC appetite suppressants.

Many chemicals and drugs are potentially hepatotoxic (Table 39-6) and result in significant patient harm unless monitored closely. For example, chronic high doses of acetaminophen and nonsteroidal antiinflammatory drugs (NSAIDs) may be hepatotoxic. NSAIDs (including aspirin) may also predispose a patient to upper GI bleeding, with an increasing risk as the person ages. Other medications such as antibiotics may change the normal bacterial composition in the GI tract, resulting in diarrhea. Antacids and laxatives may affect the absorption of certain medications. Ask the patient if laxatives or antacids are taken, including the kind and frequency.

Surgery or Other Treatments. Obtain information about hospitalizations for any problems related to the GI system. Also obtain data related to any abdominal or rectal surgery, including the year, reason for surgery, postoperative course, and possible blood transfusions. Terms related to surgery of the GI system are presented in Table 39-7.

Functional Health Patterns. Key questions to ask a patient with a GI problem are presented in Table 39-8.

Health Perception–Health Management Pattern. Ask about the patient's health practices related to the GI system, such as

TABLE 39-7 SURGERIES OF THE GASTROINTESTINAL SYSTEM

Procedure	Description
Appendectomy	Removal of appendix
Cholecystectomy	Removal of gallbladder
Choledochojejunostomy	Opening between common bile duct and jejunum
Choledocholithotomy	Opening into common bile duct for removal of stones
Colectomy	Removal of colon
Colostomy	Opening into colon
Esophagoenterostomy	Removal of portion of esophagus with segment of colon attached to remaining portion
Esophagogastrostomy	Removal of esophagus and anastomosis of remaining portion to stomach
Gastrectomy	Removal of stomach
Gastrostomy	Opening into stomach
Glossectomy	Removal of tongue
Hemiglossectomy	Removal of half of tongue
Herniorrhaphy	Removal of a hernia
Ileostomy	Opening into ileum
Mandibulectomy	Removal of mandible
Pyloroplasty	Enlargement and repair of pyloric sphincter area
Vagotomy	Resection of branch of vagus nerve

maintenance of normal body weight, proper dental care, adequate nutrition, and effective elimination habits.

Query the patient about recent foreign travel with possible exposure to hepatitis or parasitic infestation. Ask about potential risk behaviors for hepatitis C exposure. Document whether the patient has received hepatitis A and B vaccination.

Assess the patient for habits that directly affect GI functioning. The intake of alcohol in large quantities or for long periods has detrimental effects on the stomach mucosa. Chronic alcohol exposure causes fatty infiltration of the liver and can cause damage, leading to cirrhosis and hepatocellular carcinoma. Obtain a history of cigarette smoking. Nicotine is irritating to the GI tract mucosa. Cigarette smoking is related to GI cancers (especially mouth and esophageal cancers), esophagitis, and ulcers. Smoking delays the healing of ulcers.

GENETIC RISK ALERT: Colorectal Cancer

- Colorectal cancer may run in families if first-degree relatives (parents, siblings) or many other family members (grandparents, aunts, uncles) have had colorectal cancer. This is especially true when family members are diagnosed with colorectal cancer before age 50.
- Some genetic conditions associated with an increased risk of colorectal cancer include:
  - Hereditary nonpolyposis colorectal cancer (HNPCC), which is caused by mutations in several different genes.
  - Familial adenomatous polyposis (FAP), which is characterized by multiple polyps that are noncancerous at first, but eventually develop into cancer if not treated. Most cases of FAP are due to mutations of the adenomatous polyposis coli *(APC)* gene.

GENETIC RISK ALERT: Inflammatory Bowel Disease (IBD)

- People with IBD have a genetic predisposition or susceptibility to the disease.
- First-degree relatives have a 5- to 20-fold increased risk of developing IBD.

Family history is an important component of this health pattern. Because of the relationship between colorectal and breast cancer, inquire about a history of either type of cancer in the family. Women with HNPCC also have an increased risk of endometrial and ovarian cancer.

TABLE 39-8 HEALTH HISTORY

Gastrointestinal System

Health Perception–Health Management
- Describe any measures used to treat GI symptoms such as diarrhea or vomiting.
- Do you smoke?* Do you drink alcohol?*
- Are you exposed to any chemicals on a regular basis?* Have you been exposed in the past?*
- Have you recently traveled outside the United States?*

Nutritional-Metabolic
- Describe your usual daily food and fluid intake.
- Do you take any supplemental vitamins or minerals?*
- Have you experienced any changes in appetite or food tolerance?*
- Has there been a weight change in the past 6-12 mo?*
- Are you allergic to any foods?*

Elimination
- Describe the frequency and time of day you have bowel movements. What is the consistency of the bowel movement?
- Do you use laxatives or enemas?* If so, how often?
- Have there been any recent changes in your bowel pattern?*
- Describe any skin problems caused by GI problems.
- Do you need any assistive equipment, such as ostomy equipment, raised toilet seat, commode?

Activity-Exercise
- Do you have limitations in mobility that make it difficult for you to procure and prepare food?*

Sleep-Rest
- Do you experience any difficulty sleeping because of a GI problem?*
- Are you awakened by symptoms such as gas, abdominal pain, diarrhea, or heartburn?*

Cognitive-Perceptual
- Have you experienced any change in taste or smell that has affected your appetite?*
- Do you have any heat or cold sensitivity that affects eating?*
- Does pain interfere with food preparation, appetite, or chewing?*
- Do pain medications cause constipation, diarrhea, or appetite suppression?*

Self-Perception–Self-Concept
- Describe any changes in your weight that have affected how you feel about yourself.
- Have you had any changes in normal elimination that have affected how you feel about yourself?*
- Have any symptoms of GI disease caused physical changes that are a problem for you?*

Role-Relationship
- Describe the impact of any GI problem on your usual roles and relationships.
- Have any changes in elimination affected your relationships?*
- Do you live alone? Describe how your family or others assist you with your GI problems.

Sexuality-Reproductive
- Describe the effect of your GI problem on your sexual activity.

Coping–Stress Tolerance
- Do you experience GI symptoms in response to stressful or emotional situations?
- Describe how you deal with any GI symptoms that result.

Value-Belief
- Describe any culturally specific health beliefs regarding food and food preparation that may influence the treatment of your GI problem.

*If yes, describe.

Nutritional-Metabolic Pattern. A thorough nutritional assessment is essential. Take a diet history and inquire about both content and amount (portion size). Food preferences and preparation may vary by culture. Open-ended questions allow the patient to express beliefs and feelings about the diet. For example, you can say, "Please tell me about your food and beverage intake over the past 24 hours." A 24-hour dietary recall can be used to analyze the adequacy of the diet. Assist the patient in recalling the preceding day's food intake, including early morning and nighttime intake, snacks, liquids, and vitamin supplements. You can then evaluate the diet in relation to recommended servings. The U.S. Department of Agriculture released MyPlate *(www.choosemyplate.gov)* recommendations for dietary intake. A 1-week recall may provide additional information on usual dietary patterns. Compare weekday and weekend dietary intake patterns in relation to both the quality and quantity of food.

Ask the patient about the use of sugar and salt substitutes, use of caffeine, and amount of fluid and fiber intake. Note any changes in appetite, food tolerance, and weight. Anorexia and weight loss may indicate cancer or inflammation. Decreased food intake can also be the consequence of economic problems and depression.

Ask about food allergies and what GI symptoms occur with the allergic response. Inquire about dietary intolerances, including lactose and gluten.

Elimination Pattern. Elicit a detailed account of the patient's bowel elimination pattern. Note the frequency, time of day, and usual consistency of stool. Document the use of laxatives and enemas, including type, frequency, and results. Investigate any recent change in bowel patterns.

Document the amount and type of fluid and fiber intake because these influence the frequency and consistency of stools. Inadequate intake of fiber can be associated with constipation. Investigate the possible association between a skin problem and a GI problem. Food allergies can cause skin lesions, pruritus, and edema. Diarrhea can result in redness, irritation, and pain in the perianal area. External drainage systems, such as an ileostomy or ileal conduit, may cause local skin irritation.

Activity-Exercise Pattern. Activity and exercise affect GI motility. Immobility is a risk factor for constipation.

Assess ambulatory status to determine if the patient is capable of securing and preparing food. If the patient is unable to do these tasks, determine if a family member or an outside agency is meeting this need.

Note any limitation in patients' ability to feed themselves. Assess for access to a toilet. Identify the use of and access to supplies such as a commode or ostomy supplies.

Sleep-Rest Pattern. GI symptoms can interfere with the quality of sleep. Nausea, vomiting, diarrhea, indigestion, and bloating can produce sleep problems and should be investigated. Ask the patient if GI symptoms affect sleep or rest. For

example, a patient with gastroesophageal reflux disease (GERD) may be awakened because of burning, epigastric pain.

A patient may have a bedtime ritual that involves a particular food or beverage. Herbal teas may be sleep inducing. Document individual routines and comply with these whenever possible to avoid sleeplessness. Hunger can prevent sleep and should be relieved by a light, easily digested snack (unless contraindicated).

Cognitive-Perceptual Pattern. Sensory alterations can result in problems related to the acquisition, preparation, and ingestion of food. Changes in taste or smell can affect appetite and eating pleasure. Vertigo can make shopping and standing at a stove difficult and dangerous. Heat or cold sensitivity can make certain foods painful to eat. Problems in expressive communication limit the patient's ability to state personal dietary preferences. If a patient is diagnosed as having a GI disorder, ask questions to determine his or her understanding of the illness and its treatment.

Both acute and chronic pain influence dietary intake. Behaviors associated with pain include avoidance of activity, fatigue, and disruption of eating patterns. Assess patients receiving opioid medications for constipation, nausea, sedation, and appetite suppression.

Self-Perception–Self-Concept Pattern. Many GI and nutritional problems affect the patient's self-perception. Overweight and underweight persons may have problems related to self-esteem and body image. Repeated attempts to achieve a personally acceptable weight can be discouraging and depressing for some people. The way a person recounts a weight history can alert you to potential problems in this area.

The need for external devices to manage elimination, such as a colostomy or an ileostomy, may be challenging for some patients. The patient's willingness to engage in self-care and to discuss this situation provides you with valuable information related to body image and self-esteem.

The altered physical changes often associated with advanced liver disease can be disturbing for the patient. Jaundice and ascites cause significant changes in external appearance. Assess the patient's attitude toward these changes.

Role-Relationship Pattern. Problems related to the GI system such as cirrhosis, hepatitis, ostomies, obesity, and carcinoma may alter the patient's ability to maintain usual roles and relationships. A chronic illness may necessitate leaving a job or reducing work hours. Changes in body image and self-esteem can affect relationships.

Sexuality-Reproductive Pattern. Changes related to sexuality and reproductive status can result from problems of the GI system. For example, obesity, jaundice, anorexia, and ascites could decrease the acceptance of a potential sexual partner. An ostomy could affect the patient's confidence related to sexual activity. Your sensitive questioning can identify potential problems.

Anorexia can affect the reproductive status of a female patient. Obesity leads to reduced fertility and increased miscarriage rates in women.[9]

Coping–Stress Tolerance Pattern. Determine what is stressful for the patient and what coping mechanisms the patient uses. Factors outside the GI tract can influence its functioning. Both psychologic and emotional factors, such as stress and anxiety, influence GI functioning in many people. Stress may be manifested as anorexia, nausea, epigastric and abdominal pain, or diarrhea. Some diseases of the GI system, such as peptic ulcer disease, IBS, and IBD, may be aggravated by stress. However, GI symptoms should never be attributed solely to psychologic factors.

Value-Belief Pattern. Assess the patient's spiritual and cultural beliefs regarding food and food preparation. Whenever possible, respect these preferences. Determine if any value or belief could interfere with planned interventions. For example, if the patient with anemia is a vegetarian, the prescription of a high-meat diet would be resisted. Thoughtful assessment and consideration of the patient's beliefs and values usually increase adherence and satisfaction.

CASE STUDY—cont'd

Subjective Data

iStockphoto/Thinkstock

A focused subjective assessment of L.C. revealed the following information:

- ***PMH:*** Negative history for medical or surgical problems.
- ***Medications:*** None.
- ***Health Perception–Health Management:*** L.C. states he has not been feeling well for the past several weeks. He feels weak and is easily fatigued. Denies exposure to chemicals. No recent travel outside of the United States. Smokes approximately 1 pack of cigarettes/day for 20 yr. Drinks beer on a daily basis, typically three or four bottles per day.
- ***Nutritional-Metabolic:*** L.C. is 5 ft, 9 in tall and weighs 140 lb (BMI: 20.7 kg/m^2). States has been losing weight over the past several months and does not have an appetite. No food allergies.
- ***Elimination:*** States has had alternating episodes of constipation and diarrhea. He noticed some bright red blood in stools. Has not had a bowel movement for 4 days.
- ***Cognitive-Perceptual:*** Rates pain as a 9 on a scale of 0-10. States pain comes and goes in waves. Prefers to lie still with knees flexed and drawn into his abdomen.

Objective Data

Physical Examination

Mouth

Inspection. Inspect the mouth for symmetry, color, and size. Observe for abnormalities such as pallor or cyanosis, cracking, ulcers, or fissures. The dorsum (top) of the tongue should have a thin white coating; the undersurface should be smooth. Observe for any lesions. Using a tongue blade, inspect the buccal mucosa and note the color, any areas of pigmentation, and any lesions. Dark-skinned individuals normally have patchy areas of pigmentation. In assessing the teeth and gums, look for caries; loose teeth; abnormal shape and position of teeth; and swelling, bleeding, discoloration, or inflammation of the gingivae. Note any distinctive breath odor.

Inspect the pharynx by tilting the patient's head back and depressing the tongue with a tongue blade. Observe the tonsils, uvula, soft palate, and anterior and posterior pillars. Instruct the patient to say "ah." The uvula and soft palate should rise and remain in the midline.

Palpation. Palpate any suspicious areas in the mouth. Note ulcers, nodules, indurations, and areas of tenderness. The mouth of the older adult requires careful assessment. Give particular attention to dentures (e.g., fit, condition), ability to swallow, the tongue, and lesions. Ask the patient with dentures to remove them during an oral examination to allow for good visualization and palpation of the area.

Abdomen. Two systems are used to anatomically describe the surface of the abdomen. One system divides the abdomen

TABLE 39-9 STRUCTURES LOCATED IN ABDOMINAL REGIONS

Right Upper Quadrant	Left Upper Quadrant	Right Lower Quadrant	Left Lower Quadrant
• Liver and gallbladder	• Left lobe of liver	• Lower pole of right kidney	• Lower pole of left kidney
• Pylorus	• Spleen	• Cecum and appendix	• Sigmoid flexure
• Duodenum	• Stomach	• Portion of ascending colon	• Portion of descending colon
• Head of pancreas	• Body of pancreas	• Bladder (if distended)	• Bladder (if distended)
• Right adrenal gland	• Left adrenal gland	• Right ovary and salpinx	• Left ovary and salpinx
• Portion of right kidney	• Portion of left kidney	• Uterus (if enlarged)	• Uterus (if enlarged)
• Hepatic flexure of colon	• Splenic flexure of colon	• Right spermatic cord	• Left spermatic cord
• Portion of ascending and transverse colon	• Portion of transverse and descending colon	• Right ureter	• Left ureter

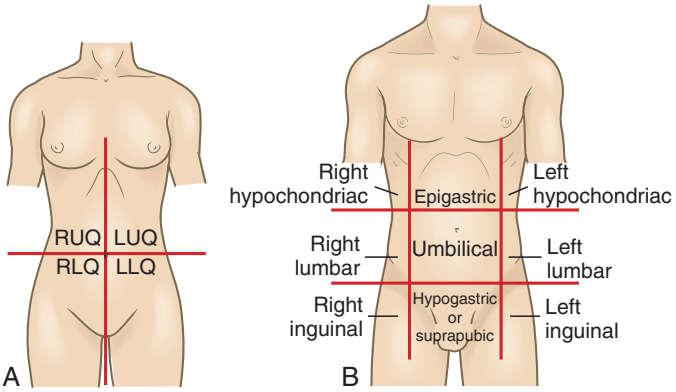

FIG. 39-5 **A,** Abdominal quadrants. **B,** Abdominal regions. *LLQ,* Left lower quadrant; *LUQ,* left upper quadrant; *RLQ,* right lower quadrant; *RUQ,* right upper quadrant.

into four quadrants by a perpendicular line from the sternum to the pubic bone and a horizontal line across the abdomen at the umbilicus (Fig. 39-5, *A*, and Table 39-9). The other system divides the abdomen into nine regions (Fig. 39-5, *B*), but only the epigastric, umbilical, and suprapubic or hypogastric regions are commonly assessed.

For the abdominal examination, good lighting should shine across the abdomen. The patient should be in the supine position and as relaxed as possible. To help relax the abdominal muscles, have the patient slightly flex the knees and raise the head of the bed slightly. The patient should have an empty bladder. Use warm hands when doing the abdominal examination to avoid eliciting muscle guarding. Ask the patient to breathe slowly through the mouth.

Inspection. Assess the abdomen for skin changes (color, texture, scars, striae, dilated veins, rashes, lesions), umbilicus (location and contour), symmetry, contour (flat, rounded [convex], concave, protuberant, distention), observable masses (hernias or other masses), and movement (pulsations and peristalsis). A normal aortic pulsation may be seen in the epigastric area. Look across the abdomen tangentially (across the abdomen in a line) for peristalsis. Peristalsis is not normally visible in an adult but may be visible in a thin person.

Auscultation. During examination of the abdomen, auscultate before percussion and palpation because these latter procedures may alter the bowel sounds. Use the diaphragm of the stethoscope to auscultate bowel sounds because they are relatively high pitched. Use the bell of the stethoscope to detect lower-pitched sounds. Warm the stethoscope in your hands before auscultating to help prevent abdominal muscle contraction. Listen in the epigastrium and in all four quadrants (start in the lower right quadrant). Listen for bowel sounds for at least

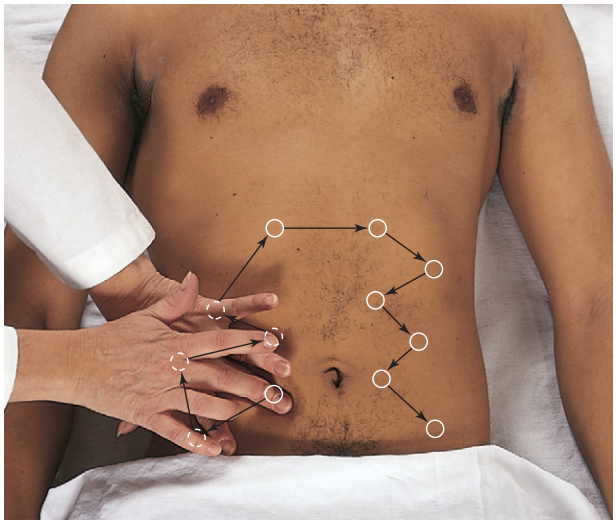

FIG. 39-6 Technique for percussion of the abdomen. Moving clockwise, percuss lightly in all four quadrants. From Jarvis C: *Physical examination and health assessment,* ed 6, St Louis, 2012, Saunders.

2 minutes. A perfectly "silent abdomen" is uncommon.[10] If you are patient and listen for several minutes, you will frequently find that the sounds are not absent but are hypoactive. If you do not hear bowel sounds, note the amount of time you listened in each quadrant without hearing bowel sounds.

The frequency and intensity of bowel sounds vary depending on the phase of digestion. Normal sounds are relatively high pitched and gurgling. Loud gurgles indicate hyperperistalsis and are termed *borborygmi* (stomach growling). The bowel sounds are more high pitched (rushes and tinkling) when the intestines are under tension, as in intestinal obstruction. Listen for decreased or absent bowel sounds. Terms used to describe bowel sounds include *present, absent, increased, decreased, high pitched, tinkling, gurgling,* and *rushing.*

Also listen for vascular sounds. Normally no aortic bruits should be heard. A *bruit,* best heard with the bell of the stethoscope, is a swishing or buzzing sound and indicates turbulent blood flow.

Percussion. The purpose of percussion of the abdomen is to estimate the size of the liver and determine the presence of fluid, distention, and masses. Sound waves vary according to the density of underlying tissues. Air produces a higher-pitched, hollow sound termed *tympany.* Fluid or masses produce a short, high-pitched sound with little resonance termed *dullness.* Lightly percuss all four quadrants of the abdomen and assess the distribution of tympany and dullness (Fig. 39-6). Tympany is the predominant percussion sound of the abdomen.

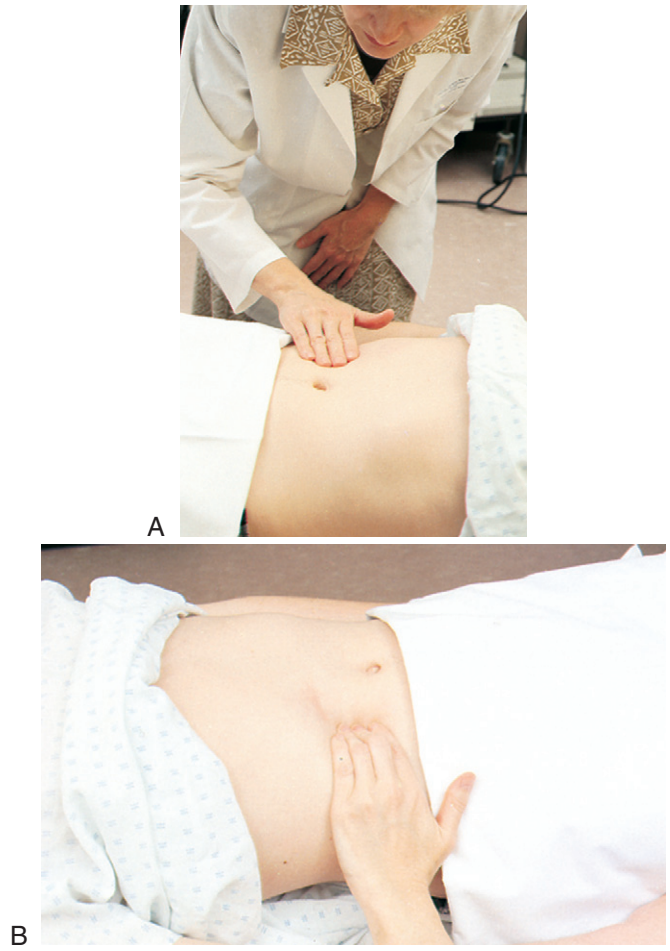

FIG. 39-7 A, Technique for light palpation of the abdomen. **B,** Technique for deep palpation.

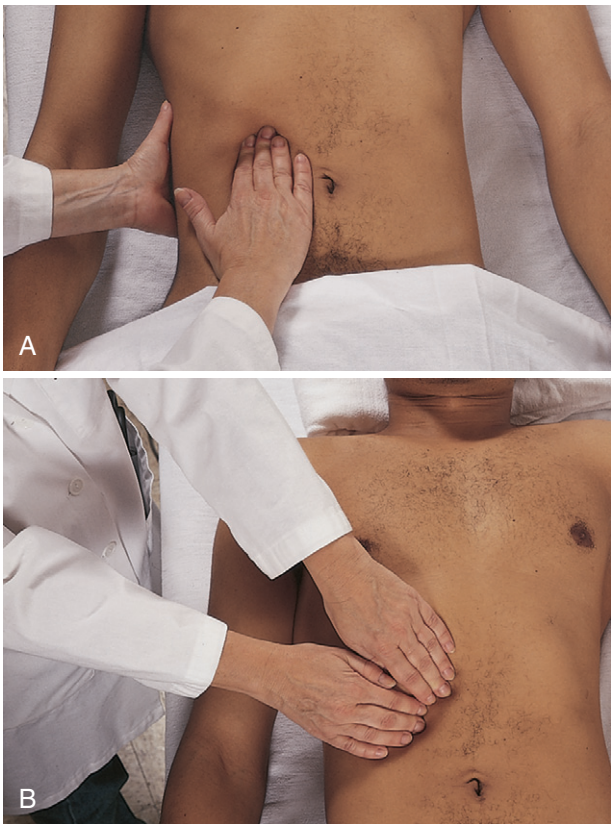

FIG. 39-8 A, Technique for liver palpation. **B,** Alternative technique to palpate liver with fingers hooked over the costal region. From Jarvis C: *Physical examination and health assessment,* ed 6, St Louis, 2012, Saunders.

To percuss the liver, start below the umbilicus in the right midclavicular line and percuss lightly upward until dullness is heard, thus determining the lower border of the liver. Next, start at the nipple line in the right midclavicular line and percuss downward between ribs to the area of dullness indicating the upper border of the liver. Measure the height or vertical space between the two borders to determine the size of the liver. The normal range of liver height in the right midclavicular line is 2.4 to 5 in (6 to 12.7 cm).

Palpation. *Light palpation* is used to detect tenderness or cutaneous hypersensitivity, muscular resistance, masses, and swelling. Help the patient relax for deeper palpation. Keep your fingers together and press gently with the pads of the fingertips, depressing the abdominal wall about 0.4 in (1 cm). Use smooth movements and palpate all quadrants (Fig. 39-7, *A*).

Deep palpation is used to delineate abdominal organs and masses (Fig. 39-7, *B*). Use the palmar surfaces of your fingers to press more deeply. Again, palpate all quadrants and note the location, size, and shape of masses, as well as the presence of tenderness. During these maneuvers, observe the patient's facial expression because it will provide nonverbal cues of discomfort or pain.

An alternative method for deep abdominal palpation is the two-hand method. Place one hand on top of the other and apply pressure to the bottom hand with the fingers of the top hand. With the fingers of the bottom hand, feel for organs and masses. Practice both methods of palpation to determine which one is most effective.

Check a problem area on the abdomen for rebound tenderness by pressing in slowly and firmly over the painful site. Withdraw the palpating fingers quickly. Pain on withdrawal of the fingers indicates peritoneal inflammation. Because assessing for rebound tenderness may produce pain and severe muscle spasm, it should be done at the end of the examination and only by an experienced practitioner.

To palpate the liver, place your left hand behind the patient to support the right eleventh and twelfth ribs (Fig. 39-8). The patient may relax on your hand. Press the left hand forward and place the right hand on the patient's right abdomen lateral to the rectus muscle. The fingertips should be below the lower border of liver dullness and pointed toward the right costal margin. Gently press in and up. The patient should take a deep breath with the abdomen so that the liver drops and is in a better position to be palpated. Try to feel the liver edge as it comes down to the fingertips. During inspiration the liver edge should feel firm, sharp, and smooth. Describe the surface and contour and any tenderness.

To palpate the spleen, move to the patient's left side. Place your right hand under the patient, and support and press the patient's left lower rib cage forward. Place your left hand below the left costal margin, and press it in toward the spleen. Ask the patient to breathe deeply. The tip or edge of an enlarged spleen will be felt by the fingertips. The spleen is normally not palpable. If it is palpable, do not continue because manual compression of an enlarged spleen may cause it to rupture.

TABLE 39-10 NORMAL PHYSICAL ASSESSMENT OF GASTROINTESTINAL SYSTEM

Mouth
- Moist and pink lips
- Pink and moist buccal mucosa and gingivae without plaques or lesions
- Teeth in good repair
- Protrusion of tongue in midline without deviation or fasciculations
- Pink uvula (in midline), soft palate, tonsils, and posterior pharynx
- Swallows smoothly without coughing or gagging

Abdomen
- Flat without masses or scars; no bruises
- Bowel sounds in all quadrants
- No abdominal tenderness; nonpalpable liver and spleen
- Liver 10 cm in right midclavicular line
- Generalized tympany

Anus
- Absence of lesions, fissures, and hemorrhoids
- Good sphincter tone
- Rectal walls smooth and soft
- No masses
- Stool soft, brown, and heme negative

CASE STUDY—cont'd

Objective Data: Physical Examination

iStockphoto/Thinkstock

A focused assessment of L.C. reveals the following: BP 120/74, heart rate 110, respiratory rate 24, temp 100.4° F (38° C). Abdomen firm and slightly distended. High-pitched bowel sounds in upper quadrants. No bowel sounds auscultated in left lower quadrant. Mild abdominal palpation elicits pain.

As you continue to read this chapter, consider diagnostic studies you would anticipate being performed for L.C.

The standard approach for examining the abdomen can be used on the older adult. Palpation is important because it may reveal a tumor. The abdomen may be thinner and more lax unless the patient is obese. If the patient has chronic obstructive pulmonary disease, large lungs, or a low diaphragm, the liver may be palpated 0.4 to 0.8 in (1 to 2 cm) below the right costal margin.

Rectum and Anus. Inspect perianal and anal areas for color, texture, masses, rashes, scars, erythema, fissures, and external hemorrhoids. Palpate any masses or unusual areas with a gloved hand.

For the digital examination of the rectum, place a gloved, lubricated index finger against the anus while the patient gently bears down (Valsalva maneuver). Then, as the sphincter relaxes, insert the finger. Point the finger toward the umbilicus. Try to get the patient to relax. Insert the finger into the rectum as far as possible, and palpate all surfaces. Assess any nodules, tenderness, or irregularities. A sample of stool can be removed with the gloved finger and checked for occult blood. However, a single guaiac-based fecal occult blood test has limited sensitivity in detecting colorectal cancer.

Findings of a normal physical assessment of the GI system are given in Table 39-10. Gerontologic differences in the GI system and differences in assessment findings are described in Table 39-5. Assessment abnormalities are presented in Table 39-11. A *focused assessment* is used to evaluate the status of previously identified GI problems and to monitor for signs of new problems (see Table 3-6). A focused assessment of the GI system is presented above.

FOCUSED ASSESSMENT

Gastrointestinal System

Use this checklist to make sure the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Loss of appetite	Y	N
Abdominal pain	Y	N
Changes in stools (e.g., color, blood, consistency, frequency)	Y	N
Nausea, vomiting	Y	N
Painful swallowing	Y	N

Objective: Diagnostic

Check the following laboratory results for critical values.

Endoscopy: colonoscopy, sigmoidoscopy, esophagogastroduodenoscopy	✓
CT scan	✓
Radiologic series: upper GI, lower GI	✓
Stool for occult blood or ova and parasites	✓
Liver function tests	✓

Objective: Physical Examination

Inspect

Skin for color, lesions, scars, petechiae, etc.	✓
Abdominal contour for symmetry and distention	✓
Perianal area for intact skin, hemorrhoids	✓

Auscultate*

Bowel sounds	✓

Palpate

Abdominal quadrants using light touch	✓
Abdominal quadrants using a deep technique	✓

*NOTE: Do auscultation before palpation.

DIAGNOSTIC STUDIES OF GASTROINTESTINAL SYSTEM

Table 39-12 presents common diagnostic studies of the GI system. Selected diagnostic studies are described in more detail below.

For most diagnostic studies, make sure a signed consent form for the procedure has been completed and is in the medical record. The health care provider doing the procedure is responsible for explaining the procedure and obtaining written consent. However, you play an important role in teaching patients about the procedures. When preparing the patient, it is important to ask about any known allergies to drugs, iodine, shellfish, or contrast media.

Many GI system diagnostic procedures require measures to cleanse the GI tract and the ingestion or injection of a contrast medium or a radiopaque tracer. Often the patient has a series of GI diagnostic tests done. Monitor the patient closely to ensure adequate hydration and nutrition during the testing period.

TABLE 39-11 ASSESSMENT ABNORMALITIES

Gastrointestinal System

Finding	Description	Possible Etiology and Significance
Mouth		
Ulcer, plaque on lips or in mouth	Sore or lesion	Carcinoma, viral infections
Cheilosis	Softening, fissuring, and cracking of lips at angles of mouth	Riboflavin deficiency
Cheilitis	Inflammation of lips (usually lower) with fissuring, scaling, crusting	Often unknown
Geographic tongue	Scattered red, smooth (loss of papillae) areas on dorsum of tongue	Unknown
Smooth tongue	Red, slick appearance	Cobalamin deficiency
Leukoplakia	Thickened white patches	Premalignant lesion
Pyorrhea	Recessed gingivae, purulent pockets	Periodontitis
Herpes simplex	Benign vesicular lesion	Herpesvirus
Candidiasis	White, curdlike lesions surrounded by erythematous mucosa	*Candida albicans*
Glossitis	Reddened, ulcerated, swollen tongue	Exposure to streptococci, irritation, injury, vitamin B deficiencies, anemia
Acute marginal gingivitis	Friable, edematous, painful, bleeding gingivae	Irritation from ill-fitting dentures or orthodontic appliances, calcium deposits on teeth, food impaction
Esophagus and Stomach		
Dysphagia	Difficulty swallowing, sensation of food sticking in esophagus	Esophageal problems, cancer of esophagus
Hematemesis	Vomiting of blood	Esophageal varices, bleeding peptic ulcer
Pyrosis	Heartburn, burning in epigastric or substernal area	Hiatal hernia, esophagitis, incompetent lower esophageal sphincter
Dyspepsia	Burning or indigestion	Peptic ulcer disease, gallbladder disease
Odynophagia	Painful swallowing	Cancer of esophagus, esophagitis
Eructation	Belching	Gallbladder disease
Nausea and vomiting	Feeling of impending vomiting, expulsion of gastric contents through mouth	GI infections, common manifestation of many GI diseases; stress, fear, and pathologic conditions
Abdomen		
Distention	Excessive gas accumulation, enlarged abdomen, generalized tympany	Obstruction, paralytic ileus
Ascites	Accumulated fluid within abdominal cavity, eversion of umbilicus (usually)	Peritoneal inflammation, heart failure, metastatic carcinoma, cirrhosis
Bruit	Humming or swishing sound heard through stethoscope over vessel	Partial arterial obstruction (narrowing of vessel), turbulent flow (aneurysm)
Hyperresonance	Loud, tinkling rushes	Intestinal obstruction
Borborygmi	Waves of loud, gurgling sounds	Hyperactive bowel as result of eating
Absent bowel sounds	No bowel sounds on auscultation	Peritonitis, paralytic ileus, obstruction
Absence of liver dullness	Tympany on percussion	Air from viscus (e.g., perforated ulcer)
Masses	Lump on palpation	Tumors, cysts
Rebound tenderness	Sudden pain when fingers withdrawn quickly	Peritoneal inflammation, appendicitis
Nodular liver	Enlarged, hard liver with irregular edge or surface	Cirrhosis, carcinoma
Hepatomegaly	Enlargement of liver, liver edge >1-2 cm below costal margin	Metastatic carcinoma, hepatitis, venous congestion
Splenomegaly	Enlarged spleen	Chronic leukemia, hemolytic states, portal hypertension, some infections
Hernia	Bulge or nodule in abdomen, usually appearing on straining	Inguinal (in inguinal canal), femoral (in femoral canal), umbilical (herniation of umbilicus), or incisional (defect in muscles after surgery)
Rectum and Anus		
Hemorrhoids	Thrombosed veins in rectum and anus (internal or external)	Portal hypertension, chronic constipation, prolonged sitting or standing, pregnancy
Mass	Firm, nodular edge	Tumor, carcinoma
Pilonidal cyst	Opening of sinus tract, cyst in midline just above coccyx	Probably congenital
Fissure	Ulceration in anal canal	Straining, irritation
Melena	Abnormal, black, tarry stool containing digested blood	Cancer, bleeding in upper GI tract from ulcers, varices
Tenesmus	Painful and ineffective straining at stool. Sense of incomplete evacuation	Inflammatory bowel disease, irritable bowel syndrome, diarrhea secondary to GI infection (e.g., food poisoning)
Steatorrhea	Fatty, frothy, foul-smelling stool	Chronic pancreatitis, biliary obstruction, malabsorption problems

FIG. 39-9 Barium enema x-ray showing the large intestine.

Some diagnostic studies are especially difficult and uncomfortable for the older adult. Adjustments may be needed during the preparation to avoid dehydration or worsening renal function, and during testing for positioning. Close monitoring is needed to avoid problems such as dehydration from prolonged fluid restriction and diarrhea from bowel-cleansing procedures.

Radiologic Studies

Upper Gastrointestinal Series. An upper GI series with small bowel follow-through provides visualization of the oropharyngeal area, the esophagus, the stomach, and the small intestine via fluoroscopy and x-ray examination. The procedure consists of the patient swallowing contrast medium (a thick barium solution or gastrografin) and then assuming different positions on the x-ray table. The movement of the contrast medium is observed with fluoroscopy, and several x-rays are taken (see Table 39-12). An upper GI series is used to identify disorders such as esophageal strictures, polyps, tumors, hiatal hernias, foreign bodies, and peptic ulcers.

Lower Gastrointestinal Series. The purpose of a lower GI series (barium enema) examination is to observe by means of fluoroscopy the colon filling with contrast medium and to

TABLE 39-12 DIAGNOSTIC STUDIES

Gastrointestinal System

Study	Description and Purpose	Nursing Responsibility
Radiology		
Upper gastrointestinal (GI) or barium swallow	Fluoroscopic x-ray study using contrast medium. Used to diagnose structural abnormalities of esophagus, stomach, and duodenum.	Explain procedure to patient, including the need to drink contrast medium and assume various positions on x-ray table. Keep patient NPO for 8-12 hr before procedure. Tell patient to avoid smoking after midnight before study. After x-ray, take measures to prevent contrast medium impaction (fluids, laxatives). Tell patient that stool may be white up to 72 hr after test.
Small bowel series	Contrast medium is ingested and films taken every 30 min until medium reaches terminal ileum.	Same as for upper GI.
Lower GI or barium enema	Fluoroscopic x-ray examination of colon using contrast medium, which is administered rectally (enema) (see Fig. 39-9). Double-contrast or air-contrast barium enema is test of choice. Air is infused after thick barium flows through transverse colon. Because of the use of endoscopy, not done as frequently.	*Before procedure:* Administer laxatives and enemas until colon is clear of stool evening before procedure. Administer clear liquid diet evening before procedure. Keep patient NPO for 8 hr before test. Instruct patient about being given barium by enema. Explain that cramping and urge to defecate may occur during procedure and that patient may be placed in various positions on tilt table. *After procedure:* Give fluids, laxatives, or suppositories to assist in expelling barium. Observe stool for passage of contrast medium.
Cholangiography		
• Percutaneous transhepatic (PTC)	After local anesthesia and monitored anesthesia care (formerly called conscious sedation), liver is entered with long needle (under fluoroscopy), bile duct is entered, bile withdrawn, and radiopaque contrast medium injected. Fluoroscopy is used to determine filling of hepatic and biliary ducts. IV antibiotics are given prophylactically.	Observe patient for signs of hemorrhage, bile leakage, and infection. Assess patient's medications for possible contraindications, precautions, or complications with use of contrast medium.
• Surgical cholangiogram	Performed during surgery on biliary structures, such as gallbladder. Contrast medium is injected into common bile duct.	Explain to patient that anesthetic will be used. Assess patient's medications for possible contraindications, precautions, or complications with use of contrast medium.
• Magnetic resonance cholangiopancreatography (MRCP)	Uses MRI technology to obtain images of biliary and pancreatic ducts.	Explain procedure to patient. Contraindicated in patient with metal implants (e.g., pacemaker) or one who is pregnant.

TABLE 39-12 DIAGNOSTIC STUDIES—cont'd

Gastrointestinal System

Study	Description and Purpose	Nursing Responsibility
Radiology—cont'd		
Ultrasound	Used to show the size and configuration of organ. Noninvasive procedure uses high-frequency sound waves (ultrasound waves), which are passed into body structures and recorded as they are reflected (bounded).	
• Abdominal ultrasound	Detects abdominal masses (tumors, cysts), biliary and liver disease, gallstones. A conductive gel (lubricant jelly) is applied to the skin and a transducer is placed on the area.	Instruct patient to be NPO 8-12 hr before ultrasound. Air or gas can reduce quality of images. Food intake can cause gallbladder contraction, resulting in suboptimal study.
• Endoscopic ultrasound (EUS)	Small ultrasound transducer is installed on tip of endoscope. Because EUS transducer gets close to the organ(s) being examined, images obtained are often more accurate and detailed than images provided by traditional ultrasound. Detects and stages esophageal, gastric, rectal, biliary, and pancreatic tumors and abnormalities. Fine-needle aspiration can be used to diagnose dysplasia or cancer.	Same as esophagogastroduodenoscopy (EGD).
• FibroScan or FibroTest	FibroScan (transient elastrography) uses an ultrasound transducer to determine liver stiffness (fibrosis). It is noninvasive and is used in patients with chronic hepatitis C and cirrhosis.	Patient lies in dorsal decubitus position with the right arm in extreme abduction. A probe is positioned in an intercostal space between the ribs.
Nuclear imaging scans (scintigraphy)	Shows size, shape, and position of organ. Functional disorders and structural defects may be identified. Radionuclide (radioactive isotope) is injected IV, and a counter (scanning) device picks up radioactive emission, which is recorded on paper. Only tracer doses of radioactive isotopes are used.	Tell patient that substance to be ingested contains only traces of radioactivity and poses little to no danger. Schedule no more than one radionuclide test on the same day. Explain to patient need to lie flat during scanning.
• Gastric emptying studies	Radionuclide study (scintigraphy) is used to assess ability of stomach to empty solids. Cooked egg containing Tc-99m and toast are eaten with water. Images are obtained at 0, 1, 2, and 4 hr later. Study is used in patients with gastric emptying disorders caused by peptic ulcer, ulcer surgery, diabetes, gastric malignancies, or functional disorders.	Same as above.
• Hepatobiliary scintigraphy (HIDA)	Patient is given IV injection of Tc-99m and positioned under camera to record distribution of tracer in liver, biliary tree, gallbladder, and proximal small intestine. Used to identify obstructions of bile ducts (e.g., gallstones, tumors), diseases of gallbladder, and bile leaks.	Same as above.
• Scintigraphy of GI bleeding	Tc-99m–labeled sulfur colloid or Tc-99m labeling of the patient's own red blood cells (RBCs) to determine the site of active GI blood loss. Sulfur colloid or the patient's RBCs are injected, and images of the abdomen are obtained at intermittent intervals.	Same as above.
Computed tomography (CT)	Noninvasive radiologic examination allows for exposures at different depths. Detects biliary tract, liver, and pancreatic disorders. Use of oral and IV contrast medium accentuates density differences.	Explain procedure to patient. Determine sensitivity to iodine or shellfish if contrast material used.
Magnetic resonance imaging (MRI)	Noninvasive procedure using radiofrequency waves and a magnetic field. Used to detect hepatobiliary disease, hepatic lesions, and sources of GI bleeding and to stage colorectal cancer. IV contrast medium (gadolinium) may be used.	Explain procedure to patient. Contraindicated in patient with metal implants (e.g., pacemaker) or one who is pregnant.
Virtual colonoscopy	Combines CT scanning or MRI with computer virtual reality software to detect intestine and colon diseases, including polyps, colorectal cancer, diverticulosis, and lower GI bleeding. Air is introduced via a tube placed in rectum to enlarge colon to enhance visualization. Images obtained while patient is on back and abdomen. Computer combines images to form 2- and 3-D pictures that are viewed on monitor.	Bowel preparation similar to colonoscopy (see Colonoscopy, below). Unlike conventional colonoscopy, no sedatives are needed and no scope is used. Procedure takes about 15-20 min.

TABLE 39-12 DIAGNOSTIC STUDIES—cont'd

Gastrointestinal System

Study	Description and Purpose	Nursing Responsibility
Endoscopy		
Esophagogastroduodenoscopy (EGD)	Directly visualizes mucosal lining of esophagus, stomach, and duodenum with flexible endoscope. Test may use video imaging to visualize stomach motility. Inflammations, ulcerations, tumors, varices, or Mallory-Weiss tears may be detected. Biopsies may be taken and varices can be treated with band ligation or sclerotherapy.	*Before procedure:* Keep patient NPO for 8 hr. Make sure signed consent is on chart. Give preoperative medication if ordered. Explain to patient that local anesthesia may be sprayed on throat before insertion of scope and that patient will be sedated during the procedure. *After procedure:* Keep patient NPO until gag reflex returns. Gently tickle back of throat to determine reflex. Use warm saline gargles for relief of sore throat. Check temperature q15-30min for 1-2 hr (sudden temperature spike is sign of perforation).
Colonoscopy	Directly visualizes entire colon up to ileocecal valve with flexible fiberoptic scope. Patient's position is changed frequently during procedure to assist with advancement of scope to cecum. Used to diagnose or detect inflammatory bowel disease, polyps, tumors, and diverticulosis and dilate strictures. Procedure allows for biopsy and removal of polyps without laparotomy.	*Before procedure:* Bowel preparation is done. This varies depending on physician. For example, patients may be kept on clear liquids 1-2 days before procedure. Cathartic and/or enema given the night before. An alternative is to give 1 gal of polyethylene glycol (GoLYTELY, Colyte) evening before (8-oz glass q10min) or Prepopik, one packet the night before colonoscopy and a second packet morning of colonoscopy. Explain to patient that flexible scope will be inserted while patient in side-lying position. Explain to patient that sedation will be given. *After procedure:* Patient may experience abdominal cramps caused by stimulation of peristalsis because the bowel is constantly inflated with air during procedure. Observe for rectal bleeding and manifestations of perforation (e.g., malaise, abdominal distention, tenesmus). Check vital signs.
Video capsule endoscopy (VCE)	Patient swallows a capsule with camera (approximately the size of a large vitamin), which provides endoscopic visualization of GI tract (see Fig. 39-11). Most commonly used to visualize small intestine and diagnose diseases such as Crohn's disease, small bowel tumors, small bowel injury due to NSAIDs, celiac disease, and malabsorption syndrome and to identify sources of possible GI bleeding in areas not accessible by upper endoscopy or colonoscopy. Camera takes >50,000 images during 8-hr examination. Capsule relays images to monitoring device that patient wears on belt. After examination, images are downloaded to a workstation. Not used in patients with suspected intestinal strictures.	Instruct patient to fast overnight. Patient may have bowel preparation similar to colonoscopy. The video capsule is swallowed, and clear liquids resumed after 2 hr and food and medications after 4 hr. Procedure is comfortable for most patients. Eight hours after swallowing the capsule, the patient returns to have the monitoring device removed. A patency capsule may be used first in patients determined to be high risk for capsule retention due to strictures. Peristalsis causes passage of the disposable capsule with a bowel movement.
Sigmoidoscopy	Directly visualizes rectum and sigmoid colon with lighted flexible endoscope. Sometimes special table is used to tilt patient into knee-chest position. Used to detect tumors, polyps, inflammatory and infectious diseases, fissures, hemorrhoids.	Administer enemas evening before and morning of procedure. Patient may have clear liquids day before, or no dietary restrictions may be necessary. Explain to patient knee-chest position (unless patient is older or very ill), need to take deep breaths during insertion of scope, and possible urge to defecate as scope is passed. Encourage patient to relax and let abdomen go limp. Observe for rectal bleeding after polypectomy or biopsy.
Endoscopic retrograde cholangiopancreatography (ERCP)	Fiberoptic endoscope (using fluoroscopy) is orally inserted into descending duodenum, then common bile and pancreatic ducts are cannulated. Contrast medium is injected into ducts and allows for direct visualization of structures. Technique can also be used to retrieve a gallstone from distal common bile duct, dilate strictures, biopsy, diagnose pseudocysts.	*Before procedure:* Explain procedure to patient, including patient role. Keep patient NPO 8 hr before procedure. Ensure consent form signed. Administer sedation immediately before and during procedure. Administer antibiotics if ordered. *After procedure:* Check vital signs. Check for signs of perforation or infection. Be aware that pancreatitis is most common complication. Check for return of gag reflex.
Endoscopic ultrasound	Combined use of endoscopy and ultrasound using an ultrasound transducer attached to an endoscope. Enables visualization of esophagus, stomach, intestine, liver, pancreas, and gallstones.	Similar to EGD.

Continued

TABLE 39-12 DIAGNOSTIC STUDIES—cont'd

Gastrointestinal System

Study	Description and Purpose	Nursing Responsibility
Endoscopy—cont'd		
Laparoscopy (peritoneoscopy)	Peritoneal cavity and contents are visualized with laparoscope. Biopsy specimen may also be taken. Done with patient in operating room. Double-puncture peritoneoscopy permits better visualization of abdominal cavity, especially liver. Can eliminate need for exploratory laparotomy in many patients.	Make sure signed consent is on chart. Keep patient NPO 8 hr before study. Administer preoperative sedative medication. Ensure that bladder and bowels are emptied. Observe for possible complications of bleeding and bowel perforation after the procedure.
Blood Studies		
Amylase	Measures secretion of amylase by pancreas. Is important in diagnosing acute pancreatitis. Level of amylase peaks in 24 hr and then drops to normal in 48-72 hr. Depending on method, *reference interval* is 30-122 U/L (0.51-2.07 μkat/L).	Obtain blood sample in acute attack of pancreatitis. Explain procedure to patient.
Lipase	Measures secretion of lipase by pancreas. Level stays elevated longer than serum amylase in acute pancreatitis. *Reference interval:* 31-186 U/L (0.5-3.2 μkat/L).	Explain procedure to patient.
Gastrin	Gastrin is a hormone secreted by cells of the antrum of the stomach, the duodenum, and the pancreatic islets of Langerhans. *Reference interval:* 25-100 pg/mL when fasting.	Explain procedure to patient.
Liver Biopsy	Percutaneous procedure uses needle inserted between 6th and 7th or 8th and 9th intercostal spaces on the right side to obtain specimen of hepatic tissue. Often done using ultrasound or CT guidance.	*Before procedure:* Check patient's coagulation status (prothrombin time, clotting or bleeding time). Ensure that patient's blood is typed and crossmatched. Take vital signs as baseline data. Explain holding of breath after expiration when needle is inserted. Ensure that informed consent has been signed. *After procedure:* Check vital signs to detect internal bleeding q15min × 2, q30min × 4, q1hr × 4. Keep patient lying on right side for minimum of 2 hr to splint puncture site. Keep patient in bed in flat position for 12-14 hr. Assess patient for complications such as bile peritonitis, shock, pneumothorax.
Fecal Tests		
Fecal analysis	Form, consistency, and color are noted. Specimen examined for mucus, blood, pus, parasites, and fat content. Tests for occult blood (guaiac test, Hemoccult, Hemoccult II, Hemoccult-SENSA, Hematest) are done. Single DNA test (PreGen-Plus) is a panel of DNA markers used to detect and monitor colorectal cancer.	Observe patient's stools. Collect stool specimens. Check stools for blood. Keep diet free of red meat for 24-48 hr before occult blood test.
Stool culture	Tests for the presence of bacteria, including *Clostridium difficile*.	Collect stool specimen.

observe by x-ray the filled colon. This procedure identifies polyps, tumors, and other lesions in the colon. It consists of administering an enema of contrast medium to the patient. The air-contrast barium enema provides better visualization (Fig. 39-9). Because it requires the patient to retain the barium, it is not tolerated as well in an older or immobile patient.

Virtual Colonoscopy. *Virtual colonoscopy* combines computed tomography (CT) scanning or magnetic resonance imaging (MRI) with computer software to produce images of the colon and the rectum. The test is less invasive than a conventional colonoscopy but does require radiation and prior cleansing of the colon (the technique is described in Table 39-12).

Virtual colonoscopy enables one to better see inside a colon that is narrowed due to inflammation or a growth.[11] However, if a polyp is discovered using virtual colonoscopy, a conventional colonoscopy will then be needed to obtain a biopsy or remove it. A disadvantage of virtual colonoscopy is that it may be less sensitive in obtaining information on the details and color of the mucosa. In addition, it is less sensitive in detecting small (less than 10 mm) or flat polyps.

Endoscopy

Endoscopy refers to the direct visualization of a body structure through a lighted fiberoptic instrument. The GI structures that can be examined by endoscopy include the esophagus, the stomach, the duodenum, and the colon. The pancreatic, hepatic, and common bile ducts can be visualized with an endoscope. This procedure is called *endoscopic retrograde cholangiopancreatography* (ERCP).

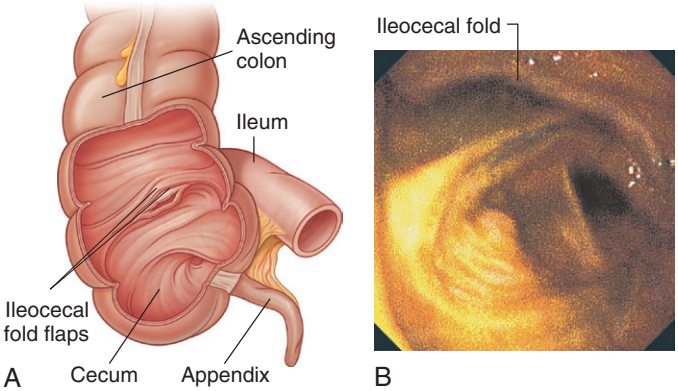

FIG. 39-10 **A,** Illustration showing the ileocecal junction and the ileocecal fold. **B,** Endoscopic image of the ileocecal fold.

CASE STUDY—cont'd

Objective Data: Diagnostic Studies

iStockphoto/Thinkstock

The ED physician performs a rectal examination and finds a palpable mass. The following diagnostic tests are ordered:

- CBC
- Electrolytes
- Liver function tests
- Urinalysis
- CT scan of the abdomen
- Colonoscopy

The CBC reveals an Hgb of 6.8 g/dL and an Hct of 20%. The white blood cell count is normal. The electrolytes, liver function tests, and urinalysis are within normal limits. The CT scan reveals pockets of gas and fluid in the ascending colon and two medium-sized tumors in the transverse colon.

This case study is continued in Chapter 43 on p. 1003.

The endoscope is an instrument through which biopsy forceps and cytology brushes may be passed. Cameras are attached, and video and still pictures can be taken (Fig. 39-10). Endoscopy is often done in combination with biopsy and cytologic studies.

The major complication of GI endoscopy is perforation through the structure being scoped. All endoscopic procedures require informed, written consent. Specific endoscopy procedures are discussed in Table 39-12. In addition to diagnostic procedures, many invasive and therapeutic procedures may be done with endoscopes. Examples include polypectomy, sclerosis or banding of varices, laser treatment, cauterization of bleeding sites, papillotomy, common bile duct stone removal, and balloon dilation. Many endoscopic procedures require IV short-acting sedation.

Capsule endoscopy is a noninvasive approach to visualize the GI tract (Fig. 39-11). (See Table 39-12 for further discussion of this diagnostic technique.) Its sensitivity in detecting the source of GI bleeding, small lesions, esophageal varices, colonic polyps, and colorectal cancer is under investigation.[12]

FIG. 39-11 Capsule endoscopy. **A,** The video capsule has its own camera and light source. After it is swallowed, it travels through the GI tract and allows visualization of the small intestine. It sends messages to a monitoring device that is worn on a waist belt **(B).** During the 8-hour examination, the patient is free to move about. After the test, the images are viewed on a video monitor.

Liver Biopsy

The purpose of a liver biopsy is to obtain hepatic tissue that can be used in establishing a diagnosis or assessing fibrosis. It may also be useful for following the progress of liver disease, such as chronic hepatitis.

The two types of liver biopsy are open and closed. The *open method* involves making an incision and removing a wedge of tissue. It is done in the operating room with the patient under general anesthesia, often concurrently with another surgical procedure. The *closed,* or *needle, biopsy* is a percutaneous procedure in which the site is infiltrated with a local anesthetic and a needle is inserted between the sixth and seventh or eighth and ninth intercostal spaces on the right side. The patient lies supine with the right arm over the head. Instruct the patient to expire fully and to not breathe while the needle is inserted (see Table 39-12).

Liver Function Studies

Liver function tests (LFTs) are laboratory (blood) studies that reflect hepatic disease. Table 39-13 describes some common LFTs.

TABLE 39-13 DIAGNOSTIC STUDIES

Liver Function Tests

Test	Description and Purpose
Bile Formation and Excretion	
Serum bilirubin	Measurement of liver's ability to conjugate and excrete bilirubin, allowing differentiation between unconjugated (indirect) and conjugated (direct) bilirubin in plasma.
• Total	Measurement of direct and indirect total bilirubin. *Reference interval:* 0.2-1.2 mg/dL (3-21 µmol/L)
• Direct	Measurement of conjugated bilirubin. Elevated in obstructive jaundice. *Reference interval:* 0.1-0.3 mg/dL (1.7-5.1 µmol/L)
• Indirect	Measurement of unconjugated bilirubin. Elevated in hepatocellular and hemolytic conditions. *Reference interval:* 0.1-1.0 mg/dL (1.7-17 µmol/L)
Urinary bilirubin	Measurement of urinary excretion of conjugated bilirubin. *Reference interval:* 0 or negative
Protein Metabolism	
Protein (serum)	Measurement of serum proteins manufactured by the liver. • Albumin, *reference interval:* 3.5-5.0 g/dL (35-50 g/L) • Globulin, *reference interval:* 2.0-3.5 g/dL (20-35 g/L) • Total protein, *reference interval:* 6.4-8.3 g/dL (64-83 g/L) • A/G ratio, *reference interval:* 1.5:1-2.5:1
α-Fetoprotein	Indication of hepatocellular cancer. *Reference interval:* <10 ng/mL (<10 mcg/L)
Ammonia	Conversion of ammonia to urea normally occurs in the liver. Increase can result in hepatic encephalopathy secondary to liver cirrhosis. *Reference interval:* 15-45 mcg N/dL (11-32 µmol N/L)

Test	Description and Purpose
Hemostatic Function	
Prothrombin time (PT)	Determination of prothrombin activity. *Reference interval:* 11-16 sec
International normalized ratio (INR)	Standardized system of reporting PT based on a reference calibration model and calculated by comparing the patient's PT with a control value. *Reference interval:* In general, 2-3 is the desired therapeutic level with warfarin (Coumadin), depending on laboratory
Vitamin K	Essential cofactor for many clotting factors. *Reference interval:* 0.1-2.2 ng/mL (0.22-4.88 nmol/L)
Serum Enzymes	
Alkaline phosphatase (ALP)	Originates from bone and liver. Serum levels rise when excretion is impaired as a result of obstruction in the biliary tract. *Reference interval:* 38-126 U/L (0.65-2.14 µkat/L), depending on method and age
Aspartate aminotransferase (AST)	Elevated in liver damage and inflammation. *Reference interval:* 10-30 U/L (0.17-0.51 µkat/L)
Alanine aminotransferase (ALT)	Elevated in liver damage and inflammation. *Reference interval:* 10-40 U/L (0.17-0.68 µkat/L)
γ-Glutamyl transpeptidase (GGT)	Present in biliary tract (not in skeletal or cardiac muscle). Increase in hepatitis and alcoholic liver disease. More sensitive for liver dysfunction than ALP. *Reference interval:* 0-30 U/L (0-0.5 µkat/L)
Lipid Metabolism	
Cholesterol (serum)	Synthesis and excretion by liver. Increase in biliary obstruction. Decrease in cirrhosis and malnutrition. *Reference interval:* <200 mg/dL (<5.2 mmol/L), varying with age

A/G, Albumin/globulin.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient is admitted to the hospital with a diagnosis of diarrhea with dehydration. The nurse recognizes that increased peristalsis resulting in diarrhea can be related to
   - **a.** sympathetic inhibition.
   - **b.** mixing and propulsion.
   - **c.** sympathetic stimulation.
   - **d.** parasympathetic stimulation.
2. A patient has an elevated blood level of indirect (unconjugated) bilirubin. One cause of this finding is that
   - **a.** the gallbladder is unable to contract to release stored bile.
   - **b.** bilirubin is not being conjugated and excreted into the bile by the liver.
   - **c.** the Kupffer cells in the liver are unable to remove bilirubin from the blood.
   - **d.** there is an obstruction in the biliary tract preventing flow of bile into the small intestine.
3. As gastric contents move into the small intestine, the bowel is normally protected from the acidity of gastric contents by the
   - **a.** inhibition of secretin release.
   - **b.** release of bicarbonate by the pancreas.
   - **c.** release of pancreatic digestive enzymes.
   - **d.** release of gastrin by the duodenal mucosa.
4. A patient is jaundiced and her stools are clay colored (gray). This is most likely related to
   - **a.** decreased bile flow into the intestine.
   - **b.** increased production of urobilinogen.
   - **c.** increased production of cholecystokinin.
   - **d.** increased bile and bilirubin in the blood.
5. An 80-year-old man states that, although he adds a lot of salt to his food, it still does not have much taste. The nurse's response is based on the knowledge that the older adult
   - **a.** should not experience changes in taste.
   - **b.** has a loss of taste buds, especially for sweet and salt.
   - **c.** has some loss of taste but no difficulty chewing food.
   - **d.** loses the sense of taste because the ability to smell is decreased.

6. When the nurse is assessing the health perception–health maintenance pattern as related to GI function, an appropriate question to ask is
   a. "What is your usual bowel elimination pattern?"
   b. "What percentage of your income is spent on food?"
   c. "Have you traveled to a foreign country in the last year?"
   d. "Do you have diarrhea when you are under a lot of stress?"
7. During an examination of the abdomen the nurse should
   a. position the patient in the supine position with the bed flat and knees straight.
   b. listen in the epigastrium and all four quadrants for 2 minutes for bowel sounds.
   c. use the following order of techniques: inspection, palpation, percussion, auscultation.
   d. describe bowel sounds as absent if no sound is heard in the lower right quadrant after 2 minutes.
8. A normal physical assessment finding of the GI system is/are *(select all that apply)*
   a. nonpalpable liver and spleen.
   b. borborygmi in upper right quadrant.
   c. tympany on percussion of the abdomen.
   d. liver edge 2 to 4 cm below the costal margin.
   e. finding of a firm, nodular edge on the rectal examination.
9. In preparing a patient for a colonoscopy, the nurse explains that
   a. a signed permit is not necessary.
   b. sedation may be used during the procedure.
   c. only one cleansing enema is necessary for preparation.
   d. a light meal should be eaten the day before the procedure.

1. d, 2. b, 3. b, 4. a, 5. b, 6. c, 7. b, 8. a, c, 9. b

LEARNING OUTCOMES

1. Relate the essential components of a well-balanced diet to their impact on health outcomes.
2. Describe the common etiologic factors, clinical manifestations, and management of malnutrition.
3. Describe the components of a nutritional assessment.
4. Explain the indications, complications, and nursing management principles related to the use of enteral nutrition.
5. Explain the indications, complications, and nursing management related to the use of parenteral nutrition.
6. Compare the etiologic factors, clinical manifestations, and nursing management of eating disorders.

bulimia nervosa, p. 903
enteral nutrition (EN), p. 897
malabsorption syndrome, p. 891
malnutrition, p. 890
parenteral nutrition (PN), p. 901
tube feeding, p. 897

This chapter focuses on problems related to nutrition. A review of normal nutrition provides a basis for evaluating nutritional status. Malnutrition and types of supplemental nutrition, including enteral and parenteral nutrition, are discussed. Obesity is discussed in Chapter 41.

NUTRITIONAL PROBLEMS

Nutrition is the sum of processes by which one takes in and utilizes nutrients.[1] Nutritional status can be viewed as a continuum from undernutrition to normal nutrition to overnutrition. An alteration in the process of nutrient intake or utilization can potentially cause nutritional problems. Nutritional problems occur in all age-groups, cultures, ethnic groups, and socioeconomic classes and across all educational levels.

The nutritional status of a person or a family is influenced by many factors. Attitudes toward the importance of food and eating habits are established early. Cultural or religious preferences and requirements are frequently reflected in dietary intake. The financial status of a family or an individual may influence the type and amount of nutritionally sound food that can be purchased.[2]

Reviewed by Katie Clark, RD, MPH CDE, Assistant Clinical Professor, Nutrition, University of California San Francisco, School of Nursing, San Diego, California; Shellie Simons, RN, PhD, Assistant Professor, University of Massachusetts Lowell, Lowell, Massachusetts; and Patricia Worthington, RN, MSN, CNSC, Nutritional Support Clinical Specialist, Thomas Jefferson University Hospital, Philadelphia, Pennsylvania.

NORMAL NUTRITION

Nutrition is important for energy, growth, and maintenance and repair of body tissues. Optimal nutrition (in the absence of any underlying disease process) results from the ingestion of a balanced diet. The major components of the basic food groups are carbohydrates, fats, proteins, vitamins, minerals, and water. Optimal nutrition and daily physical activity are essential for a healthy lifestyle.

The MyPlate approach to nutritional education *(www.choosemyplate.gov)* provides a visual guideline for sensible meal planning to help Americans eat healthfully and make good food choices. MyPlate focuses on the proportions of five food groups (grains, protein, fruits, vegetables, and dairy) that you should eat at each meal (Fig. 40-1, Table 40-1). eTables 40-1 and 40-2 (available on the website for this chapter) show the recommended daily amount of food from each food group and sample meal plans.

MyPlate materials have been developed for older adults and are available at *www.nutrition.tufts.edu/research/myplate-older-adults*. Tips on how to be physically active are available at *www.choosemyplate.gov/physical-activity.html*.

A growing number of electronic and print sources are available for determining nutritional information in commonly consumed foods. Nutrition Facts labels are listed on food products (Fig. 40-2). Calories, nutrients, and ingredients of food consumed can be easily tracked for healthy weight management. Consumer and health professional educational materials on the Nutrition Facts labels are available on the U.S. Food and Drug Administration (FDA) website.[3]

A person's daily caloric requirements are influenced by body type, age, gender, medications, physical activity, and the presence or absence of disease. Adjustments in caloric intake are necessary depending on changes in health status and daily activity level. The Mifflin–St. Jeor equation is recommended to estimate daily adult energy (calorie) requirements based on resting metabolic rate for individuals[4,5] (Table 40-2).

A more convenient way to estimate daily calories is based on kilocalories per kilogram (kcal/kg). (Kilocalorie [kcal] is the correct unit to designate caloric intake and expenditure. However, calorie is more commonly used.) An average adult requires an estimated 20 to 35 cal/kg of body weight per day, using an appropriate reference weight.[6] During illness, energy

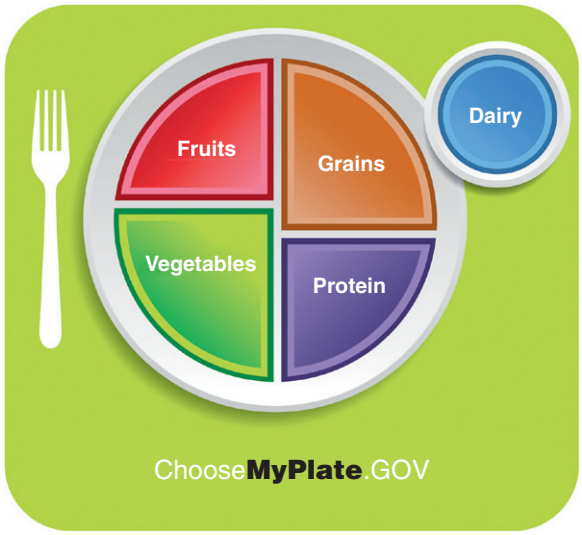

FIG. 40-1 MyPlate is the primary food group symbol that serves as a reminder to make healthy food choices and to build a healthy plate at mealtimes. It is a visual cue that identifies the five basic food groups from which to select healthy foods. The plate is divided into four slightly different-sized quadrants, with fruits and vegetables taking up half the space and grains and protein making up the other half. The vegetables and grains portions are the largest of the four. Next to the plate is a blue circle for dairy, which could be a glass of milk or a food such as cheese or yogurt. For more information, see *www.choosemyplate.gov*.

TABLE 40-1 NUTRITIONAL THERAPY

MyPlate Tips for a Healthy Lifestyle

Making food choices for a healthy lifestyle can be as simple as using these 10 tips. Use the ideas in this list to (1) balance your calories, (2) choose foods to eat more often, and (3) cut back on foods to eat less often.

1. Balance calories	Find out how many calories you need for a day as a first step in managing your weight. Go to *www.choosemyplate.gov* to find your calorie level. Being physically active also helps you balance calories.
2. Enjoy your food, but eat less	Take the time to fully enjoy your food as you eat it. Eating too fast or when your attention is elsewhere may lead to eating too many calories. Pay attention to hunger and fullness cues before, during, and after meals. Use them to recognize when to eat and when you have had enough.
3. Avoid oversized portions	Use a smaller plate, bowl, and glass. Portion out foods before you eat. When eating out, choose a smaller size option, share a dish, or take home part of your meal.
4. Foods to eat more often	Eat more vegetables, fruits, whole grains, and fat-free or 1% milk and dairy products. These foods have the nutrients you need for health, including potassium, calcium, vitamin D, and fiber. Make them the basis for meals and snacks.
5. Make half your plate fruits and vegetables	Choose red, orange, and dark-green vegetables like tomatoes, sweet potatoes, and broccoli, along with other vegetables, for your meals. Add fruit to meals as part of main or side dishes or as dessert.
6. Switch to fat-free or low-fat (1%) milk	They have the same amount of calcium and other essential nutrients as whole milk, but fewer calories and less saturated fat.
7. Make half your grains whole grains	To eat more whole grains, substitute a whole-grain product for a refined product. For example, eat whole-wheat bread instead of white bread, or brown rice instead of white rice.
8. Foods to eat less often	Cut back on foods high in solid fats, added sugars, and salt. They include cakes, cookies, ice cream, candies, sweetened drinks, pizza, and fatty meats like ribs, sausages, bacon, and hot dogs. Use these foods as occasional treats, not everyday foods.
9. Compare sodium in foods	Use the Nutrition Facts label (see Fig. 40-2) to choose lower sodium versions of foods like soup, bread, and frozen meals. Select foods labeled "low sodium," "reduced sodium," or "no salt added."
10. Drink water instead of sugary drinks	Cut calories by drinking water or unsweetened beverages. Soda, energy drinks, and sports drinks are a major source of added sugar and calories in American diets.

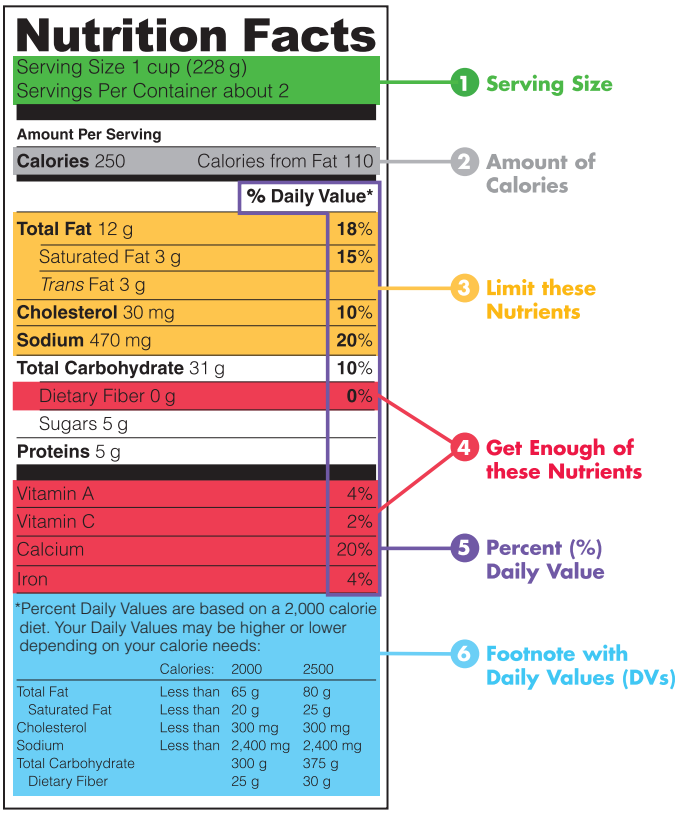
needs may be greater. Rule-of-thumb estimations are that an individual should consume 20 to 25 cal/kg body weight to lose weight, 25 to 30 cal/kg to maintain body weight, and 30 to 35 cal/kg to gain weight.

Carbohydrates, the body's primary source of energy, yield approximately 4 cal/g. Carbohydrates can be classified as either simple or complex. Simple carbohydrates come in two forms: monosaccharides (e.g., glucose, fructose), which are found in fruits and honey; and disaccharides (e.g., sucrose, maltose, lactose), which are found in foods such as table sugar, malted cereal, and milk, respectively. Complex carbohydrates or polysaccharides include starches, such as cereal grains, potatoes, and legumes.

Carbohydrates are the chief protein-sparing ingredient in a nutritionally sound diet. The Dietary Reference Intake (DRI) recommendations are that 45% to 65% of total calories should come from carbohydrates.[6] Furthermore, individuals should take approximately 14 g of dietary fiber per 1000 calories eaten per day from fruits, vegetables, and whole grains, equating to roughly 28 or 30 g for a typical 2000-calorie diet. Individuals should choose food and beverages with little added sugar or caloric sweeteners.



Fats are a major source of energy for the body. One gram of fat yields 9 calories. Fats are stored in adipose tissue and in the abdominal cavity. Fats also act as carriers of essential fatty acids and fat-soluble vitamins. Fats provide a feeling of satiety after eating. Individuals should limit their fat intake to 20% to 35% of total calories.[7]

Fats in the diet can be divided into (1) potentially harmful (saturated fat and *trans* fat) and (2) healthier dietary fat (monounsaturated and polyunsaturated fat) (see Fig. 34-3). One type of polyunsaturated fat, omega-3 fatty acids, may be especially beneficial to your heart. Omega-3 fatty acids, found in some types of fatty fish, appear to decrease the risk of coronary artery disease.[8]

Diets high in excess calories, usually in the form of fats, contribute to the development of obesity. Individuals should consume less than 10% of calories from saturated fatty acids (approximately 20 g of saturated fat per day in a 2000-calorie diet), limit intake of fat and oils high in *trans*-fatty acids, and limit intake of dietary cholesterol to 300 mg/day.

Proteins, another essential component of a well-balanced diet, are obtained from both animal and plant sources. Ideally, 10% to 35% of daily caloric needs should come from protein.[7] The recommended daily protein intake is 0.8 to 1 g/kg of body weight. One gram of protein yields 4 calories. Amino acids are the fundamental units of protein structure. The 22 amino acids are classified as essential and nonessential. The body is capable of synthesizing nonessential amino acids if an adequate supply of protein is available. However, the nine essential amino acids cannot be synthesized, and their availability depends totally on dietary sources. Protein sources containing all the essential amino acids are called *complete proteins.* Proteins that lack one or more of the essential amino acids are called *incomplete proteins.* Table 40-3 lists good sources of protein. Proteins are essential for tissue growth, repair, and maintenance; body regulatory functions; and energy production.

Vitamins are organic compounds required in small amounts for normal metabolism. Vitamins function primarily in enzyme

For educational purposes only. This label does not meet the labeling requirements described in 21 CFR 101.9.

FIG. 40-2 Sample of a Nutrition Facts label.

TABLE 40-2 ESTIMATING DAILY ENERGY (CALORIE) REQUIREMENTS

Mifflin–St. Jeor Equation

Men: Energy expenditure = 5 + 10 (wt in kg) + 6.25 (ht in cm) – 5 (age)
Women: Energy expenditure = –161 + 10 (wt in kg) + 6.25 (ht in cm) – 5 (age)
To determine total daily calorie needs, the energy expenditure has to be multiplied by the appropriate activity factor, as follows:
1.200 = sedentary (little or no exercise)
1.375 = lightly active (light exercise/sports 1-3 days/wk)
1.550 = moderately active (moderate exercise/sports 3-5 days/wk)
1.725 = very active (hard exercise/sports 6-7 days a wk)
1.900 = extra active (very hard exercise/sports and physical job)

Example

Man: Weight 180 lb, height 5 ft, 10 in, age 50, very active
Energy expenditure = 5 + 10 (82) + 6.25 (178) – 5 (50) × 1.725 = 2911
Woman: Weight 150 lb, height 5 ft,' 6 in", age 60, lightly active
Energy expenditure = –161 + 10 (68) + 6.25 (168) – 5 (60) × 1.375 = 1745

Ht, Height; *wt,* weight.

TABLE 40-3 GOOD SOURCES OF PROTEIN

Complete Proteins	Incomplete Proteins
• Milk and milk products (e.g., cheese)	• Grains (e.g., corn)
• Eggs	• Legumes (e.g., navy beans, soybeans, peas)
• Fish	• Nuts (e.g., peanuts)
• Meats	• Seeds (e.g., sesame seeds, sunflower seeds)
• Poultry	

TABLE 40-4 MAJOR MINERALS AND TRACE ELEMENTS

Major Minerals	Trace Elements
• Calcium	• Chromium
• Chloride	• Copper
• Magnesium	• Fluoride
• Phosphorus	• Iodine
• Potassium	• Iron
• Sodium	• Manganese
• Sulfur	• Molybdenum
	• Selenium
	• Zinc

reactions that facilitate the metabolism of amino acids, fats, and carbohydrates. Vitamins are divided into two categories: *water-soluble* vitamins (vitamin C and the B-complex vitamins) and *fat-soluble* vitamins (vitamins A, D, E, and K). Because the body stores excess fat-soluble vitamins, there is the potential for toxicity when too much is consumed. Upper limits have been established for vitamins A, D, and E.

Mineral salts (e.g., magnesium, iron, calcium) make up approximately 4% of the total body weight. Minerals present in minute amounts are referred to as *trace elements.* Minerals required in amounts greater than 100 mg/day are called *major minerals*. Table 40-4 lists the major minerals and trace elements. Minerals are necessary for the body to build and repair tissues, regulate body fluids, and assist in various functions. Some minerals are stored and can be toxic if taken in excess amounts. The amount of minerals needed in the daily diet varies greatly, from a few micrograms of trace minerals to 1 g or more of the major minerals, such as calcium, phosphorus, and sodium. A well-balanced diet can usually meet the daily requirements of minerals. However, deficiency and excess states can occur.

SPECIAL DIET: VEGETARIAN DIET

The common element among all vegetarians is the exclusion of red meat from the diet. There are many types of vegetarians and no strict definition of the word "vegetarian." Many vegetarians are *vegans,* who are pure or total vegetarians and eat only plants, and *lacto-ovo-vegetarians,* who eat plants and sometimes dairy products and eggs.

Vegetarians can have vitamin or protein deficiencies unless their diets are well planned. Plant protein, although of a lesser quality than that of animal origin, fulfills most of the protein requirements. Combinations of vegetable protein foods (e.g., cornmeal, kidney beans) can increase the nutritional value. Milk made from soybeans or almonds is also an excellent protein source and should be calcium fortified. Other deficiencies that may be present in a vegan diet include calcium, zinc, and vitamins A and D.

The primary deficiency for a strict vegan is lack of cobalamin. This vitamin can be obtained only from animal protein, special supplements, or foods that have been fortified with the vitamin. Vegans not using cobalamin supplements are susceptible to the development of megaloblastic anemia and the neurologic signs of cobalamin deficiency.

Strict vegetarians and lacto-ovo-vegetarians are also at risk for iron deficiency. Table 40-5 lists examples of foods high in iron.

TABLE 40-5 NUTRITIONAL THERAPY

Foods High in Iron*

Food	Selected Serving Size
Breads, Cereals, and Grain Products	
Farina, regular or quick cooked (enriched)	⅔ cup
Oatmeal, instant, fortified, prepared (enriched)	⅔ cup
Ready-to-eat cereals, fortified (enriched)	1 oz
Meat, Poultry, Fish, and Alternatives	
Beef liver, braised	3 oz
Pork liver, braised	3 oz
Chicken or turkey liver, braised	½ cup diced
Clams: steamed, boiled, or canned (drained)	3 oz
Oysters: baked, broiled, steamed, or canned (undrained)	3 oz
Soybeans, cooked	½ cup

*These foods provide 25%-39% of the Dietary Reference Intake (DRI) of iron.

CULTURALLY COMPETENT CARE

NUTRITION

People have unique cultural heritages that may affect eating customs and nutritional status. Each culture has its own beliefs and behaviors related to food and the role that food plays in the etiology and treatment of disease. In addition, culture and religion can influence what food is considered edible, how it is prepared, when it is eaten, and how and who prepares it. For example, some religions, such as Judaism and Islam, have specific laws regarding food. (The websites for Kosher Quest *[www.kosherquest.org]* and the Islamic Food and Nutrition Council of America *[www.ifanca.org]* provide detailed information.) Assess the extent to which Jewish or Muslim patients adhere to Kosher or Halal dietary practices to ensure that appropriate meals are served.

Assess the patient's diet history and implement necessary dietary changes. Avoid *cultural stereotyping* by making assumptions or generalizations about diet based on an individual's cultural background. Dietary habits differ considerably within and among ethnic groups. Acculturation, the extent to which immigrants adopt attributes of a new culture, can also affect dietary practices.[9]

It is important to know whether the patient eats "traditional foods" associated with the culture. If traditional foods are eaten, assess their impact on health. For example, "soul foods," which include traditional foods eaten by some African Americans, tend to be high in fat, cholesterol, and sodium.[10] Traditional foods eaten by some Asian Americans may be high in fiber and low in fat and cholesterol, but the diet may also be low in calcium because of limited dairy product intake.[11]

Consideration of cultural beliefs is important when planning and monitoring acceptance of dietary changes. Perception of body weight and size may also be influenced by culture. Ask the patient or family about how culture affects dietary choices and weight maintenance. For example, in some cultures overweight and obesity do not carry the stigma that they do in Western cultures.[12] This may make teaching regarding the necessity of weight reduction more challenging. A Jewish patient who eats only Kosher food may be comforted in knowing that most enteral formulas are manufactured Kosher and are labeled as such. Another example of culturally sensitive planning is

adjusting meal service plans for the Muslim patient observing Ramadan (the Islamic month of *fasting,* in which Muslims refrain from eating and drinking during daylight hours).

Teaching related to dietary restrictions and recommended dietary changes should involve the patient's family. Often it is a family member who does the grocery shopping and cooking.

MALNUTRITION

Malnutrition is a deficit, excess, or imbalance of essential nutrients. It may occur with or without inflammation. Malnutrition affects body composition and functional status.[13] Imbalances in macronutrients (carbohydrates, proteins, fat) or micronutrients (electrolytes, minerals, vitamins) occur with malnutrition. Terms such as *undernutrition* and *overnutrition* are also used to describe malnutrition.

Undernutrition describes a state of poor nourishment as a result of inadequate diet or diseases that interfere with normal appetite and assimilation of ingested food. *Overnutrition* refers to the ingestion of more food than is required for body needs, as in obesity.

Malnutrition is a problem in both developing and developed countries across the care continuum (community, hospital, long-term care).[13] Twenty percent to 70% of hospitalized adults are considered malnourished or at nutritional risk.[14] The prevalence of malnutrition in older adults based on the Mini Nutritional Assessment (MNA) ranges from approximately 6% (community-dwelling older adults) to 50% (rehabilitation settings).[15]

Etiology of Malnutrition

Many terms are used to describe the types and etiologies of adult malnutrition.[16,17] Older terms that are still used in some settings include *primary* or *secondary protein-calorie malnutrition* (PCM), *marasmus,* and *kwashiorkor.* Marasmus and kwashiorkor describe forms of malnutrition seen in children in developing countries;[17] these terms should not be used to describe malnutrition in adults.

The following etiology-based terminology is the preferred terminology to use in clinical practice settings, since it indicates the interaction and importance of inflammation on nutritional status.[16,18]

- *Starvation-related malnutrition,* or primary PCM, occurs when nutritional needs are not met (Fig. 40-3). It is a clinical state in which there is chronic starvation without inflammation (e.g., anorexia nervosa).
- *Chronic disease–related malnutrition,* or secondary PCM, is associated with conditions that impose sustained inflammation of a mild to moderate degree.[16] This occurs when tissue needs are not met even though the dietary intake would be satisfactory under normal conditions. Examples of conditions associated with this type of malnutrition include organ failure, cancer, rheumatoid arthritis, obesity, and metabolic syndrome.
- *Acute disease– or injury-related malnutrition* is associated with acute disease or injury states with marked inflammatory response (e.g., major infection, burns, trauma, closed head injury).

FIG. 40-3 Patient with malnutrition.

Contributing Factors to Malnutrition

Many factors contribute to the development of malnutrition, including socioeconomic factors, physical illnesses, incomplete diets, and food-drug interactions. Table 40-6 lists conditions that increase the risk for malnutrition.

Socioeconomic Factors. *Food security* refers to access by all people, at all times, to sufficient food for an active and healthy lifestyle.[2] Individuals or families with limited financial resources may have *food insecurity* (inadequate access). Food insecurity is problematic because it affects the overall quality of food that is available in both quantity and nutritional value. Families with food insecurity usually choose less expensive "filling" foods, which are more energy dense (high fat) and lack nutritional value. This type of diet increases the risk of nutrient deficiencies.

To help them obtain food, individuals and families may use "safety net programs," including food assistance programs; housing and energy subsidies; and in-kind contributions from relatives, friends, food pantries, or charitable organizations.

Consult with social workers to help patients gain access to government and local programs such as Meals on Wheels that deliver nutritious meals to home-bound individuals. The "heat or eat" phenomenon is problematic, as families with limited economic resources struggle to pay household utility bills or put food on the table. Older adults on a fixed income have an added burden of deciding on whether to pay for medications or food. You and the registered dietitian can assist patients in making food choices that meet nutritional requirements while staying within their limited resources.

Physical Illnesses. Malnutrition is a common consequence of illness, surgery, injury, or hospitalization. The hospitalized patient, especially the older adult, is at risk of becoming malnourished. Prolonged illness, major surgery, sepsis, draining wounds, burns, hemorrhage, fractures, and immobilization can

TABLE 40-6 CONDITIONS THAT INCREASE THE RISK FOR MALNUTRITION

- Dementia
- Depression
- Chronic alcoholism
- Excessive dieting to lose weight
- Swallowing disorders (e.g., head and neck cancer)
- Decreased mobility that limits access to food or its preparation
- Nutrient losses from malabsorption, dialysis, fistulas, or wounds
- Drugs with antinutrient or catabolic properties such as corticosteroids and oral antibiotics
- Extreme need for nutrients because of hypermetabolism or stresses such as infection, burns, trauma, or fever
- No oral intake and/or receiving standard IV solutions (5% dextrose) for 10 days (adults) or for 5 days (older adults)

all contribute to malnutrition. Pathologic conditions are frequently aggravated by undernutrition, and an existing deficiency state is likely to become more severe during illness.

Anorexia, nausea, vomiting, diarrhea, abdominal distention, and abdominal cramping may accompany diseases of the GI system. Any combination of these symptoms interferes with normal food consumption and metabolism. In addition, a patient may restrict dietary intake to a few foods or fluids that may not be nutritionally sound out of fear of aggravating an existing GI problem.

Malabsorption syndrome is the impaired absorption of nutrients from the GI tract. Decreases in digestive enzymes or in bowel surface area can quickly lead to a deficiency state. Many drugs have undesirable GI side effects and alter normal digestive and absorptive processes. For example, antibiotics change the normal flora of the intestines, decreasing the body's ability to synthesize biotin.

Fever accompanies many illnesses, injuries, and infections, with a concomitant increase in the body's basal metabolic rate (BMR). Each degree of temperature increase on the Fahrenheit scale raises the BMR by about 7%.[19] Without an increase in caloric intake, body protein stores will be used to supply calories, and protein depletion develops.

Assume responsibility, along with the health care provider and the registered dietitian, for meeting the patient's nutritional needs. Also consider the nutritional requirements of a patient who is not overtly ill but who is undergoing diagnostic studies. This patient may be nutritionally fit on entering the hospital but can develop nutritional problems because of the dietary restrictions imposed by multiple diagnostic studies.

Incomplete Diets. Vitamin deficiencies are rare in most developed countries, except for individuals with eating disorders and chronic abusers of alcohol. Vitamin deficiencies usually involve several vitamins, rather than a single one. The recommended dietary allowances, or DRIs, for essential vitamins and minerals (Table 40-7) can be obtained by eating a diet consisting of foods from the five basic food groups (see Fig. 40-1). DRIs from the Food and Nutrition Board have a safety margin because the levels exceed minimum daily requirements for most people.[20]

When vitamin imbalances do occur, they are usually found among persons with a pattern of alcohol and drug abuse, persons who are chronically ill, and individuals who follow poor dietary practices. Persons who have had surgery on the GI tract may be at risk for vitamin deficiencies. For example, resection of the terminal ileum poses a risk for deficiencies of fat-soluble vitamins. After a gastrectomy, patients require cobalamin supplementation because intrinsic factor (normally made in the stomach) is not available to bind with cobalamin so that this vitamin can be absorbed in the ileum. Followers of fad diets or poorly planned vegetarian diets are also at risk.

Clinical manifestations of vitamin imbalances are most commonly neurologic signs. The recommended DRIs and manifestations of imbalances are presented in eTable 40-3 (available on the website for this chapter).

Food-Drug Interactions. When the patient's health conditions require drug therapy, drug and food interactions may occur. Potential adverse interactions include incompatibilities, altered drug effectiveness, and impaired nutritional status. Food-drug interactions can also occur with the use of over-the-counter drugs and herbs and dietary supplements. Monitor and prevent these potential interactions for patients in the hospital and at home. Examples of common food-drug interactions are presented in eTable 40-4 (available on the website for this chapter). Additional information is available at *www.foodmedinteractions.com*.

TABLE 40-7 RECOMMENDED DAILY VITAMIN AND CALCIUM INTAKE*

Vitamin or Mineral	Dietary Reference Intake
Fat-Soluble Vitamins	
A	*Men:* 900 mcg/retinol equivalents *Women:* 700 mcg/retinol equivalents
D	*Adults ages 19-70:* 600 IU *Adults age >70:* 800 IU
E	*Adults:* 15 mg
K	*Men:* 120 mcg *Women:* 90 mcg
Water-Soluble Vitamins	
B_1	*Men:* 1.2 mg *Women:* 1.1 mg
B_6	*Men ages 19-50:* 1.3 mg *Men age >51:* 1.7 mg *Women ages 19-50:* 1.3 mg *Women age >51:* 1.5 mg
Cobalamin (B_{12})	*Adults:* 2-4 mcg
C	*Men:* 90 mg *Women:* 75 mg
Folate (folic acid)	*Adults:* 400 mcg
Minerals	
Calcium	*Men ages 19-70:* 1000 mg *Men age >70:* 1200 mg *Women ages 19-50:* 1000 mg *Women age >51:* 1500 mg

Pathophysiology of Starvation

Knowing the pathophysiology of the starvation process helps to understand the physiologic changes that occur in malnutrition. Initially, the body selectively uses carbohydrates (glycogen) rather than fat and protein to meet metabolic needs. These carbohydrate stores, found in the liver and the muscles, are minimal and may be totally depleted within 18 hours. During this early phase of starvation, protein is used only in its normal participation in cellular metabolism. However, once carbohydrate stores are depleted, skeletal protein is converted to glucose for energy. Alanine and glutamine are the first amino acids to be used by the liver for the formation of glucose in a process termed *gluconeogenesis*. The resulting available plasma glucose allows the metabolic processes to continue. With these amino acids being used as energy sources, the person may be in negative nitrogen balance (nitrogen excretion exceeds nitrogen intake). Within 5 to 9 days, body fat is fully mobilized to supply much of the needed energy.

In prolonged starvation, up to 97% of calories are provided by fat, and protein is conserved. Depletion of fat stores depends on the amount available, but fat stores are generally used up in

4 to 6 weeks. Once fat stores are used, body or visceral proteins, including those in internal organs and plasma, can no longer be spared and rapidly decrease because they are the only remaining body source of energy available.

If a malnourished patient has surgery, experiences physical trauma, or has an infection, the stress response is superimposed on the starvation response. Protein stores are used for body energy to meet the increased metabolic energy expenditure.

As the protein depletion continues, liver function becomes impaired, and synthesis of proteins decreases. The plasma oncotic pressure is lower because of decreased protein synthesis. A major function of plasma proteins, primarily albumin, is the maintenance of the osmotic pressure of the blood. Because of decreased oncotic pressure, body fluids shift from the vascular space into the interstitial compartment. Eventually albumin leaks into the interstitial space along with the fluid. Edema becomes clinically observable. Often the edema in the patient's face and legs masks the underlying muscle wasting.

As the total blood volume is reduced, the skin appears dry and wrinkled. As fluids shift to the interstitial space, ions also move. Sodium (a predominant extracellular ion) is found in increased amounts within the cell, and potassium (a predominant intracellular ion) and magnesium are shifted to the extracellular space. The sodium-potassium exchange pump has high energy needs, using 20% to 50% of all calories ingested. When the diet is extremely deficient in calories and essential proteins, the pump will fail, leaving sodium inside the cell (along with water), and the cell will expand.

The liver is the body organ that loses the most mass during protein deprivation. It gradually becomes infiltrated with fat secondary to decreased synthesis of lipoproteins. If dietary protein and other necessary constituents are not given, death will rapidly ensue.

Impact of Inflammation. Inflammation affects nutrient metabolism and is an important component of the nutritional status. During the starvation process, there is a decreased BMR, sparing of skeletal muscle, and decreased protein breakdown. However, in inflammatory states, there are alterations in the expression of proinflammatory (e.g., interleukin-6) and antiinflammatory cytokines (e.g., interleukin-10). These cytokine changes result in increased protein and skeletal muscle breakdown, increased BMR, increased glucose turnover, decreased negative acute phase protein (albumin, prealbumin) production, and increased positive acute phase protein (e.g., C-reactive protein [CRP]) production.[16]

Clinical Manifestations

The clinical manifestations of malnutrition range from mild to emaciation (Fig. 40-4) and death. The most obvious clinical signs on physical examination are apparent in the skin (dry and scaly skin, brittle nails, rashes, hair loss), mouth (crusting and ulceration, changes in tongue), muscles (decreased mass and weakness), and CNS (mental changes such as confusion, irritability). The speed at which the malnutrition develops depends on the quantity and quality of the protein intake, caloric value, illness, and the person's age.

Clinical manifestations of malnutrition are the result of numerous interactions at the cellular level. As protein intake is severely reduced, the muscles, which are the largest store of protein in the body, become wasted and flabby, leading to weakness and fatigability. Decreased protein is available for repair, and as a result, wound healing may be delayed. The person is more susceptible to infections. Both humoral and cell-mediated immunity are deficient in malnutrition. There is a decrease in leukocytes in the peripheral blood. Phagocytosis is altered because of the lack of energy necessary to drive the process. Many malnourished individuals are anemic, generally as a result of nutritional deficiencies in iron and folic acid, the necessary building blocks for red blood cells (RBCs). A detailed listing of the clinical manifestations of malnutrition is available in eTable 40-5 (available on the website for this chapter).

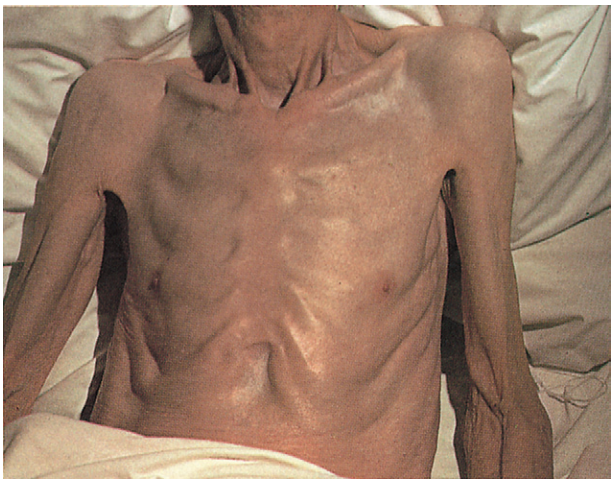

FIG. 40-4 Severe malnutrition that results in wasting and extensive loss of adipose tissue.

Diagnostic Studies

History and Physical Examination. A diet history of foods eaten over the past week reveals a great deal about the patient's dietary habits and knowledge of good nutrition. In addition to the height, weight, and vital signs, assess and document the patient's physical state and each body system. Table 40-8 summarizes the assessment and findings of the patient with malnutrition.

Laboratory Studies. The diagnosis of malnutrition is best determined by body composition, including a thorough history of weight loss, nutrient intake, and measures of functional status and inflammation. Serum albumin has a half-life of approximately 20 to 22 days. In the absence of marked fluid loss, such as from hemorrhage or burns, the serum albumin value lags behind actual protein changes by more than 2 weeks. Therefore albumin is not a good indicator of acute changes in nutritional status.

Prealbumin, a protein synthesized by the liver, has a half-life of 2 days and is a better indicator of recent or current nutritional status. Serum transferrin level is another indicator of protein status. Transferrin, a protein synthesized by the liver and used to transport iron, decreases when protein is deficient.

However, the extent to which visceral proteins, including albumin, prealbumin, and transferrin, are true markers of malnutrition is questionable. Albumin, prealbumin, and transferrin are *negative acute phase proteins,* which mean that during an inflammatory response, the synthesis of these proteins in the liver is decreased. Therefore low or below normal levels of these negative acute phase proteins correspond to an inflammatory state rather than accurately indicating nutritional status.[16,20]

CRP, which is a *positive acute phase protein,* is typically elevated during inflammation and predicts morbidity and mortal-

TABLE 40-8 NURSING ASSESSMENT

Malnutrition

Subjective Data

Important Health Information

Past health history: Severe burns, major trauma, hemorrhage, draining wounds, bone fractures with prolonged immobility, chronic renal or liver disease, cancer, malabsorption syndromes, GI obstruction, infectious diseases (TB, AIDS), acute (e.g., trauma, sepsis) or chronic inflammatory condition (e.g., rheumatoid arthritis)
Medications: Corticosteroids, chemotherapeutic agents, diet pills
Surgery or other treatments: Recent surgery, radiation

Functional Health Patterns

Health perception–health management: Alcohol or drug abuse; malaise, apathy
Nutritional-metabolic: Increase or decrease in weight, weight problems; increase or decrease in appetite, typical dietary intake; food preferences and aversions; food allergies or intolerance; ill-fitting or absent dentures; dry mouth, difficulty in chewing or swallowing; bloating or gas; ↑ sensitivity to cold; delayed wound healing
Elimination: Constipation, diarrhea, nocturia, decreased urine output
Activity-exercise: Increase or decrease in activity patterns; weakness, fatigue, decreased endurance
Cognitive-perceptual: Pain in mouth; paresthesias; loss of position and vibratory sense
Role-relationship: Change in family (e.g., loss of a spouse); financial resources
Sexual-reproductive: Amenorrhea, impotence, decreased libido

Objective Data

General

Listless, cachectic; underweight for height

Integumentary

Dry, brittle, sparse hair with color changes and lack of luster, alopecia; dry, scaly lips, fever blisters, angular crusts and lesions at corners of mouth (cheilosis); brittle, ridged nails; decreased tone and elasticity of skin; cool, rough, dry, scaly skin with brown-gray pigment changes; reddened, scaly dermatitis, scrotal dermatitis; slight cyanosis; peripheral edema

Eyes

Pale or red conjunctivae, gray keratinized epithelium on conjunctiva (Bitot's spots); dryness and dull appearance of conjunctivae and cornea, soft cornea; blood vessel growth in cornea; redness and fissuring of eyelid corners

Respiratory

Decreased respiratory rate, ↓ vital capacity, crackles, weak cough

Cardiovascular

Increased or decreased heart rate, ↓ BP, dysrhythmias

Gastrointestinal

Swollen, smooth, raw, beefy red tongue (glossitis), hypertrophic or atrophic papillae; dental cavities, absent or loose teeth, discolored tooth enamel; spongy, pale, receded gums with a tendency to bleed easily, periodontal disease; ulcerations, white patches or plaques, redness, swelling of oral mucosa; distended, tympanic abdomen; ascites, hepatomegaly, decreased bowel sounds; steatorrhea

Neurologic

Decreased or loss of reflexes, tremor; inattention, irritability, confusion, syncope

Musculoskeletal

Decreased muscle mass with poor tone, "wasted" appearance; bowlegs, knock-knees, beaded ribs, chest deformity, prominent bony structures

Possible Diagnostic Findings

↓ Hemoglobin and hematocrit; ↓ MCV, MCH, or MCHC (iron deficiency); ↓ MCV or MCH (folic acid or cobalamin deficiency); altered serum electrolyte levels, especially hyperkalemia; ↓ BUN and creatinine; ↓ serum albumin, transferrin, and prealbumin; ↓ lymphocytes; ↑ liver enzymes; ↓ serum vitamin levels

MCH, Mean corpuscular hemoglobin; *MCHC,* mean corpuscular hemoglobin concentration; *MCV,* mean corpuscular volume; *TB,* tuberculosis.

ity.[21,22] Serum electrolyte levels reflect changes taking place between the intracellular and extracellular spaces. The serum potassium level is often elevated. The RBC count and the hemoglobin level indicate the presence and degree of anemia. The total lymphocyte count decreases with malnutrition. It is calculated by multiplying the percent of lymphocytes times the total white blood cell (WBC) count. Liver enzyme levels, a reflection of liver function, may be elevated during malnutrition. Serum levels of both fat-soluble and water-soluble vitamins are usually decreased. The lowered serum levels of the fat-soluble vitamins correlate with the clinical signs of *steatorrhea* (fatty stools).

Anthropometric Measurements. Anthropometric measurements are gross measures of fat and muscle contents. These measurements tend to be most beneficial when done serially, and by well-trained anthropometrists, to evaluate the long-term effects of malnutrition or responses to nutritional interventions. They consist of measures of skinfold thickness at various sites, which are indicators of subcutaneous fat stores, and midarm muscle circumference, an indicator of protein stores. These measurements are then compared with standards for healthy persons of the same age and gender.

The sites most reflective of body fat are those over the biceps and the triceps, below the scapula, above the iliac crest, and over the upper thigh. Both skinfold thickness and midarm circumference measurements are decreased in malnutrition. These measurements may also be influenced by shifts in hydration status. The exact relationship of the midarm circumference measure to morbidity and mortality remains to be established.

Waist circumference and hip-to-waist ratio are used more commonly in acute care to reflect nutritional status. These measures are discussed in Chapter 41.

Functional Measurements. Measures of muscle strength are used to assess functional status, an important outcome of nutrition states. Handgrip strength is measured with a hand dynamometer. Functional performance tests such as the Short Physical Performance Battery may be ordered.[23]

NURSING AND COLLABORATIVE MANAGEMENT MALNUTRITION

NURSING ASSESSMENT

As a nurse, you are responsible for nutritional screening across care settings. Nutritional screening identifies individuals who are malnourished or at risk for malnutrition. Nutritional screening is also used to determine if a more detailed nutritional assessment is necessary. The Joint Commission requires

nutritional screening for all patients within 24 hours of admission. Many nutritional screening and assessment tools are available.[24,25] Hospital-specific screening tools based on common admission assessment criteria include history of weight loss, prior intake before admission, use of nutritional support, chewing or swallowing issues, and skin breakdown. A standardized approach to nutritional screening is needed to ensure valid and reliable tools are used in the clinical setting.

In older adults the Mini Nutritional Assessment (MNA) is often used[25] (available at *www.mna-elderly.com/forms/mini/mna_mini_english.pdf*). In long-term care the Minimum Data Set (MDS) form is used to obtain information about a person's nutritional status.[26] In home care settings the Outcome and Assessment Information Set (OASIS) prompts you to collect information on diet, oral intake, dental health, swallowing difficulties, and any need for meal assistance.[27]

If the nutritional screening identifies an individual at nutritional risk, a full nutritional assessment is most often needed. A nutritional assessment is a comprehensive approach that includes medical, nutritional, and medication histories; physical examination; anthropometric measurements; and laboratory data (Table 40-9). Nutritional assessment provides the basis for nutritional intervention.

Across all care settings, be aware of the patient's nutritional status. Obtaining an accurate measure of body weight and height and recording this information are critical components of this assessment. When assessing weight, obtain a detailed weight history, noting weight loss. Ask whether the weight loss was intentional or unintentional and the period over which it took place. A loss of more than 5% of usual body weight over 6 months, whether intentional or unintentional, is a critical indicator for further assessment, especially in the older adult.[28] If an involuntary weight loss exceeds 10% of the usual weight, determine the reason. Unintentional weight loss is also important to consider in the obese individual, since latent malnutrition may be present despite excess body weight. Determine the patient's current weight in relation to ideal body weight.

When possible, measure the patient's actual height rather than using the patient's self-report. Alternatives to standing height (stature) measurements include arm demi-span and knee-height measurements. The *arm demi-span* is the distance from a point on the midline at the suprasternal notch to the web between the middle and ring fingers with the arm horizontally outstretched *(www.mna-elderly.com/forms/mna_guide_english.pdf)*. For persons who are confined to bed, the use of a Luft ruler is an alternative to standing height.[29]

Body mass index (BMI) is a measure of weight for height (see Fig. 41-2). A BMI of less than 18.5 kg/m^2 is considered underweight, normal weight is a BMI between 18.5 and 24.9 kg/m^2, and overweight is a BMI between 25 and 29.9 kg/m^2. A BMI of 30 kg/m^2 or greater is obese. BMIs outside the normal weight range are associated with increased morbidity and mortality.[30]

In addition, obtain a complete diet history from the patient or caregiver. The patient's nutritional state may not be the reason medical care was sought. However, it may be a contributing factor to the disease and have an impact on management and recovery.

TABLE 40-9 COMPONENTS OF NUTRITIONAL ASSESSMENT

Anthropometric Measurements
- Height and weight
- Body mass index (BMI)
- Rate of weight change
- Amount of weight loss

Physical Examination
- Physical appearance
- Muscle mass and strength
- Dental and oral health

Health History
- Personal and family history
- Acute or chronic illnesses
- Current medications, herbs, supplements
- Cognitive status, depression

Diet History
- Chewing and swallowing ability
- Changes in appetite or taste
- Food and nutrient intake
- Availability of food

Laboratory Data
- Glucose
- Electrolytes
- Lipid profile
- Blood urea nitrogen (BUN)

Functional Status
- Ability to perform basic and instrumental activities of daily living
- Handgrip strength
- Performance tests (e.g., timed walk tests)

HEALTHY PEOPLE

Health Impact of a Well-Balanced Diet

- Reduces incidence of anemia
- Maintains normal body weight and prevents obesity
- Maintains good bone health and reduces risk of osteoporosis
- Lowers the risk of developing elevated cholesterol and type 2 diabetes mellitus
- Decreases the risk of heart disease, hypertension, and certain types of cancers

NURSING DIAGNOSES

Nursing diagnoses for the patient with malnutrition include, but are not limited to, the following:

- Imbalanced nutrition: less than body requirements *related to* decreased access, ingestion, digestion, or absorption of food or *related to* anorexia, dysphagia, or increased metabolic needs
- Feeding self-care deficit *related to* decreased strength and endurance, fatigue, and apathy
- Deficient fluid volume *related to* factors affecting access to or absorption of fluids
- Risk for impaired skin integrity *related to* poor nutritional state
- Noncompliance *related to* alteration in perception, lack of motivation, or incompatibility of regimen with lifestyle or resources

PLANNING

The overall goals are that the patient with malnutrition will (1) gain weight, particularly muscle mass; (2) consume a specified number of calories per day (with a diet individualized for the patient); and (3) have no adverse consequences related to malnutrition or nutritional therapies.

NURSING IMPLEMENTATION

HEALTH PROMOTION. You are in a good position to teach and reinforce healthy eating habits with individuals and groups of persons throughout their life span. Use MyPlate, Dietary Guidelines for Americans 2010, and Nutrition Facts food labels to promote healthy nutrition. Free interactive web-based programs are available to track physical activity, calories, and foods eaten (see *www.choosemyplate.gov*).

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

Does Nutritional Education Improve Functional Outcomes in Older Adults?

Clinical Question

In older adults (P) what is the effect of nutritional education (I) on diet, physical and emotional functioning, and quality of life (O)?

Best Available Evidence

- Systematic review of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- Twenty-three RCTs (n = 12,610) of community-dwelling older adults (65 yr and older) with various diseases. Five trials with nutritional education only; remaining trials with nutritional and lifestyle advice, exercise advice, or screening. Education varied in format and intensity.
- Outcomes included diet, functional outcomes (e.g., strength, balance), hospital readmissions, depression, anxiety, and quality of life.
- Results showed improved body mass index, weight loss, and physical health with decreased depression.
- Brief interventions were as effective as more lengthy ones.

Conclusion

- Nutritional education alone or in combination with other interventions positively influences physical and emotional health.

Implications for Nursing Practice

- Locate nutritional educational resources for older patients residing at home.
- Help patients identify community programs to make positive changes in lifestyle and exercise.

Reference for Evidence

P, Patient population of interest; *I*, intervention or area of interest; *O*, outcomes of interest (see p. 12).

ACUTE INTERVENTION. Assess the patient's nutritional state during your assessment of the patient's other physical problems. Identify nutritional risk factors and why they might exist. In states of increased stress, such as surgery, severe trauma, and sepsis, more calories and protein are needed. Wound healing requires increased protein synthesis. For patients undergoing major surgery or those with or at risk for malnutrition, several weeks of increased protein and calorie intake are needed preoperatively to promote healing postoperatively.

When fever is present, the metabolic rate is increased and nitrogen loss is accelerated. Despite the return of body temperature to normal, the rate of protein breakdown and resynthesis may be increased for several weeks. Teach the patient and caregiver the importance of good nutrition and the rationale for recording the daily weight, intake, and output. Daily weights can give an ongoing record of body weight gain or loss. However, rapid gains and losses are usually the result of shifts in fluid balance. The body weight, in conjunction with accurate recording of food and fluid intake, provides a clearer picture of the patient's fluid and nutritional state. To obtain an accurate weight, weigh the patient at the same time each day, on the same scale, with the same type or amount of clothing, and preferably with the bladder recently emptied.

TABLE 40-10 NUTRITIONAL THERAPY*

High-Calorie, High-Protein Diet

Suggestions for high-calorie, high-protein foods include the following.

Breads and Cereals
- Hot cereals (oatmeal, cream of wheat) prepared with milk, added fat (butter or margarine), and sugar
- Potatoes prepared with added fat (butter and whole milk)
- Granola and other cereals with dried fruit
- Croissants, buttermilk biscuits, muffins, banana bread, zucchini bread

Vegetables
- Vegetables prepared with added fat (margarine, butter)
- Fried vegetables

Fruits
- Canned fruit in heavy syrup
- Dried fruit

Meat
- Fried meats
- Meats covered in cream sauces or gravy
- Casseroles

Milk and Milk Products
- Milkshakes
- Whole milk and milk products (yogurt, ice cream, cheese)
- Whipping cream or heavy cream
- Whole milk with added nutritional supplements

*Suggested meal plans for high-calorie, high-protein diet are presented in eTable 40-6 (available on the website for this chapter).

The protein and calorie intake required in the malnourished patient depends on the cause of the malnutrition, the treatment being used, and other stressors affecting the patient. If the patient is able to take food by mouth, obtain a daily calorie count and diet diary to give an accurate record of food intake. You and the registered dietitian can assist the patient and family in selecting high-calorie and high-protein foods (unless medically contraindicated). Preparation of foods preferred by the patient enhances the daily intake. Encourage the family to bring the patient's favorite foods from home while the patient is hospitalized. Table 40-10 gives examples of high-calorie, high-protein foods.

The undernourished patient usually needs to have between-meal supplements. These may consist of items prepared in the dietary department or commercially prepared products. Eating these items between meals provides extra calories, proteins, fluids, and nutrients. If the patient is unable to consume enough nutrition with a high-calorie, high-protein diet, oral liquid nutritional supplements can be added.

Some patients may benefit from appetite stimulants such as megestrol acetate (Megace) or dronabinol (Marinol) to improve nutritional intake. If the patient is still unable to take in enough calories, enteral feedings may be considered. Parenteral nutrition (PN) might need to be initiated if enteral feedings are not feasible.[31] Contraindications for enteral nutrition include GI obstruction, prolonged ileus, severe diarrhea or vomiting, and enterocutaneous fistula.

AMBULATORY AND HOME CARE. With shortened hospital stays, many patients are discharged on a therapeutic diet. Discharge preparation for both the patient and the caregiver is essential. Teach them about the cause of the undernourished state and ways to avoid the problem in the future. Individuals need to be aware that undernourishment, whatever the cause, can recur and that adhering to a diet high in protein and calories for a few weeks cannot fully restore a normal nutritional state. Many months may be needed to reach this goal. Assess the patient's understanding and reinforce the information whenever possible. Assess the patient's and caregiver's ability to comply with

the dietary instructions in light of past eating habits, religious and ethnic preferences, age, income, other resources, and state of health. Emphasize the need for continual follow-up care if rehabilitation is to be accomplished and maintained. In the discharge planning, ensure proper follow-up such as visits by the home health nurse and outpatient registered dietitian referrals.

Determine the need for nutritious meals and snacks after discharge from the hospital. The ability of the patient or caregiver to access a registered dietitian may be limited. As a nurse, you may be the primary source of nutritional information. In your assessment, consider the availability and acceptability of community resources that provide meals such as Meals on Wheels, senior congregate feeding sites, and the Supplemental Nutrition Assistance Program (SNAP, formerly known as Food Stamps). Help the patient identify reliable Internet sources that provide evidence-based food and nutrition recommendations.

Keeping a diet diary for 3 days at a time is one way to analyze and reinforce healthful eating patterns. These records are also helpful to the health care team in the follow-up care. Encourage self-assessment of progress by having the patient weigh himself or herself once or twice a week and keep a weight record.

EVALUATION

The expected outcomes are that the patient who is malnourished will

- Achieve and maintain optimal body weight
- Consume a well-balanced diet
- Experience no adverse outcomes related to malnutrition
- Maintain optimal physical functioning

GERONTOLOGIC CONSIDERATIONS

MALNUTRITION

Older adults are particularly vulnerable to malnutrition across care settings.[32] Nutrition affects quality of life, functional status, and health in older adults. Older hospitalized adults with malnutrition are more likely to have poor wound healing, pressure ulcers, infections, decreased muscle strength, postoperative complications, and increased morbidity and mortality risks.[28] You play an important role in assessing the physiologic, functional, environmental, dietary, psychologic, and social factors related to nutritional risk in older adults. Older adults are also less able to regain body weight after periods of undernutrition due to illness or surgery.

Older adults may report little or no appetite, problems with eating or swallowing, inadequate servings of nutrients, and fewer than two meals per day. Limited incomes may cause them to restrict the number of meals or the dietary quality of meals eaten. Social isolation is a problem in older adults. Older adults who live alone may lose their desire to cook and report decreased appetite. Functional limitations may also affect the ability to feed one's self or to purchase food, cook, or prepare meals. Furthermore, older adults may lack transportation to buy food.

Chronic illnesses associated with aging can also affect nutritional status. For example, depression and dysphagia (secondary to stroke) can affect intake. Poor oral health from cavities, gum disease (gingivitis), and missing teeth, as well as *xerostomia* (dry mouth), can impair the older adult's ability to lubricate, masticate, and swallow food. Medications can cause dry mouth, alter the taste of food, or decrease appetite.

Physiologic changes associated with aging include a decrease in lean body mass and redistribution of fat around internal organs, which can lead to a decreased caloric requirement. Furthermore, changes in odor and taste perception (from medications, nutrient deficiencies, or taste-bud atrophy) can alter nutritional status. Sarcopenia is a loss of lean body mass with aging and affects muscle strength and function. Older adults on bed rest or prolonged inactivity lose more lean body mass than younger adults.[30]

Measure weight and height on admission, and routinely assess and document the person's weight. Determine if there is a history of voluntary or involuntary weight loss. Collaborate with the primary care provider and registered dietitian to identify the cause for weight loss and implement appropriate interventions.

Daily requirements for healthy older adults for weight maintenance include 30 cal/kg of body weight, and 0.8 to 1 g/kg of protein per day, with no more than 30% of calories from fat.[28,30] Nutritional requirements may differ depending on the degree of malnutrition and physiologic stress. To prevent loss of muscle mass and maintain function, some experts recommend older adults consume a moderate amount of high-quality protein at each meal.[33] Daily calcium and vitamin D requirements are higher for older adults (see Table 40-7).

Focus your initial care strategies on improving oral intake and providing a stimulating environment for meals. Special strategies, such as adaptive devices (e.g., large-handled eating utensils), often are helpful in increasing dietary intake.

Oral liquid supplements may have a role in improving the nutritional status of older adults.[34] Do not use supplements as meal substitutes, but use them between meals as snacks. In long-term care these beverages may be used instead of water with oral medication administration to increase caloric intake. Some older persons may require nutritional support therapies until their strength and general health improve. Before starting any nutritional support therapy (e.g., enteral or parenteral nutrition) for an older patient unable to give consent, review his or her advance directives regarding the use of artificial nutrition and hydration.

Malnourished or nutritionally at-risk older adults are vulnerable when discharged from the hospital to the home. Older adults may not be able to shop for or prepare foods during the initial recovery period.[35] Consult with the social worker and registered dietitian to ensure that older adults have access to food on discharge. Home-delivered meals or senior congregate feeding programs are an appropriate referral. Many community nutritional programs are available to the older person to make mealtime a pleasant, social event. Improving the social setting of a meal frequently improves dietary intake. The use of SNAP is another alternative that allows low-income households, regardless of age, to buy more food of a greater variety.

Older adults with dementia or a stroke present unique nursing challenges with regard to eating and feeding. (Dementia is discussed in Chapter 60, and strokes are discussed in Chapter 58.)

TYPES OF SPECIALIZED NUTRITIONAL SUPPORT

Oral Feeding

Oral supplements may be used in the patient whose nutritional intake is deficient. This may include milkshakes, puddings, or

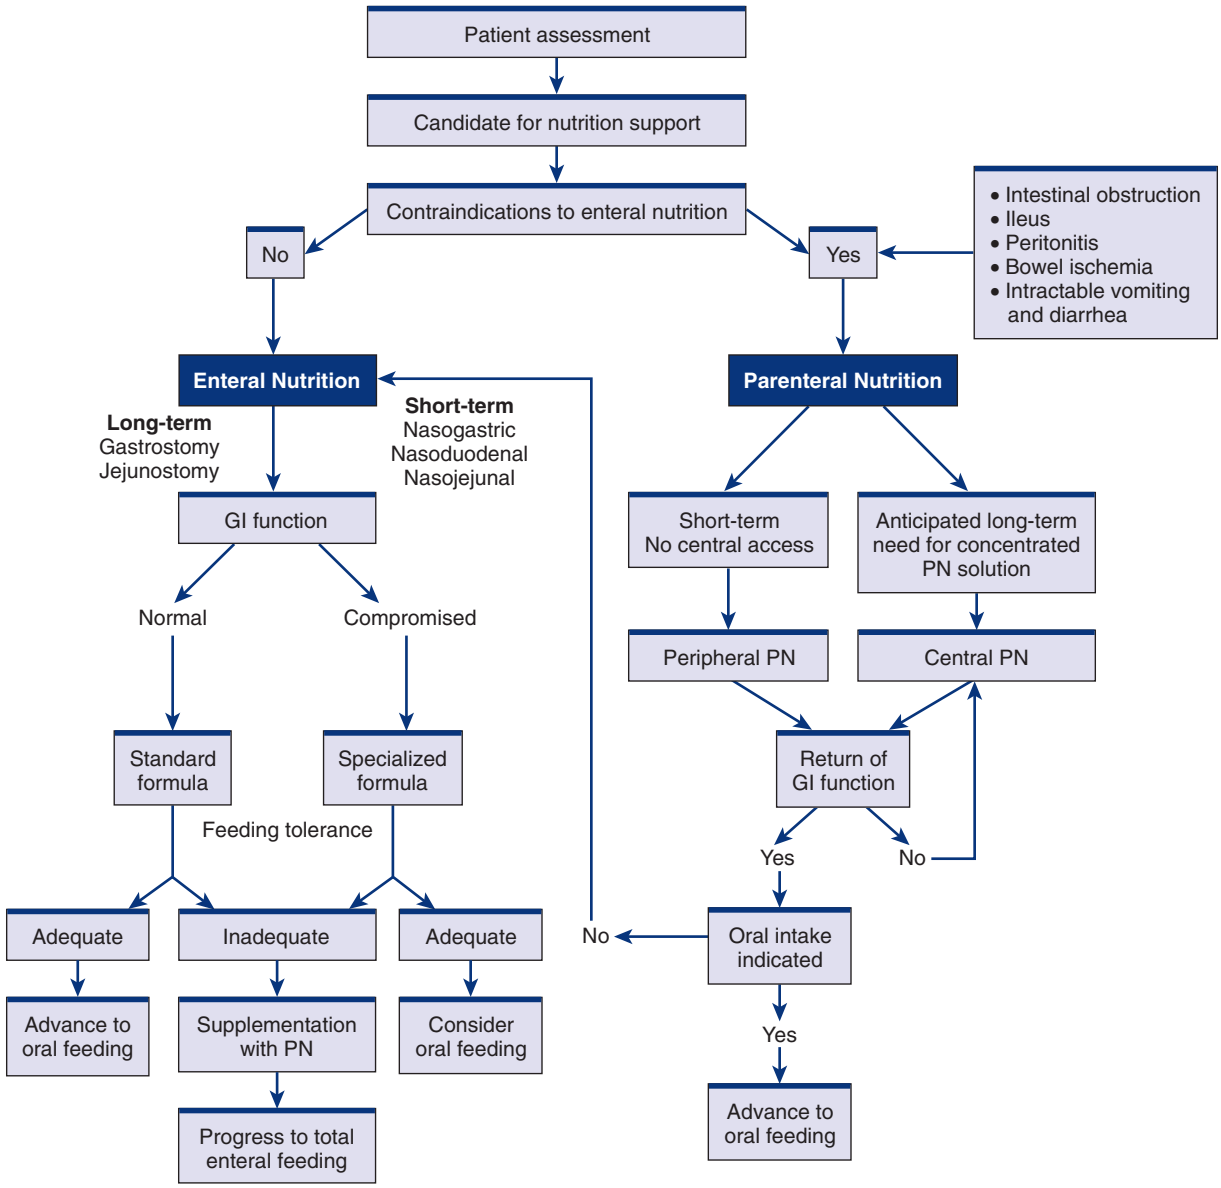

FIG. 40-5 Nutritional support algorithm.

commercially available products (e.g., Carnation Instant Breakfast, Ensure, Boost). If patients are unable to maintain or achieve adequate nutritional status, nutritional support may be necessary. For a decision-making plan related to nutritional support, see Fig. 40-5.

Enteral Nutrition

Enteral nutrition (EN), also known as **tube feeding,** is defined as nutrition (e.g., a nutritionally balanced liquefied food or formula) provided through the GI tract via a tube, catheter, or stoma that delivers nutrients distal to the oral cavity. EN may be ordered for the patient who has a functioning GI tract but is unable to take any or enough oral nourishment, or when it is unsafe to do so.

Indications for EN may include persons with anorexia, orofacial fractures, head and neck cancer, neurologic or psychiatric conditions that prevent oral intake, extensive burns, or critical illness (especially if mechanical ventilation is required), and those who are receiving chemotherapy or radiation therapy. EN is considered to be easily administered, safer, more physiologically efficient, and typically less expensive than parenteral nutrition (PN).

Common delivery options are continuous infusion by pump, intermittent infusion by gravity, intermittent bolus by syringe, and cyclic feedings by infusion pump. Continuous infusion is most often used with critically ill patients. Intermittent feeding may be preferred as the patient improves or is receiving EN at home.[36]

Nasally and orally placed tubes (orogastric, nasogastric [NG], nasoduodenal, or nasojejunal) are most commonly used for short-term feeding (less than 4 weeks). Nasoduodenal and nasojejunal tubes are transpyloric tubes. These tubes are used when pathophysiologic conditions such as risk of aspiration warrant feeding the patient below the pyloric sphincter. If the feedings are necessary for an extended time, other tubes are placed in the stomach or small bowel by surgical, endoscopic, or fluoroscopic procedures. (Fig. 40-6 shows the locations of commonly used enteral feeding tubes.)

Orogastric, Nasogastric, and Nasointestinal Tubes. Polyurethane or silicone feeding tubes are long, small in diameter, soft, and flexible, thereby decreasing the risk of mucosal damage from prolonged placement. These tubes are radiopaque, making their position readily identified by x-ray. Placement into the small intestine theoretically decreases the likelihood of regurgitation of contents into the esophagus and subsequent aspiration.[37] With the use of a stylet, these tubes can be placed in a comatose patient because the ability to swallow is not essential during insertion. However, the use of a stylet has been associated with increased risk for perforation.

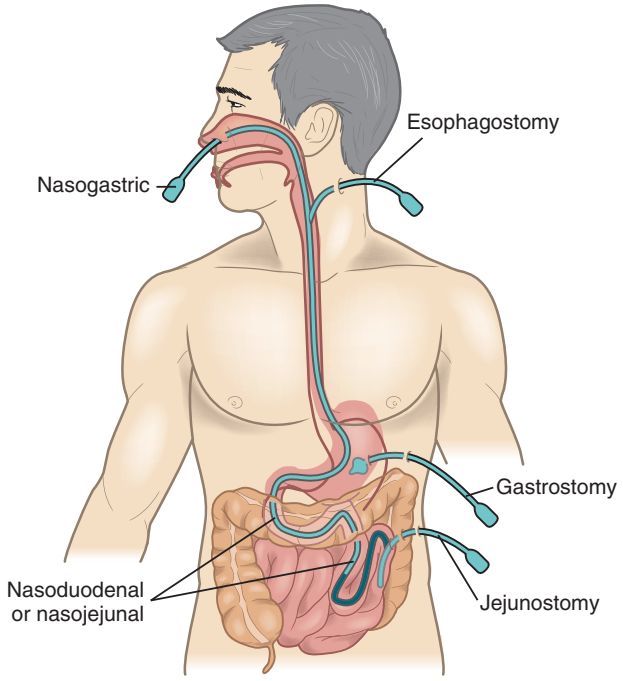

FIG. 40-6 Common enteral feeding tube placement locations.

Although the smaller feeding tubes have many advantages over wider-lumen tubes, such as the standard decompression NG tube, there are some disadvantages. Because of the small diameter, these tubes are more easily clogged when feedings are thick, and the tubes are more difficult to use for checking residual volumes. They are particularly prone to obstruction when oral drugs are not thoroughly crushed and dissolved in water before administration. Failure to flush the tubing before and after both drug administration and residual volume determinations can result in tube clogging. When the tube becomes clogged, it may necessitate removal and insertion of a new tube, adding to cost and patient discomfort. The tubes can become dislodged by vomiting or coughing and can also become knotted or kinked.

Gastrostomy and Jejunostomy Tubes. A gastrostomy tube may be used for a patient who requires EN over an extended time (see Fig. 40-6). Gastrostomy tubes can be placed surgically, radiologically, or endoscopically. The placement of a percutaneous endoscopic gastrostomy (PEG) tube is shown in Fig. 40-7. The patient must have an intact, unobstructed GI tract, and the esophageal lumen must be wide enough to pass the endoscope for PEG tube placement. PEG tube and radiologically placed gastrostomy tube procedures have fewer risks than surgical placement. The procedure requires IV sedation and local anesthesia. IV antibiotics are given before the procedure.

For the patient with chronic reflux, a jejunostomy (J-tube) with continuous feedings may be necessary to reduce the risk of aspiration.[38] Jejunostomy tubes are placed either endoscopically or with open or laparoscopic surgery.

Enteral feedings can be started within 24 to 48 hours after a surgically placed gastrostomy or jejunostomy tube without waiting for flatus or a bowel movement. PEG tube feeding may be started within 2 hours of insertion, although institutionally policies may vary.[39] The feeding tube is either premarked or marked at the skin insertion site. The tube is most often connected to a pump for continuous feeding.

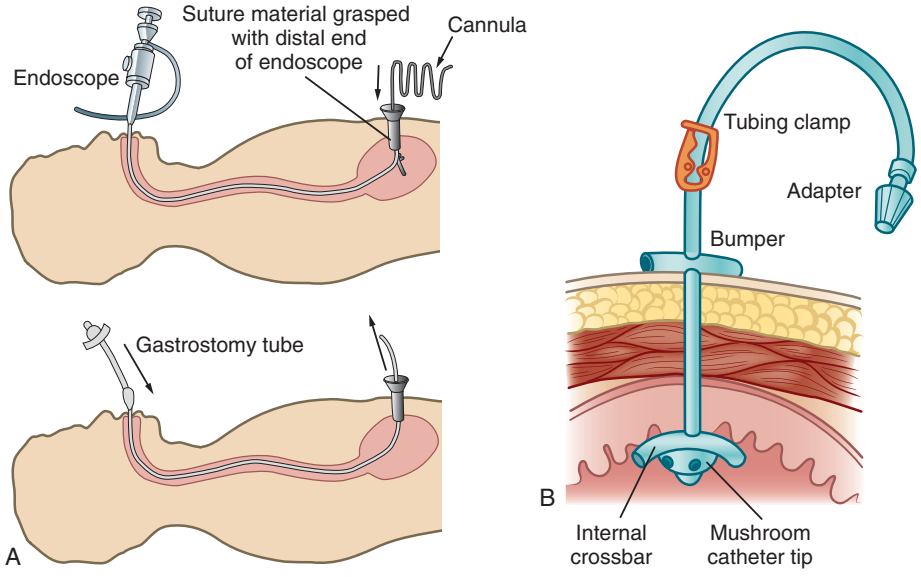

FIG. 40-7 Percutaneous endoscopic gastrostomy. **A,** Gastrostomy tube placement via percutaneous endoscopy. With use of endoscopy, a gastrostomy tube is inserted through the esophagus into the stomach and then pulled through a stab wound made in the abdominal wall. **B,** A retention disk and bumper secure the tube.

TABLE 40-11 PROBLEMS RELATED TO TUBE FEEDINGS

PROBLEMS AND CAUSES	CORRECTIVE MEASURES
Vomiting or Aspiration	
Improper placement of tube	• Replace tube in proper position. • Check tube position before beginning feeding and every 8 hr if continuous feedings.
Delayed gastric emptying, increased residual volume	• If gastric residual volume is ≥250 mL after second gastric residual check, consider a promotility agent. • If gastric residual volume is >500 mL, hold enteral nutrition and reassess patient tolerance.
Potential for aspiration	• Keep head of bed elevated to 30- to 45-degree angle. • Have patient sit up on side of bed or in chair. • Encourage ambulation unless contraindicated.
Dehydration	
Excessive diarrhea, vomiting	• Decrease rate or change formula. • Check drugs that patient is receiving, especially antibiotics. • Take care to prevent bacterial contamination of formula and equipment.
Poor fluid intake	• Increase intake and check amount and number of feedings. • Increase amount of fluid intake if appropriate.
High-protein formula	• Change formula.
Hyperosmotic diuresis	• Check blood glucose levels frequently. • Change formula.
Diarrhea	
Feeding too fast	• Decrease rate of feeding. • Change to continuous drip feedings.
Medications	• Check for drugs that may cause diarrhea (e.g., sorbitol in liquid medications, antibiotics).
Low-fiber formula	• Change to formula with more fiber.
Tube moving distally	• Properly secure tube before beginning feeding. • Check before each feeding or at least every 24 hr if continuous feedings.
Contamination of formula	• Refrigerate unused formula and record date opened. • Discard outdated formula every 24 hr. • Discard formula left standing for longer than manufacturer's guidelines. • 8 hr for ready-to-feed formulas (cans) • 4 hr for reconstituted formula • 24-48 hr for closed-system enteral formulas • Use closed system to prevent contamination. • Use sterile water for flushes.
Constipation	
Formula components	• Consult health care provider for change in formula to one with more fiber content. • Obtain laxative order.
Poor fluid intake	• Increase fluid intake if not contraindicated. • Give free water as well as formula. • Give total fluid intake of 30 mL/kg body weight.
Drugs	• Check for drugs that may be constipating.
Impaction	• Perform rectal examinations to check and manually remove feces if present.

Tube Feedings and Safety. You have a critical role to ensure that tube feedings are administered safely. Nursing management of tube feedings is briefly addressed in eTable 40-7 (available on the website for this chapter). Aspiration and dislodged tubes are two important safety concerns.

Patient Position. Proper patient positioning decreases the risk of aspiration. Elevate the head of bed to a minimum of 30 degrees, but preferably 45 degrees, to prevent aspiration. A reverse Trendelenburg position can be used to elevate the head of the bed, unless contraindicated, when a back rest elevation is not tolerated. If it is necessary to lower the head of the bed for a procedure, return the patient to an elevated position as soon as possible. Check institution policy for suspending feeding while the patient is supine. If intermittent delivery is used, the head should remain elevated for 30 to 60 minutes after feeding.[32]

Aspiration Risk. Evaluate all enterally fed patients for risk of aspiration. Before starting tube feedings, ensure that the tube is in the proper position. Maintain head-of-bed elevation as described above. Checking gastric residual volumes is important when feedings are administered into the stomach. For example, when the infusion rate is 100 mL/hr, the total infused volume of 400 mL may accumulate when gastric emptying is delayed. In addition, gastric secretions can increase the volume beyond 400 mL. With increased residual volume there is increased risk for aspiration of formula into the lungs.[36,37]

Residual Volumes. Check gastric residual volumes every 4 hours during the first 48 hours for gastrically fed patients. After the enteral feeding goal rate is achieved, gastric residual monitoring may be decreased to every 6 to 8 hours in non–critically ill patients or continued every 4 hours in critically ill patients. (Corrective measures for residual volume are described in Table 40-11.) Feeding tubes may need to be placed below the ligament of Treitz (jejunostomy) when gastric residual volumes consistently measure more than 500 mL. Do not obtain residual volumes for EN delivered through a jejunostomy tube.

Tube Position. Confirm tube position of newly inserted nasal or orogastric tubes before feeding or administering medications. Obtain x-ray confirmation to determine if a blindly placed NG or orogastric tube (small bore or large bore) is properly positioned in the GI tract before administering feedings or medications.

Smaller feeding tubes may be passed directly into the bronchus on insertion without any obvious respiratory manifestations. Do not rely on the auscultation method to differentiate between gastric and respiratory placement, or to differentiate between gastric and small bowel placement. Capnography, a direct monitor of breath-to-breath carbon dioxide level, may be used to detect inadvertent entry of tube into the trachea during insertion. X-ray confirmation is still needed to verify location before feeding. When in doubt, request an x-ray to determine tube location.[37,38]

Maintain proper placement of the tube after feedings are started. A small bowel tube may dislocate upward into the stomach, or the tube's tip can dislocate upward into the esophagus. To determine if a feeding tube has maintained the proper position, mark the exit site of the feeding tube at the time of the initial x-ray and observe for a change in the external tube length during feedings. Recheck the tube insertion length at regular intervals.

Observe for negative pressure when attempting to withdraw fluid from the feeding tube.[39] Negative pressure is more likely felt during attempts to aspirate fluid from a small bowel than from a gastric tube. Observe for unexpected changes in residual volume. An increase in gastric residual volume may indicate displacement of the small intestine tube into the stomach.[39] If a significant increase in the external length is observed, use other bedside tests to help determine whether the tube has become dislocated. These measures include assessment of aspirate color and pH. Because each of these measures has limitations, confirmation is done with more than one single bedside test. Use of technology such as electromagnetic tracking devices along with "tube teams" is associated with reduced tube misplacement.[40]

Complications Related to Tubes and Feedings. The types of problems in patients receiving tube feedings and corrective measures are presented in Table 40-11. When commercial products are used, the concentration, flavor, osmolarity, and amounts of protein, sodium, and fat vary according to the manufacturer. Most commercial formulas are lactose free. The concentrations range from 1 to 2 cal/mL, with most standard formulas providing between 1 and 1.5 cal/mL. Refeeding syndrome, which occasionally occurs with EN, is described below.

Osmolality of the solution is determined by the number and size of particles in solution. In feeding formulas the more hydrolyzed or broken down the nutrients, the greater the osmolality. The more calorically dense the formula, the less water it contains. Protein content greater than 16% can lead to dehydration unless the patient is given supplemental fluids or is sufficiently alert to request additional fluids.

Be aware of this potential problem and provide extra fluids through the feeding tube or, if permitted, by mouth. Tube feedings with high sodium content are contraindicated in the patient with cardiovascular problems, such as heart failure. High fat content is not advocated for a patient with short bowel syndrome or ileocecal resection because of impaired fat absorption.

The registered dietitian is an important health care team member in providing EN. Some institutions have nutritional support teams composed of a physician, nurse, dietitian, and pharmacist. The team's function is to oversee the nutritional support of select inpatients and outpatients. The nutritional support nurse on that team is a key resource for issues regarding patients' nutrition.

In patients receiving gastrostomy or jejunostomy feeding, be alert to two possible problems: (1) skin irritation and (2) dislodgment of the tube. Skin care around the tube site is important because the action of the digestive juices irritates the skin. Assess the skin around the feeding tube daily for signs of redness and maceration. To keep the skin clean and dry, initially rinse it with sterile water and then dry it. Once the site has healed, wash with mild soap and water. A protective ointment (zinc oxide, petroleum gauze) or a skin barrier (karaya, Stomahesive) may be used on the skin around the tube. Other types of drain or tube pouches may be used if the skin is irritated. An enterostomal therapist can provide assistance if these issues arise.

Teach the patient and caregiver how to care for the feeding tube. Accidental tube removal can result in delayed feedings and potential discomfort with tube replacement. Patient teaching includes skin care, care of the tube, and complete information about feeding administration and potential complications.

DELEGATION DECISIONS

Nasogastric and Gastric Tubes and Enteral Feedings

Role of Registered Nurse (RN)
- Insert nasogastric (NG) tube for unstable patient.
- Irrigate NG or gastrostomy tube for unstable patient.
- Insert nasointestinal tube.
- After tube placement is verified, administer bolus or continuous enteral feeding for unstable patient.
- Administer medications through the NG or gastrostomy tube to unstable patient.
- Evaluate nutritional status of patient receiving enteral feedings.
- Monitor for complications related to tubes and enteral feedings.
- Develop plan for gastrostomy or jejunostomy tube care.
- Teach patient and caregiver about home enteral feeding and gastrostomy or jejunostomy tube care.
- Evaluate for therapeutic effect of NG tube connected to suction (e.g., decreased nausea or distention).

Role of Licensed Practical/Vocational Nurse (LPN/LVN)
- Insert NG tube for stable patient.
- Irrigate NG and gastrostomy tubes.
- Administer bolus or continuous enteral feeding for stable patient.
- Remove NG tube.
- Administer medications through NG or gastrostomy tube to stable patient.
- Provide skin care around gastrostomy or jejunostomy tubes.

Role of Unlicensed Assistive Personnel (UAP)
- Provide oral care to patient with NG, gastrostomy, or jejunostomy tube.
- Weigh patient who is receiving enteral feeding.
- Position and maintain patient receiving enteral feeding with the head of bed elevated.
- Notify RN or LPN about patient symptoms (e.g., nausea, diarrhea) that may indicate problems with enteral feedings.
- Alert RN or LPN about enteral feeding infusion pump alarms.
- Empty drainage devices and measure output.

An *enteral feeding misconnection* is an inadvertent connection between an enteral feeding system and a nonenteral system such as an IV line, a peritoneal dialysis catheter, or a tracheostomy tube cuff.[1] With an enteral feeding misconnection, nutritional formula intended for administration into the GI tract is administered via the wrong route, resulting in serious and potentially life-threatening patient complications. Nursing interventions aimed at decreasing the risk of enteral feeding misconnections are found in Table 40-12. eNursing Care Plan 40-1 for patients receiving EN is on the website for this chapter.

GERONTOLOGIC CONSIDERATIONS

ENTERAL NUTRITION

EN strategies, including orogastric, NG, nasointestinal, and gastrostomy feedings, are used in the older patient to improve nutritional status. Because of physiologic changes associated with aging, the older adult is more vulnerable to complications associated with nutritional interventions, especially fluid and electrolyte imbalances. Complications such as diarrhea can leave the patient dehydrated. Decreased thirst perception or impaired cognitive function decreases the patient's ability to seek additional fluids.

With aging, there is an increased risk of glucose intolerance. As a result, the older patient may be more susceptible to hyperglycemia in response to the high carbohydrate load of some

TABLE 40-12 DECREASING RISK OF ENTERAL FEEDING MISCONNECTIONS

1. Teach visitors, LPN/LVNs, and UAP to notify nurse if an enteral feeding line becomes disconnected.
2. Teach visitors, LPN/LVNs, and UAP not to reconnect enteral feeding lines.
3. Do not modify or adapt IV or feeding devices because you may compromise the safety features incorporated into their design.
4. Don't force connections if device parts do not seem to fit properly. Ill-fitting pieces indicate a problem.
5. When making a reconnection, routinely trace lines back to their origins and then ensure that they are secure.
6. When patient arrives on a new unit or setting or during shift handoff, recheck connections and trace all tubes.
7. Route tubes and catheters that have different purposes in unique and standardized directions (e.g., route IV lines toward the patient's head, and route enteral lines toward the feet).
8. Package together all parts needed for enteral feeding and reduce the availability of additional adapters and connectors. This will minimize the availability of dissimilar tubes or catheters that could be improperly connected.
9. Label or color-code feeding tubes and connectors, and teach staff about the labeling or color-coding process in the institution's enteral feeding system.
10. Be sure to identify and confirm the solution's label, since a three-in-one parenteral nutrition solution can appear similar to an enteral nutrition formulation bag. Label the bags with large, bold statements such as "WARNING! For Enteral Use Only—NOT for IV Use."
11. Ensure that all connections are made under proper lighting conditions.
12. Follow your facility's protocol for reporting adverse events and near misses.

Adapted from Millin CJ, Brooks M: Reduce and report enteral feeding tube misconnections, *Nursing* 40:60, 2010; and Guenter P, Hicks RW, Simmons D, et al: Enteral feeding misconnections: a consortium position statement, *Jt Comm J Qual Patient Saf* 34:285, 2008.

enteral feeding formulas. If the older adult has compromised cardiovascular function (e.g., heart failure), he or she will have a decreased ability to handle large volumes of formula. In this situation the use of more concentrated formulas (2.0 cal/mL) may be warranted. The older adult also is at increased risk for aspiration caused by gastroesophageal reflux disease (GERD), delayed gastric emptying, hiatal hernia, or diminished gag reflex. Physical mobility, fine motor movement, and visual system changes associated with aging may contribute to difficulties in managing EN in the home setting.

Parenteral Nutrition

Parenteral nutrition (PN) refers to the administration of nutrients by a route other than the GI tract (e.g., the bloodstream). It is used when the GI tract cannot be used for the ingestion, digestion, and absorption of essential nutrients. PN is a relatively safe and practical method of delivering complete nutritional support.

Regular IV solutions of 5% dextrose (5 g dextrose/dL) in water (D_5W) or 5% dextrose in lactated Ringer's solution (D_5LR) contain no protein and have approximately 170 cal/L. The average adult requires a minimum of 1200 to 1500 cal/day to carry out normal physiologic functions. Patients who sustain severe injury, surgery, or burns and those who are malnourished as a result of medical treatment or disease processes have greatly increased nutritional needs. The volume of regular dextrose solutions needed to meet the caloric requirements exceeds the capacity of the cardiovascular system. Table 40-13 lists common indications for the use of PN.

TABLE 40-13 INDICATIONS FOR PARENTERAL NUTRITION*

- Chronic severe diarrhea and vomiting
- Complicated surgery or trauma
- GI obstruction
- Intractable diarrhea
- Severe anorexia nervosa
- Severe malabsorption
- Short bowel syndrome
- GI tract anomalies and fistulae

*This list is not all-inclusive.

Composition. Commercially prepared PN base solutions are available. These base solutions contain dextrose and protein in the form of amino acids. The pharmacy adds the prescribed electrolytes (e.g., sodium, potassium, chloride, calcium, magnesium, and phosphate), vitamins, and trace elements (e.g., zinc, copper, chromium, and manganese) to customize and meet the patient's needs. A three-in-one or total nutrient admixture containing an IV fat emulsion, dextrose, and amino acids is widely used.

Calories. Calories in PN are supplied primarily by carbohydrates in the form of dextrose and by fat in the form of fat emulsion. The administration of 100 to 150 g of dextrose daily (1 g provides approximately 3.4 calories, as opposed to oral carbohydrates, which provide 4 calories) has a protein-sparing effect. Adequate nonprotein calories in the form of glucose and fat must be provided to allow use of amino acids for wound healing and not for energy. However, overfeeding can lead to metabolic complications. To minimize these problems, an energy intake of 25 to 35 cal/kg/day in a nonobese patient is often recommended.

The U.S. FDA has approved the use of 10%, 20%, and 30% fat-emulsion solutions. Fat emulsions provide approximately 1 cal/mL (10% solution) or 2 cal/mL (20% solution). The contents of fat emulsion are primarily soybean or safflower triglycerides with egg phospholipids added as an emulsifier.

IV fat emulsions should provide up to 30% of total calories. Most stable patients receive 1 g/kg/day, and the maximum daily lipid dose is 2.5 g/kg/day. Critically ill patients may not tolerate this dose and may receive less than 1 g/kg/day.[31,41] Serum triglyceride levels are determined at the beginning of PN and then monitored closely after that. IV fat emulsions administered separately should be administered over a course of 8 to 10 hours, and the infusion rate should not exceed 0.11 g/kg/hr.[41,42]

It is becoming more common to administer lipid-free PN for the first 3 to 5 days of a critical illness because of the potential for omega-6 fatty acids to produce proinflammatory mediators.[31,41]

Nausea, vomiting, and elevated temperature have been reported, especially when lipids are infused quickly. The administration of fat emulsion is contraindicated in the patient with a disturbance in fat metabolism such as hyperlipidemia. Fat emulsions are used cautiously in the patient at risk for fat embolism (e.g., fractured femur) and the patient with an allergy to eggs or soybeans. Lipid emulsions are also used cautiously in patients with pancreatitis, bleeding disorders, liver failure, and respiratory disease.

Protein. The normal healthy person of average body size needs approximately 45 to 65 g of protein daily. Protein should be provided at the rate of 1 to 1.5 g/kg/day depending on the

patient's needs. In a nutritionally depleted patient who is also under the stress of illness or surgery, protein requirements can exceed 150 g/day (1.5 to 2 g/kg/day) to ensure a positive nitrogen balance. Burn patients, who are often on PN, EN, and oral food, may need upward of 2 g/kg protein. Protein needs may be lower than 1 g/kg and restricted in individuals with end-stage renal disease who are not on dialysis.

Electrolytes. Individual requirements should be assessed daily at the beginning of therapy and then several times a week as the treatment progresses. The following are ranges for average daily electrolyte requirements for adult patients without renal or hepatic impairment:[37]

- Sodium: 1 to 2 mEq/kg
- Potassium: 1 to 2 mEq/kg
- Chloride: as needed to maintain acid-base balance
- Magnesium: 8 to 20 mEq
- Calcium: 10 to 15 mEq
- Phosphate: 20 to 40 mmol

The exact amount of electrolytes needed depends on the patient's health problem and on electrolyte levels as determined by blood testing.

Trace Elements and Vitamins. Zinc, copper, chromium, manganese, selenium, molybdenum, and iodine supplements may be added according to the patient's condition and needs. Levels of these elements are monitored in the patient receiving PN, and the health care provider may order additional amounts added to the solutions.

The daily addition of a multivitamin preparation to the PN generally meets the vitamin requirements.

Methods of Administration. PN may be administered as central PN or peripheral parenteral nutrition (PPN). Both central PN and PPN are used in a patient who is not a candidate for EN. The patient receiving PN must be able to tolerate a large volume of fluid.

Central Parenteral Nutrition. *Central PN* is indicated when long-term support is necessary or when the patient has high protein and caloric requirements. Central PN may be given through a central venous catheter that originates at the subclavian or jugular vein and whose tip lies in the superior vena cava (see Fig. 17-18). Central PN can also be given using peripherally inserted central catheters (PICCs) that are placed into the basilic or cephalic vein and then advanced into the distal end of the superior vena cava (see Fig. 17-19).

Peripheral Parenteral Nutrition. *PPN* is administered through a peripherally inserted catheter or vascular access device, which uses a large vein. PPN is used when (1) nutritional support is needed for only a short time, (2) protein and caloric requirements are not high, (3) the risk of a central catheter is too great, or (4) PN is used to supplement inadequate oral intake.

Comparison of Central and Peripheral Parenteral Nutrition. Central PN and PPN differ in tonicity, which is measured in milliosmoles (mOsm; the concentration of particles in a fluid). Blood is isotonic and measures approximately 280 mOsm/L. The standard IV solutions of D_5W and normal saline are essentially isotonic. Central PN solutions are hypertonic, measuring at least 1600 mOsm/L. The high glucose content ranges from 20% to 50%. Central PN must be infused in a large central vein so that rapid dilution can occur. The use of a peripheral vein for hypertonic, central PN solutions would cause irritation and thrombophlebitis. Nutrients can be infused using smaller volumes than PPN. PPN solutions are also hypertonic (as much as 20% glucose), but less so than with central PN, and can be safely administered through a large peripheral vein, although phlebitis can occur. Another potential complication of PPN is fluid overload.

TABLE 40-14 COMPLICATIONS OF PARENTERAL NUTRITION

Infection
- Fungus
- Gram-positive bacteria
- Gram-negative bacteria

Metabolic Problems
- Hyperglycemia, hypoglycemia
- Altered renal function
- Essential fatty acid deficiency
- Electrolyte and vitamin excesses and deficiencies
- Trace mineral deficiencies
- Hyperlipidemia

Catheter-Related Problems
- Air embolus
- Pneumothorax, hemothorax, and hydrothorax
- Hemorrhage
- Dislodgment
- Thrombosis of vein
- Phlebitis

NURSING MANAGEMENT PARENTERAL NUTRITION

Nursing management of patients receiving PN is presented in eTable 40-8 and eNursing Care Plan 40-2 (available on the website for this chapter).

COMPLICATIONS

Refeeding syndrome is characterized by fluid retention and electrolyte imbalances (hypophosphatemia, hypokalemia, hypomagnesemia) (Table 40-14). Conditions that predispose patients to refeeding syndrome include long-standing malnutrition states such as chronic alcoholism, vomiting and diarrhea, chemotherapy, and major surgery. Refeeding syndrome can occur any time a malnourished patient is started on aggressive nutritional support. Hypophosphatemia is the hallmark of refeeding syndrome and is associated with serious outcomes, including cardiac dysrhythmias, respiratory arrest, and neurologic disturbances (e.g., paresthesias).

HOME NUTRITIONAL SUPPORT

Home PN or EN is an accepted mode of nutritional therapy for the person who does not require hospitalization but who requires continued nutritional support. Some patients have been successfully treated at home for many months and even years. It is important for you to teach the patient and caregiver about catheter or tube care, proper technique in mixing and handling of the solutions and tubing, and side effects and complications.

Home nutritional therapies are expensive. For patients to be reimbursed for expenses, specific criteria must be met. The discharge planning team needs to be involved early in the admission to help plan for such issues. Home nutritional support may also be a burden on the patient and the caregivers and may affect quality of life. Tell the family about support groups such as the Oley Foundation *(www.oley.org)* that provide peer support and advocacy.

EATING DISORDERS

Eating disorders are primarily psychiatric disorders and occur more often in women. Men are also at risk, but are less likely to seek treatment because eating disorders are perceived to be a women's disease.[43] The notion that eating disorders occur more

frequently in whites is being challenged. African Americans, Asian Americans, and Mexican Americans are also at risk for eating disorders.[44,45] Patients with eating disorders may be hospitalized for fluid and electrolyte alterations; cardiac dysrhythmias; nutritional, endocrine, and metabolic disorders; and menstrual problems.[46] A number of nutritional problems associated with these disorders require you to implement a nutritional plan of care.

The three most common types of eating disorders are anorexia nervosa, bulimia nervosa, and binge-eating disorder.

Anorexia Nervosa

Anorexia nervosa is characterized by a self-imposed weight loss, endocrine dysfunction, and a distorted psychopathologic attitude toward weight and eating.[47] Anorexia nervosa is a serious mental illness affecting 1.2% to 2.2% of people during their lifetime, and it occurs more frequently in women.[44] Anorexia nervosa clinically manifests as abnormal weight loss, deliberate self-starvation, intense fear of gaining weight, *lanugo* (soft, downy hair covering the body except the palms and soles), refusal to eat, continuous dieting, hair loss, sensitivity to cold, compulsive exercise, absent or irregular menstruation, dry and yellowish skin, and constipation. Signs of malnutrition are noted during the physical examination.

Diagnostic studies often show iron-deficiency anemia and an elevated blood urea nitrogen level that reflects marked intravascular volume depletion and abnormal renal function. Lack of potassium in the diet and loss of potassium in the urine lead to potassium deficiency. Manifestations of potassium deficiency include muscle weakness, cardiac dysrhythmias, and renal failure. Leukopenia, hypoglycemia, hyponatremia, hypomagnesemia, and hypophosphatemia may also be present.

Multidisciplinary treatment must involve a combination of nutritional support and psychiatric care.[48] Nutritional rehabilitation focuses on reaching and maintaining a healthy weight, normal eating patterns, and perception of hunger and satiety. Hospitalization may be necessary if the patient has medical complications that cannot be managed in an outpatient therapy program. Nutritional repletion must be closely supervised to ensure consistent and ongoing weight gains. Refeeding syndrome is a rare but serious complication of refeeding programs. The use of EN or PN may be necessary.

Improved nutrition, however, is not a cure for anorexia nervosa. The underlying psychiatric problem must be addressed by identification of the disturbed patterns of individual and family interactions, followed by individual and family counseling.

Bulimia Nervosa

Bulimia nervosa is a disorder characterized by frequent binge eating and self-induced vomiting associated with loss of control related to eating and a persistent concern with body image.[47] Individuals with bulimia nervosa may have normal weight for height, or their weight may fluctuate with bingeing and purging. They may also abuse laxatives, diuretics, exercise, or diet drugs. They may have signs of frequent vomiting, such as macerated knuckles, swollen salivary glands, broken blood vessels in the eyes, and dental problems. The individual with bulimia nervosa goes to great lengths to conceal abnormal eating habits. Abnormal laboratory parameters, including hypokalemia, metabolic alkalosis, and elevated serum amylase, may occur with frequent vomiting.[47]

The cause of bulimia remains unclear but is thought to be similar to that of anorexia nervosa. Substance abuse, anxiety, affective disorders, and personality disturbances have been reported among persons with bulimia. Over time, problems associated with bulimia become increasingly hard to deal with effectively. A treatment combination of psychologic counseling and diet therapy is essential.[48]

Antidepressants are helpful for some but not all patients with bulimia. Education and emotional support for the patient and family are vital. Support groups such as the National Association of Anorexia Nervosa and Associated Disorders (ANAD) (*www.anad.org*) are helpful to those affected by these disorders.

Binge-eating disorder is less severe than bulimia nervosa and anorexia nervosa. Individuals with binge-eating disorder do not have a distorted body image and are often overweight or obese.[49]

CASE STUDY

Undernutrition

iStockphoto/Thinkstock

Patient Profile

M.S. is a 70-yr-old white woman who is 5 ft, 4 in tall and weighs 100 lb. She was recently admitted to the inpatient medical unit.

Subjective Data

- Reports 30-lb weight loss in past 2 mo
- Recently had a thrombotic stroke with hemiparesis and dysphagia
- Has a history of rheumatoid arthritis
- Has had nothing by mouth for the past 24 hr and just started enteral nutrition via PEG tube
- Lives with her daughter, who is at her bedside

Objective Data

Physical Examination

- Has left-sided weakness
- BP is 150/90 mm Hg
- A PEG tube was recently placed

Laboratory Results

- Serum albumin 2.9 g/dL
- Prealbumin 11.0 mg/dL

Discussion Questions

1. What are M.S.'s risk factors for malnutrition?
2. What is her BMI?
3. What are contributing factors to her developing dysphagia and malnutrition?
4. What should you include in a successful weight gain program for M.S.?
5. Which possible complications of enteral nutrition could M.S. be at risk for developing?
6. ***Priority Decision:*** What is the priority of the nursing care for M.S.?
7. ***Priority Decision:*** Based on the assessment data presented, write one or more appropriate nursing diagnoses. Are there any collaborative problems?
8. ***Delegation Decision:*** How would you use unlicensed assistive personnel (UAP) to care for M.S.?
9. ***Evidence-Based Practice:*** M.S.'s daughter tells you that her mother's abdomen appears bloated and she wonders if she should massage it.

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg.*

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The percentage of daily calories for a healthy individual consists of
   - **a.** 50% carbohydrates, 25% protein, 25% fat, and <10% of fat from saturated fatty acids.
   - **b.** 65% carbohydrates, 25% protein, 25% fat, and >10% of fat from saturated fatty acids.
   - **c.** 50% carbohydrates, 40% protein, 10% fat, and <10% of fat from saturated fatty acids.
   - **d.** 40% carbohydrates, 30% protein, 30% fat, and >10% of fat from saturated fatty acids.
2. During starvation, the order in which the body obtains substrate for energy is
   - **a.** visceral protein, skeletal protein, fat, glycogen.
   - **b.** glycogen, skeletal protein, fat stores, visceral protein.
   - **c.** visceral protein, fat stores, glycogen, skeletal protein.
   - **d.** fat stores, skeletal protein, visceral protein, glycogen.
3. A complete nutritional assessment including anthropometric measurements is important for the patient who
   - **a.** has a BMI of 25.5 kg/m^2.
   - **b.** complains of frequent nocturia.
   - **c.** reports a 5-year history of constipation.
   - **d.** reports an unintentional weight loss of 10 lb in 2 months.
4. The nurse confirms initial placement of a blindly inserted small-bore NG feeding tube by
   - **a.** x-ray.
   - **b.** air insufflation.
   - **c.** observing patient for coughing.
   - **d.** pH measurement of gastric aspirate.
5. A patient is receiving peripheral parenteral nutrition. The parenteral nutrition solution is completed before the new solution arrives on the unit. The nurse administers
   - **a.** 20% intralipids.
   - **b.** 5% dextrose solution.
   - **c.** 0.45% normal saline solution.
   - **d.** 5% lactated Ringer's solution.
6. A patient with anorexia nervosa shows signs of malnutrition. During initial refeeding, the nurse carefully assesses the patient for
   - **a.** hyperkalemia.
   - **b.** hypoglycemia.
   - **c.** hypercalcemia.
   - **d.** hypophosphatemia.

1. a, 2. b, 3. d, 4. a, 5. b, 6. d

LEARNING OUTCOMES

1. Discuss the epidemiology and etiology of obesity.
2. Compare the classification systems for determining a person's body size.
3. Explain the health risks associated with obesity.
4. Discuss nutritional therapy and exercise plans for the obese patient.
5. Describe the different bariatric surgical procedures used to treat obesity.
6. Describe the nursing management related to conservative and surgical therapies for obesity.
7. Describe the etiology, clinical manifestations, and nursing and collaborative management of metabolic syndrome.

KEY TERMS

bariatric surgery, p. 916
body mass index (BMI), p. 906
lipectomy, p. 917
metabolic syndrome, p. 921
obese, p. 906
overweight, p. 906
severely obese, p. 906
waist-to-hip ratio (WHR), p. 907

OBESITY

Obesity is an excessively high amount of body fat or adipose tissue (Fig. 41-1). Obesity is a major health problem because it increases the risk of numerous other diseases such as diabetes and cancer.[1]

Classifications of Body Weight and Obesity

An important part of your patient assessment is to determine and classify a patient's body weight. A number of assessment methods are available, including body mass index (BMI), waist circumference, waist-to-hip ratio (WHR), and body shape. The most widely used and endorsed measures are BMI and waist circumference.[2] These measures are cost-effective with acceptable reliability and are easily used in all practice settings.

Body Mass Index. The most common measure of obesity is the **body mass index (BMI).** BMI is calculated by dividing a person's weight (in kilograms) by the square of the height in meters (Fig. 41-2). Individuals with a BMI less than 18.5 kg/m^2 are considered underweight, whereas those with a BMI between 18.5 and 24.9 kg/m^2 reflect a normal body weight. A BMI of 25 to 29.9 kg/m^2 is classified as being **overweight,** and those with values at 30 kg/m^2 or above are considered **obese.** The term **severely** *(morbidly, extremely)* **obese** is used for those with a BMI greater than 40 kg/m^2 (eFig. 41-1 on the website shows individuals who are severely obese).

Table 41-1 shows the classification of overweight and obesity by BMI. The BMI, which provides an overall assessment of fat mass, must be considered in relation to the patient's age, gender, and body build. For example, a body builder may have a BMI associated with obesity but because of a high

FIG. 41-1 Obesity is an epidemic in the United States. (iStockphoto/Thinkstock)

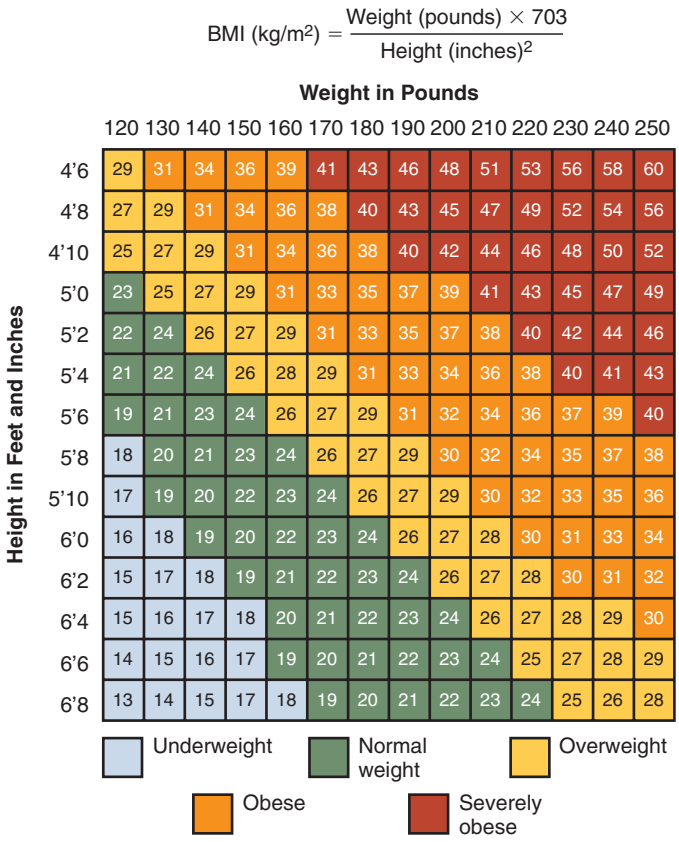

FIG. 41-2 Body mass index (BMI) chart. Healthy weight: BMI 18 to 24.9 kg/m^2; overweight: BMI 25 to 29.9 kg/m^2; obesity: BMI 30 kg/m^2. BMI = weight (kg)/height (m^2).

muscle mass, the BMI would not be an accurate assessment. In contrast, in individuals who have lost body mass (e.g., older adults), the BMI would underestimate the degree of obesity. For this reason, other measures must be combined with the BMI for an accurate evaluation of a person's weight.

Waist Circumference. *Waist circumference* is another way to assess and classify a person's weight (see Table 41-1). People who have visceral fat with truncal obesity are at an increased risk for cardiovascular disease and metabolic syndrome (discussed later in this chapter). Health risks increase if the waist circumference is greater than 40 inches in men and greater than 35 inches in women.[1]

Waist-to-Hip Ratio. The **waist-to-hip ratio (WHR)** is another tool used to assess obesity. This ratio is a method of describing the distribution of both subcutaneous and visceral adipose tissue. The ratio is calculated by using the waist measurement divided by the hip measurement. A WHR less than 0.8 is optimal, and a WHR greater than 0.8 indicates more truncal fat, which puts the individual at a greater risk for health complications.

Body Shape. *Body shape* is another method of identifying those who are at a higher risk for health problems (Table 41-2). Individuals with fat located primarily in the abdominal area, an *apple-shaped body,* have *android obesity*. Those with fat distribution in the upper legs, a *pear-shaped body*, have *gynoid obesity*. Genetics has an important role in determining a person's body shape. Weight and shape are influenced by genetics.[3]

Epidemiology of Obesity

Currently, more than 35% of adults in the United States are obese. Unless Americans change their ways, 50% of the U.S. population will be obese by 2030.[4] Women having a slightly higher incidence of obesity than men. When those who are

TABLE 41-1 CLASSIFICATION OF OVERWEIGHT AND OBESITY

			Disease Risk Based on Waist Circumference*	
	BMI (kg/m^2)	Obesity Class	Men ≤40 in (102 cm) Women ≤35 in (89 cm)	Men >40 in (102 cm) Women >35 in (89 cm)
Underweight	<18.5	—	—	—
Normal†	18.5-24.9	—	—	—
Overweight	25.0-29.9	—	Increased	High
Obese	30.0-34.9	Class I	High	Very high
	35.0-39.9	Class II	Very high	Very high
Severely obese	≥40.0	Class III	Extremely high	Extremely high

*Disease risk for type 2 diabetes, hypertension, and cardiovascular disease relative to person of normal weight.

†Increased waist circumference can also be a marker for increased risk in persons of normal weight.

BMI, Body mass index.

TABLE 41-2 RELATIONSHIP BETWEEN BODY SHAPE AND HEALTH RISKS

Body Shape	Characteristics	Health Risks
Gynoid (pear) 	• Fat mainly located in the upper legs • Has a better prognosis but difficult to treat	• Osteoporosis • Varicose veins • Cellulite • Subcutaneous fat traps and stores dietary fat • Trapped fatty acids stored as triglycerides
Android (apple) 	• Fat primarily located in abdominal area • Fat also distributed over upper body (neck, arms, shoulders) • Greater risk for obesity-related complications	• Heart disease • Diabetes mellitus • Breast cancer • Endometrial cancer • Visceral fat more active, causing • ↓ Insulin sensitivity • ↑ Triglycerides • ↓ HDL cholesterol • ↑ BP • ↑ Free fatty acid release into blood

HDL, High-density lipoprotein.

CULTURAL & ETHNIC HEALTH DISPARITIES

Obesity

- African Americans and Hispanics have a higher prevalence of obesity than whites.
- Among women, African Americans have the highest prevalence of being overweight or obese, and 15% are severely obese.
- Among men, Mexican Americans have the highest prevalence of being overweight or obese.
- African American and Hispanic women with low incomes appear to have the greatest likelihood of being overweight when compared with other socioeconomic groups.
- Native Americans have a higher prevalence of being overweight than the general population.
- Among Native Americans ages 45 to 74, more than 30% of women are overweight and more than 40% are obese.
- Asian Americans have the lowest prevalence of being overweight and obese compared with the general population.

overweight are included, the incidence of the adult population with a BMI greater than 25 kg/m^2 increases to more than 68%.[5]

The highest prevalence of obesity occurs between ages 40 and 59 for women and after 60 years of age for men.[5] African Americans have the highest incidence of obesity followed by Hispanics (see Cultural & Ethnic Health Disparities box above).

Obesity in adulthood is often a problem that begins in childhood or adolescence. Nearly one third of children and teens are currently obese or overweight. It is estimated that almost half of overweight adults were overweight in childhood, and two thirds of obese children remained obese into adulthood.[6] Reversing the childhood obesity crisis is key to addressing the overall obesity epidemic.

HEALTHY PEOPLE

Health Impact of Maintaining a Healthy Weight

- Reduces the risk of developing type 2 diabetes mellitus
- Increases chance of longevity and better quality of life
- Lowers the risk of hypertension and elevated cholesterol
- Reduces the risk of heart disease, stroke, and gallbladder disease
- Reduces the likelihood of breathing problems, including sleep apnea and asthma
- Decreases the risk of developing osteoarthritis, low back pain, and certain types of cancers

Etiology and Pathophysiology

Obesity is an increase in body weight beyond the body's physical requirements. This results in an abnormal increase and accumulation of fat cells. However, the processes leading to and sustaining the obese state are complex and still undergoing investigation.

In obesity, there is an increase in the number of adipocytes *(hyperplasia)* and an increase in their size *(hypertrophy)*. Adipocyte *hypertrophy* is a process by which adipocytes can increase their volume several thousand–fold to accommodate large increases in lipid storage. In addition, preadipocytes are triggered to become adipocytes once storage of existing fat cells is exceeded.[2] This process primarily occurs in the visceral (intraabdominal) and subcutaneous tissues. The process of *hyperplasia* (increase in numbers) of adipocytes is greatest from infancy through adolescence.

The majority of obese persons have *primary obesity,* which is excess calorie intake over energy expenditure for the body's metabolic demands. Others have *secondary obesity,* which can result from various congenital anomalies, chromosomal anomalies, metabolic problems, or central nervous system lesions and disorders.

The cause of obesity involves significant genetic and biologic factors that are highly influenced by environmental and psychosocial factors. Each of these factors can and should be considered individually, but in reality they are interrelated.

Genetic Link

Studies of twins, adoptees, and families all suggest the existence of genetic factors in obesity.[7,8] The heritability of obesity estimated from twin studies is high, with only slightly lower values in twins raised apart than in those raised together. Similarly, in adoptees the children's BMI correlated with that of their biologic parents rather than their adoptive parents.[9] Estimates of obesity as an inherited problem are more than 50%.[8]

A number of genes have been identified as being linked to obesity. Genes actually may influence how calories are stored and energy released. "Energy-thrifty" genes, once protective against long periods where food was not available, are now maladaptive in societies where food availability is no longer a primary issue.[7] Genes may be responsible for why two individuals living in the same environment can vary considerably in body size.

A strong link exists between a gene known as *FTO* (fat mass and obesity-associated gene) and BMI. Variants of this gene may explain why some people become overweight whereas others do not. People with two copies of a certain allele at the *FTO* gene weigh 7 to 8 lb more and have a greater risk of obesity than those who do not have the risk allele.[10] More research is needed to better understand the role of genes in obesity.

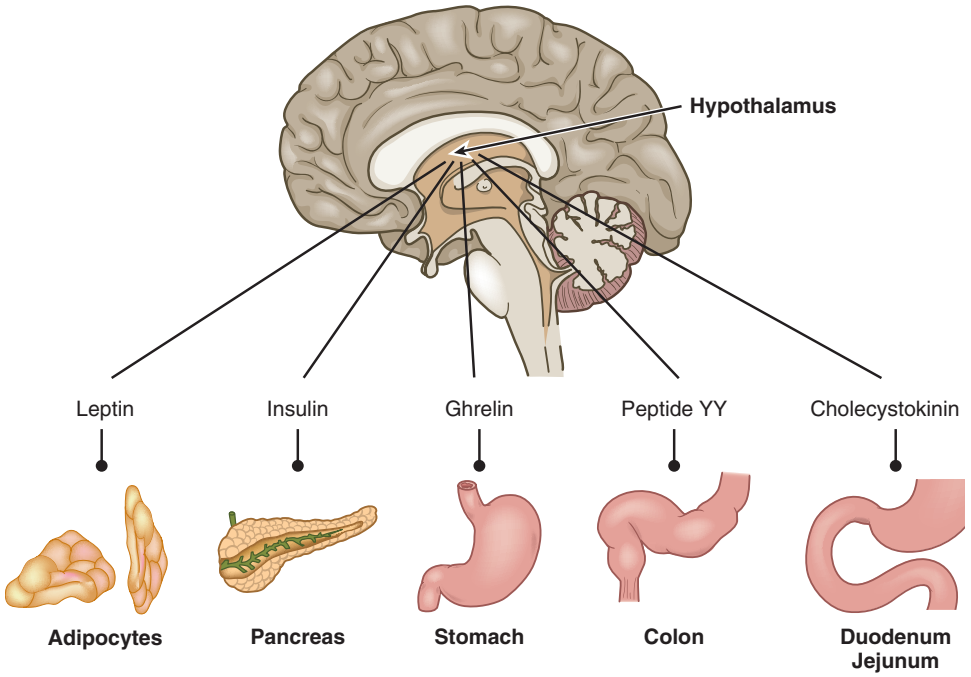

FIG. 41-3 Some of the common hormones and peptides that interact with the hypothalamus to control and influence eating patterns, metabolic activities, and digestion. Obesity disrupts this balance (see Table 41-3).

TABLE 41-3 HORMONES AND PEPTIDES IN OBESITY

Where Produced	Normal Function	Alteration in Obesity
Neuropeptide Y		
Hypothalamus	Stimulates appetite	Imbalance causes increased appetite.
Ghrelin		
Stomach (primarily)	Stimulates appetite ↑ After food deprivation ↓ In response to food in the stomach	Normal postprandial decline does not occur, which can lead to increased appetite and overeating.
Leptin		
Adipocytes	Suppresses appetite and hunger Regulates eating behavior	Obesity is associated with high levels. Leptin resistance develops; thus obese people may lose the effect of appetite suppression.
Insulin		
Pancreas	Decreases appetite	Increased insulin secretion which stimulates ↑ liver synthesis of triglycerides and ↓ HDL production.
Peptide YY		
Colon	Inhibits appetite by slowing GI motility and gastric emptying	Circulating levels are decreased. ↓ Release after eating.
Cholecystokinin		
Duodenum Jejunum	Inhibits gastric emptying and sends satiety signals to hypothalamus	Unknown role

HDL, High-density lipoprotein.

Physiologic Regulatory Mechanisms in Obesity. Research has focused on the physiologic regulatory processes that control eating behavior, energy metabolism, and body fat metabolism. Knowing how appetite is triggered and energy is expended provides important information for understanding obesity and specific targets for the development of drugs.

The hypothalamus, gut, and adipose tissue synthesize hormones and peptides that inhibit or stimulate the appetite (Fig. 41-3). The hypothalamus is a major site for regulating appetite. Neuropeptide Y, produced in the hypothalamus, is a powerful appetite stimulant. When it is imbalanced, it leads to overeating and obesity. Hormones and peptides produced in the gut and adipocyte cells affect the hypothalamus and have a critical role in appetite and energy balance (Table 41-3).

Leptin, secreted from adipocytes when they fill with fat, acts in the hypothalamus to suppress appetite, increase physical activity, and increase fat metabolism. A genetic deficiency of leptin causes extreme obesity. In obesity the level of leptin is actually increased, which has raised the question of whether obese people are insensitive to leptin.[2] Possible causes include failure to produce enough leptin receptors or production of receptors that are faulty.

Ghrelin, a gut hormone, regulates appetite through inhibition of leptin. In a fasting state, ghrelin is increased. Ghrelin acts in the hypothalamus by working on the reward system that triggers overeating. Ghrelin is thought to play a part in compulsive eating. In gastric bypass surgery, ghrelin is decreased significantly, which helps suppress appetite.

The two major consequences of obesity are due to the sheer increase in fat mass and the production of adipokines produced by fat cells. Adipocytes produce at least 100 different proteins. These proteins, secreted as enzymes, adipokines, growth factors, and hormones, contribute to the development of insulin resistance and atherosclerosis.

An increased release of cytokines from fat cells may disrupt immune factors, thus predisposing the person to certain cancers. Because visceral fat accumulation is associated with more alterations of these adipokines, people with abdominal obesity have more complications of obesity.[11]

Environmental Factors. Environmental factors play an important role in obesity. In today's culture, people have greater access to food, particularly prepackaged and fast foods, and soft drinks, which have poor nutritional quality. Portion size of meals has increased dramatically (Table 41-4). The Centers for Disease Control and Prevention has developed visual programs that demonstrate how portions have increased over time.[12] Underestimating portion sizes and therefore caloric intake is common. In addition, eating outside of the home interferes with the ability to control the quality and quantity of food.

Lack of physical exercise is another factor that contributes to weight gain and obesity. With increases in use of technology, labor-saving devices, and cars, Americans are expending less energy in their everyday lives. Elimination of physical education programs in schools, along with increased time spent playing video games and watching TV, has contributed to the increase in sedentary habits.

Socioeconomic status is a known risk factor for obesity in a variety of ways.[13] People with low incomes may attempt to stretch their food dollars by purchasing less expensive foods that often have poor nutritional quality with a greater caloric content. For example, people with low incomes are more likely to purchase pasta, bread, and canned fruit packed with sugar rather than chicken and fresh fruits and vegetables. Low-income residents may also live in environments that do not accommodate outdoor activities (e.g., safe playgrounds, walking tracks, tennis, swimming pools).

TABLE 41-4 PORTION SIZES: YESTERDAY VS TODAY

	25 Yr Ago	Today
Turkey sandwich	320 cal 	820 cal 
Bagel	3-in diameter, 140 cal 	6-in diameter, 350 cal 
Cheeseburger	333 cal 	590 cal 
Soda	6½ oz, 85 cal 	20 oz, 250 cal 

Psychosocial Factors. People use food for many reasons besides their nutritional value. Associations with food begin in childhood, such as the use of food for comfort or rewards. Furthermore, when overeating develops at an early age and continues into adulthood, one's ability to sense fullness *(satiety)* is compromised. Whether triggered by specific foods or by the wide variety of choices, some people consume more food than their bodies need. The lack of hunger that drives eating has been termed "mindless eating" and leads to consumption of unnecessary calories and increase in body weight.[13,14]

Finally, the social component of eating begins early in life when food is associated with pleasure and fun at such events as birthday parties, Thanksgiving, and religious holidays. All of these factors must be included when considering the etiology and treatment of obesity.

HEALTH RISKS ASSOCIATED WITH OBESITY

Hippocrates wrote that "corpulence is not only a disease itself, but the harbinger of others," thus recognizing that obesity has major adverse effects on health. Many problems occur in obese people at higher rates than people of normal weight (Fig. 41-4).

The medical cost of adult obesity in the United States is difficult to calculate, but estimates range from $147 billion to nearly $210 billion per year. The bulk of the spending is from treating obesity-related diseases such as diabetes. Obese people spend 42% more on health care costs than healthy-weight people.[4]

Mortality rates rise as obesity increases, especially when obesity is associated with visceral fat. For obese persons, mortality rates from all causes, especially from cardiovascular disease, are increased by 50% to 100% above those of persons with a normal BMI. Being overweight in midlife, once thought to have fewer health consequences than being obese, confers a 20% to 40% increase in mortality rate for both men and women.[11] In addition to these problems, obese patients have a reduced quality of life. Fortunately, most of these conditions can improve if an individual loses weight.

Cardiovascular Problems

Obesity is a significant risk factor for cardiovascular disease in both men and women.[11] Android obesity is the best predictor of these risks and is linked with increased low-density lipoproteins (LDLs), high triglycerides, and decreased high-density lipoproteins (HDLs). Obesity is also associated with hypertension, which can occur because of increased circulating blood volume, abnormal vasoconstriction, increased inflammation (damaging blood vessels), and increased risk of sleep apnea (raises blood pressure [BP]). Altered lipid metabolism and hypertension can increase the long-term risk of heart disease and stroke. Excess body fat can also lead to chronic inflammation throughout the body, especially in blood vessels, thus increasing the risk of heart disease.

Diabetes Mellitus

More than 80% of people with type 2 diabetes are obese or overweight.[4] Hyperinsulinemia and insulin resistance, common features of type 2 diabetes, are also found in obesity, especially when visceral fat is increased. Excess weight decreases the effectiveness of insulin. When insulin does not work effectively, too much glucose stays in the bloodstream. Thus more insulin is made to compensate. Pancreatic β cells (cells that make insulin)

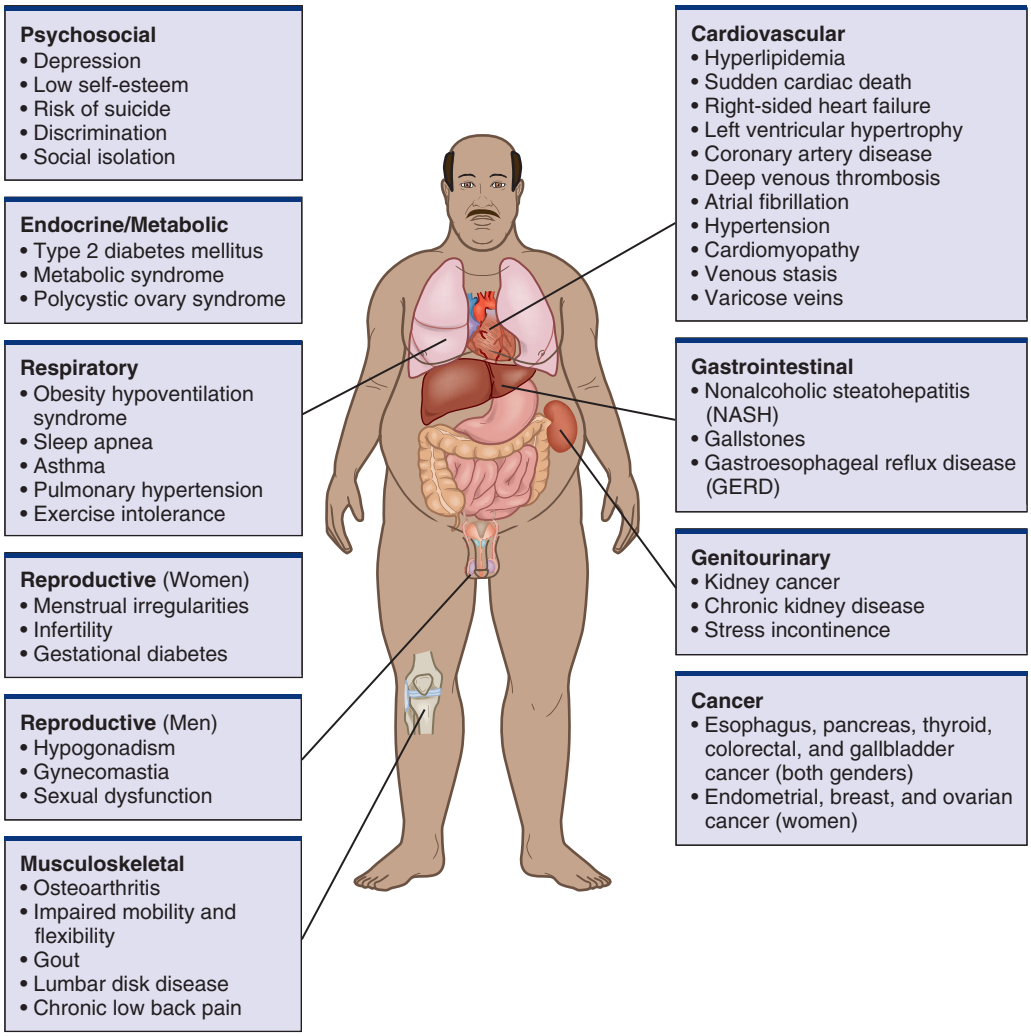

FIG. 41-4 Health risks associated with obesity.

may get overworked and become worn out. Over time, the pancreas is no longer able to keep blood glucose in normal range. It appears that adiponectin, a peptide that increases insulin sensitivity, is decreased in obese people.

Obesity is a major risk factor for development of type 2 diabetes. Furthermore, obesity complicates the management of type 2 diabetes by increasing insulin resistance and glucose intolerance, which makes drug treatment for diabetes less effective. A weight reduction of 7% can decrease the risk of diabetes by 58%.[15]

Gastrointestinal and Liver Problems

Gastroesophageal reflux disease (GERD) and gallstones are more prevalent in obese people. Gallstones occur due to supersaturation of the bile with cholesterol. Nonalcoholic steatohepatitis (NASH) is a condition in which lipids are deposited in the liver, resulting in a fatty liver. NASH is associated with elevated hepatic glucose production. NASH can eventually progress to cirrhosis and can be fatal. Weight loss can improve NASH.

Respiratory and Sleep Problems

The increased fat mass associated with obesity may lead to sleep apnea and obesity hypoventilation syndrome. The increased distribution of fat around the diaphragm causes a reduced chest wall compliance, increased work of breathing, and decreased total lung capacity and functional residual capacity. Sleep apnea results from increased fat around the neck, leading to snoring and hypoventilation while sleeping. Weight loss can bring substantial improvement in lung function.

Poor sleep and sleep deprivation may increase appetite. Sleep deprivation has been associated with obesity. Building up a sleep debt over a matter of days can impair metabolism and disrupt hormone levels. The level of leptin falls in people who are sleep deprived, thus promoting appetite.

Musculoskeletal Problems

Obesity is associated with an increased incidence of osteoarthritis because of the stress put on weight-bearing joints, especially the knees and hips. Increased body fat also triggers inflammatory mediators and contributes to deterioration of cartilage. Hyperuricemia and gout are often found in people who are obese and in those who have metabolic syndrome (discussed later in this chapter).

Cancer

Obesity is one of the most important known preventable causes of cancer. About 20% of cancers in women and 15% in men are attributable to obesity.[16] The types of cancer most strongly

linked to excess body fat are breast, endometrial, kidney, colorectal, pancreatic, esophageal, and gallbladder cancer.

The underlying mechanisms linking obesity and cancer remain unclear. Breast and endometrial cancer may be due to the increased estrogen levels (estrogen is stored in fat cells) associated with obesity in postmenopausal women. Colorectal cancer has been linked to hyperinsulinemia, and esophageal cancer may be secondary to acid reflux caused by abdominal obesity. Several hormones and factors often present in obese states have been identified as potentiating the risk for cancer. For example insulin, which is a powerful cellular growth factor, is increased in obesity. The resulting hyperinsulinemia may affect cancer cells.

Adipokines (from fat cells) may stimulate or inhibit cell growth. For example, leptin, which is increased in obese people, promotes cell proliferation.

Metabolic Syndrome

Metabolic syndrome is one of the fastest-growing obesity health concerns. It is discussed later in this chapter on p. 921.

Psychosocial Problems

The consequences of obesity extend beyond the physical changes. Stigmatization of obese people, and in some cases discrimination, occurs in three important areas of living: employment, education, and health care. The social stigma associated with obesity has an emotional toll on a person's psychologic well-being. Many obese persons suffer low self-esteem, withdraw from social interaction, and experience major depression.

NURSING AND COLLABORATIVE MANAGEMENT OBESITY

NURSING ASSESSMENT

The first step in the treatment of obesity is to determine whether any physical conditions are present that may be causing or contributing to obesity. This requires a thorough history and physical examination.

Table 41-5 lists information that can assist you in understanding an obese patient and provides a basis for intervention. When assessing an individual who is overweight or obese, be sensitive and nonjudgmental in asking specific and leading questions about weight, diet, and exercise (Table 41-6). In doing so, you can often obtain information that the patient might have withheld out of embarrassment or shyness. Patients need to understand the rationale for questions asked about weight or dietary habits, and you must be ready to respond to their concerns.

When obtaining the history, explore genetic and endocrine factors such as hypothyroidism, hypothalamic tumors, Cushing syndrome, hypogonadism in men, and polycystic ovary syndrome in women. Laboratory tests of liver function and thyroid function, a fasting glucose level, and a lipid panel (triglyceride level, LDL and HDL cholesterol levels) assist in evaluating the cause and effects of obesity. When no organic cause (e.g., hypothyroidism) is associated with obesity, the disorder should be considered a chronic, complex illness.

As part of the initial nursing history and physical examination, examine each body system with particular attention to the organ system in which the patient has expressed a problem or concern. Measurements used with the obese person may include skinfold thickness, waist circumference, height (without shoes), weight (obtain in a private location and in a gown if possible), and BMI. Provide specific documentation on these areas. Also assess for any co-morbid diseases associated with obesity (e.g., hypertension, sleep apnea), since these conditions require special treatment.

TABLE 41-5 NURSING ASSESSMENT

Obese Patient

Subjective Data

Important Health Information

Past health history: Time of obesity onset; diseases related to metabolism and obesity, such as hypertension, cardiovascular problems, stroke, cancer, chronic joint pain, respiratory problems, diabetes mellitus, cholelithiasis, metabolic syndrome

Medications: Thyroid preparations, diet pills, herbal products

Surgery or other treatments: Prior weight-reduction procedures (bariatric surgery)

Functional Health Patterns

Health perception–health management: Family history of obesity; perception of problem; methods of weight loss attempted

Nutritional-metabolic: Amount and frequency of eating; overeating in response to boredom, stress, specific times, or activities; history of weight gain and loss

Elimination: Constipation

Activity-exercise: Typical physical activity; drowsiness, somnolence; dyspnea on exertion, orthopnea, paroxysmal nocturnal dyspnea

Sleep-rest: Sleep apnea, use of continuous positive airway pressure (CPAP)

Cognitive-perceptual: Feelings of rejection, depression, isolation, guilt, or shame; meaning or value of food; adherence to prescribed reducing diets, degree of long-term commitment to a weight loss program

Role-relationship: Change in financial status or family relationships; personal, social, and financial resources to support a reducing diet

Sexuality-reproductive: Menstrual irregularity, heavy menstrual flow in women, birth control practices, infertility; effect of obesity on sexual activity and attractiveness to significant other

Objective Data

General

Body mass index ≥30 kg/m^2; waist circumference: woman >35 in (89 cm), man >40 in (102 cm)

Respiratory

Increased work of breathing; wheezing; rapid, shallow breathing

Cardiovascular

Hypertension, tachycardia, dysrhythmias

Musculoskeletal

Decreased joint mobility and flexibility; knee, hip, and low back pain

Reproductive

Gynecomastia and hypogonadism in men

Possible Findings

Elevated serum glucose, cholesterol, triglycerides; chest x-ray demonstrating enlarged heart; electrocardiogram showing dysrhythmia; abnormal liver function tests

PLANNING

The overall goals are that the obese patient will (1) modify eating patterns, (2) participate in a regular physical activity program, (3) achieve and maintain weight loss to a specified level, and (4) minimize or prevent health problems related to obesity.

TABLE 41-6 ASSESSING PATIENTS WITH OBESITY

When assessing patients with obesity and before selecting a weight loss strategy, ask the following questions.

- What is your history with weight gain and weight loss?
- What is your motivation for losing weight?
- Would you like to manage your weight differently? If so, how?
- What do you think contributes to your weight?
- What sort of barriers do you think impede your weight loss efforts?
- Are there any major stresses that will make it difficult to focus on weight control?
- What does food mean to you? How do you use food (e.g., to relieve stress, provide comfort)?
- Are other family members overweight?
- How much time can you devote to exercise on a daily or weekly basis?
- How has your health been affected by your body weight?
- What type of support do you have from family and/or friends for losing weight?

TABLE 41-7 COLLABORATIVE CARE

Obesity

Diagnostic

- History and physical examination
- BMI
- Waist-to-hip ratio

Collaborative Therapy

- Nutritional therapy
- Exercise
- Behavior modification
- Support groups
- Drug therapy
  - Appetite-suppressing drugs
  - Nutrient absorption–blocking drugs (orlistat [Xenical])
  - Serotonin agonists (lorcaserin [Belviq])
  - phentermine and topiramate (Qsymia)
- Surgical therapy (see Table 41-9)

BMI, Body mass index.

NURSING IMPLEMENTATION

Obesity is one of the most challenging health crises in the United States. It is a chronic disease, much like hypertension and diabetes. Although obese people can lose weight, they often tend to regain weight. For most patients, lifelong management is indicated.

Together with other members of the health care team, you have a major role in planning for and managing the care of an obese patient. First, examine your own personal beliefs and any potential biases related to obesity. If you associate obesity with a lack of willpower and with overindulgence, the patient can experience shame in a setting that claims to be a caring one. You are in a pivotal position to help overweight and obese individuals. Interventions include helping obese patients explore and deal with their negative experiences and educating other health professionals about stigma and biases experienced by obese patients.

Although health care for obese people has inherently greater demands, health care providers often fail to address these needs, and obese people underutilize health care opportunities available to them. Health care providers are often reluctant to counsel patients about obesity for a variety of reasons, including (1) time constraints during appointments make it difficult, (2) weight management may be viewed as professionally unrewarding, (3) reimbursement for weight management services is difficult to obtain, and (4) many providers do not feel knowledgeable about giving weight loss advice.

Despite the known benefits of weight loss, it is a difficult process for most individuals. Obesity treatment begins with patients understanding their weight history and deciding on a plan that is best for them. In general, the average weight loss program (except for bariatric surgery) results in a 10% reduction of body weight. This average reduction should not be considered a failure, since it is associated with significant health benefits.

Exploring an individual's motivation for weight loss is essential for overall success. Using principles from motivational interviewing (discussed in Chapter 11 on p. 157), you can help patients understand their desire to lose weight and gain confidence in achieving weight loss.[17]

Focusing on the reasons for wanting to lose weight may help patients develop strategies for a weight loss program. Any supervised plan of care must be directed at two different processes: (1) successful weight loss, which requires a short-term energy deficit; and (2) successful weight control, which requires long-term behavior changes.[18]

A multifaceted approach needs to be used, including nutritional therapy, exercise, behavior modification, and for some, medication or surgical intervention (Table 41-7). Focusing on more than one aspect provides for more effective weight loss and weight control efforts. While doing patient teaching, stress healthy eating habits and adequate physical activity as lifestyle patterns to develop and maintain.

A number of smart phone applications are now available to help patients track eating patterns, calories, and exercise. These tracking systems may provide a patient with immediate access to nutritional information for better dietary decision making.

Even with a comprehensive action plan, there is a high rate of weight regain. This is discouraging when one considers the amount of time, effort, and money expended in attempts to lose weight. For successful management of obesity, it is beneficial to view obesity as a chronic life-long condition that necessitates day-to-day attention.

NUTRITIONAL THERAPY. Restricting dietary intake so that it is below energy requirements is a cornerstone for any weight loss or maintenance program. A good weight loss plan should contain foods from the basic food groups (MyPlate is presented in Fig. 40-1 and Table 40-1). A dietary reduction of at least 500 to 1000 cal/day is recommended for an expected weight loss of 1 to 2 lb/wk.[18] (Table 41-8 presents an example of a 1200-calorie diet.)

A supervised diet plan may be prescribed limiting calories to a total of 800 or less calories per day, but this is not sustainable on a long-term basis. Persons on low-calorie and very-low-calorie diets need frequent professional monitoring because the severe energy restriction places them at risk for multiple nutrient deficiencies.

In general, it is best to recommend a diet that includes adequate amounts of fruits and vegetables, provides enough bulk to prevent constipation, and meets daily vitamin A and vitamin C requirements. Lean meat, fish, and eggs provide sufficient protein and the B-complex vitamins.

It is rare to find an overweight person who has not at some time attempted to lose weight. Some people met with limited

TABLE 41-8 NUTRITIONAL THERAPY

1200-Calorie–Restricted Weight-Reduction Diet*

General Principles

1. Eat regularly. Do not skip meals.
2. Measure foods to determine the correct portion size.
3. Avoid concentrated sweets, such as sugar, candy, honey, pies, cakes, cookies, and regular sodas.
4. Reduce fat intake by baking, broiling, or steaming foods.
5. Maintain a regular exercise program for successful weight loss.

Meal	Exchanges	Menu Plan†
Breakfast	1 meat	1 hard-boiled egg
	2 bread	1 slice toast
		¾ cup dry cereal (unsweetened)
	1 fruit	½ small banana
	1 fat	1 tsp margarine
	1 dairy‡	1 cup low-fat milk
	Beverage	Coffee
Lunch	2 meat	Cheese enchiladas (made with 2 oz cheese, two corn tortillas, lettuce, chili sauce)
	2 bread	
	Vegetable	
	1 fruit	Fresh grapes (12)
	Beverage	Diet soda
Dinner	2 meat	2 oz baked chicken
	1 bread	Corn on the cob with 1 tsp margarine
	Vegetable	Tossed salad and 1 tbs salad dressing
	1 fruit	¾ cup strawberries
	1 milk	1 cup low-fat milk

*For 1000 cal, omit 1 fruit exchange and change low-fat milk to skim milk. For 1500 cal, add 1 meat exchange, 1 fruit exchange, and 2 fat exchanges; change low-fat milk to whole milk. For 1800 cal, add 2 bread exchanges, 3 meat exchanges, 3 fat exchanges, and 1 fruit exchange; change low-fat milk to whole milk.
†Additional sample meal plans are presented in eTable 41-2 available on the website for this chapter.
‡One extra fat exchange allowed for each cup of 2% low-fat milk; 2 extra fat exchanges allowed for each cup of skim milk.

and temporary success, and others have met only with failure. Many individuals attempt weight loss by trying one of the many fad diets that offer the enticement of quick weight loss with little effort (see eTable 41-1 on the website). Often these quick weight-reduction diets (found in the popular media) advocate the elimination of one category of foods (e.g., carbohydrates). Therefore these should be discouraged. Low-carbohydrate diets do produce a rapid weight loss, but reduce the opportunity to get adequate amounts of fiber, vitamins, and minerals. These restrictive diets are difficult to maintain in the long term. It is best to recommend a dietary approach in which calorie restriction includes all food groups. Patients will find it easier to incorporate such a change into their lifestyle and not become as bored with their food options.

The weight loss associated with fad diets is generally short lived. The MyPlate guidelines have longer-lasting results. However, the degree of weight loss strongly depends on the patient's ability to adhere to the diet. The more restrictive the regimen, the greater the demand for intense discipline in the face of an intense desire to eat foods not allowed on the diet.[19]

The degree of success of any reducing diet depends in part on the amount of weight to be lost. A moderately obese person will obviously attain his or her goal more easily than a severely obese person. Because men have a higher percentage of lean body mass, they are often able to lose weight more quickly than women. Women have a higher percentage of body fat, which is metabolically less active than muscle tissue. Postmenopausal women are particularly prone to weight gain, including increased abdominal fat.

Motivation is an essential ingredient for successful weight loss. The obese patient must recognize the advantages of weight loss and weight control. You can assist by helping the patient track eating patterns with a diet diary. Through a frank discussion of eating patterns, the patient often realizes that eating is "mindless" and the result of bad habits picked up over time. These eating behaviors must be changed, or any weight loss will only be temporary.

Setting a realistic and healthy goal, such as losing 1 to 2 lb/wk, should be mutually agreed on at the beginning of counseling. Trying to lose too much too fast usually results in a sense of frustration and failure for the patient. You can help patients understand that losing large amounts of weight in a short period causes skin and underlying tissue to lose elasticity and tone. Slower weight loss offers better cosmetic results.

Inevitably, the patient reaches plateau periods during which no weight is lost. These plateaus may last from several days to several weeks. Remind the patient that plateaus are normal occurrences during weight reduction. A weekly check of body weight is a good method of monitoring progress. Daily weighing is not recommended because of the frequent fluctuations resulting from retained water (including urine) and elimination of feces. Instruct the patient to record the weight at the same time of the day, wearing the same type of clothing.

Experts disagree on the number of meals to be eaten when a person is on a diet. Some nutritionists advocate several small meals per day because the body's metabolic rate is temporarily increased immediately after eating. However, when eating several small meals a day, patients may consume more calories unless they carefully adhere to portion sizes and total daily calorie allotment.

When a person first starts a weight-reduction program, food portion sizes need to be carefully determined to stay within the dietary guidelines. Portion sizes over the past 20 years have increased considerably[12] (see Table 41-4). Food portions can be weighed using a scale, or everyday objects can be used as a visual cue to determine portion sizes. The size of a woman's fist or a baseball is equivalent to a serving of vegetables or fruit. A serving of meat is about the size of a person's palm or a deck of cards. A serving of cheese is about the size of a thumb or six dice. A test on portion sizes is available at *http://hin.nhlbi.nih.gov/portion/index.htm*.

Another aspect of the American diet that needs to be considered is which foods contribute the most calories—animal sources, fruits, grains, or vegetables. Two thirds or more of an individual's diet should be plant-source foods, and the other one third or less should be from animal protein. Being aware of personal consumption habits and striving for the two-thirds to one-third ratio is a simple goal that can be achieved without weighing and measuring foods at every meal. Once this ratio has been adopted into the patient's meal planning, portions can gradually be reduced as activity levels are gradually increased to achieve healthy weight loss. The recommended portion size of animal protein is 3 oz. The standard size for chopped vegetables is ½ cup, according to MyPlate guidelines (see Table 40-1).

A list of healthy or low-calorie foods serves as a good reference and permits an occasional meal to be eaten at a restaurant. Furthermore, the patient who carefully follows the prescribed diet may not need to take vitamin supplements. Encourage the appropriate fluid intake in the form of water. Alcoholic and

sugary beverages should be limited or avoided, since they increase caloric intake and are low in nutritional value.

EXERCISE. Exercise is an essential part of a weight control program. Patients should exercise daily, preferably 30 minutes to an hour. There is no evidence that increased activity promotes an increase in appetite or leads to dietary excess. In fact, exercise frequently has the opposite effect. The addition of exercise produces more weight loss than does dieting alone and has a favorable effect on body fat distribution. With regular exercise, WHR is reduced. Finally, exercise is especially important in maintaining weight loss.

When large muscles are involved in the exercise program, a primary benefit is cardiovascular conditioning. Overweight men and women who are active and fit have lower rates of morbidity and mortality than overweight persons who are sedentary and unfit. Therefore exercise is of benefit to overweight persons even if it does not make them lean. Many psychologic benefits can be derived from an increased physical activity program. Exercise decreases tension and stress, promotes better-quality sleep and rest, increases stamina and energy, improves self-concept and self-confidence, improves attitudes, and increases optimism about the future.[18]

Explore with the patient possible ways to incorporate exercise in daily routines. It may be as simple as parking farther from their place of employment or taking the stairs versus an elevator. Encourage individuals to wear a pedometer to track their activity with a goal of 10,000 steps a day. However, success may be walking one third of the recommended steps with incremental increases over time. Although joining a health club can be one way of getting exercise, it is not necessary. Patients can walk, swim, and cycle, all of which have long-term benefits. Stress to patients that engaging in weekend exercise only or in spurts of strenuous activity is not advantageous and can actually be dangerous.

BEHAVIOR MODIFICATION. The assumption behind behavior modification is twofold: (1) obesity is a learned disorder caused by overeating and (2) often the critical difference between an obese person and a person of normal weight is the cues that regulate eating behavior. Therefore most behavior-modification programs deemphasize the diet and focus on how and when to eat.

Teach people to restrict their eating to designated meals and to increase the amount of physical activity in their lives. Persons who participate in a behavioral therapy program are more successful in maintaining their losses over an extended time than those who do not participate in such training.

Various behavioral techniques for patients engaged in a weight loss program include (1) self-monitoring, (2) stimulus control, and (3) rewards. *Self-monitoring* may involve keeping a record of the type and time food was consumed and how the person was feeling when eating. *Stimulus control* is aimed at separating events that trigger eating from the act of eating. *Rewards* may be used as incentives for weight loss. Short- and long-term goals are useful benchmarks for earning rewards. It is important that the reward for a specified weight loss not be associated with food, such as dinner out or a favorite treat. Reward items do not have to have a monetary component. For example, time for a hot bath or an hour of pleasure reading would be an enjoyable reward for many people.

SUPPORT GROUPS. People who are on a weight management plan are often encouraged to join a group where others are also trying to modify their eating habits. Many self-help groups are available that offer support and information on dieting tips. For example, Take Off Pounds Sensibly (TOPS) *(www.tops.org)* is the oldest nonprofit organization of this type. Behavior modification is an integral part of the program, along with nutrition education. Weight Watchers International, Inc. *(www.weightwatchers.com)* is probably the most successful commercial weight-reduction enterprise. Weight Watchers offers a food plan that is nutritionally balanced and practical to follow. Group leaders, all of whom have successfully lost weight with Weight Watchers, teach members various behavior-modification techniques.

Commercial weight-reduction centers have proliferated across the nation. Many of these programs are staffed by nurses and dietitians. An initial physical examination by a health care provider is required before a candidate is accepted for weight reduction. These weight-reduction centers are cost prohibitive for those with limited financial resources. Many of these programs also offer special prepackaged foods and supplements that must be purchased as part of the weight-reduction plan. Only these prescribed foods and drinks are to be consumed until an agreed-on amount of weight is lost. The patient is encouraged to buy the same type of foods for the maintenance phase of the program, lasting from 6 months to 1 year. Behavior-modification training is incorporated in these programs as well. Individuals must learn how to adjust their diet once they are no longer using the commercial products. This can be challenging for many, and the weight lost may be regained once the restricted food program is completed.

In recent years a number of employers have begun weight loss programs at the workplace. The rationale for such programs is that better health repays the cost of the programs through improved work performance, decreased absenteeism, less hospitalization, and lower insurance costs. Such programs have been well accepted by both employees and employers.

DRUG THERAPY

Drugs should never be used alone. Rather, they should be part of a comprehensive weight-reduction program that includes reduced-calorie diet, exercise, and behavior modification. Drugs should be reserved for adults with a BMI of 30 kg/m^2 or greater (obese), or adults with a BMI of 27 kg/m^2 or greater (overweight) who have at least one weight-related condition such as hypertension, type 2 diabetes, or dyslipidemia.

Appetite-Suppressing Drugs

The sympathomimetic amines suppress appetite by increasing the availability of norepinephrine in the brain, thus stimulating the central nervous system. The sympathomimetics fall into two groups: amphetamines and nonamphetamines. The amphetamines have a much higher abuse potential than the nonamphetamines. Amphetamines are not recommended nor are they approved by the U.S. Food and Drug Administration (FDA) for either short- or long-term weight loss.

Nonamphetamines are not usually recommended for weight loss because of the potential for abuse. If used, these drugs should only be used short term (for 3 months or less). Nonamphetamines include phentermine (Adipex-P, Fastin, Ionamin), diethylpropion (Tenuate), phendimetrazine (Bontril), and benzphetamine (Didrex). Adverse effects of these drugs include palpitations, tachycardia, overstimulation, restlessness, dizziness, insomnia, weakness, and fatigue.

Nutrient Absorption–Blocking Drugs

Orlistat (Xenical) works by blocking fat breakdown and absorption in the intestine. It inhibits the action of intestinal lipases, resulting in undigested fat excreted in the feces. Some fat-soluble vitamin levels may also decrease and may need to be supplemented. Allī, a low-dose form of orlistat, is available for over-the-counter use.

Orlistat is associated with leakage of stool, flatulence, diarrhea, and abdominal bloating, which is accentuated if a high-fat diet is consumed. These side effects limit its acceptance as a weight loss tool. Severe liver injury has been reported in patients using orlistat.[20]

Serotonin Agonist

Lorcaserin (Belviq) is a selective serotonin (5-HT) agonist that suppresses appetite and creates a sense of satiety. Lorcaserin works by activating the serotonin receptor in the brain. Activation of this receptor may help a person eat less and feel full after eating smaller amounts of food. The most common side effects are headache, dizziness, fatigue, nausea, dry mouth, and constipation.

Phentermine and Topiramate (Qsymia)

Qsymia is a combination of two drugs, phentermine and topiramate. Phentermine is a sympathomimetic agent already approved for short-term management of obesity. Topiramate is currently approved for seizure disorders and prophylaxis of migraine. In overweight patients, phentermine suppresses appetite, and topiramate induces a sense of satiety. Qsymia must not be used in patients with glaucoma or hyperthyroidism. Qsymia can increase heart rate, and its effect on the heart rate in patients at high risk for heart attack or stroke is not known.

Nursing Interventions Related to Drug Therapy

Drugs will not cure obesity, and individuals must understand that without substantial changes in food intake and increased physical activity, they will gain weight when drug therapy is stopped. As with any drug treatment, there are side effects. Careful evaluation for other medical conditions can help determine which drugs, if any, would be advisable for a given patient.

Your role related to drug therapy is to teach the patient about proper administration, side effects, and how the drugs fit into the overall weight loss plan. The modification of dosage without consultation with the health care provider can have detrimental effects. Emphasize that diet and exercise regimens are the cornerstones of permanent weight loss. Finally, discourage the purchase of over-the-counter diet aids except for Allī.

SURGICAL THERAPY

Bariatric surgery has become a viable and popular option for treating obesity.[21] Surgery is currently the only treatment that has been found to have a successful and lasting impact for sustained weight loss for severely obese individuals.[22]

The majority of people who undergo bariatric surgery successfully improve their overall quality of life. In addition to losing weight, patients often experience resolution of comorbidities such as diabetes. Although overall mortality is very low, a number of complications can arise from surgery, and the option to have surgery must be carefully considered.

Criteria guidelines for bariatric surgery include having a BMI of 40 kg/m^2 or a BMI of 35 kg/m^2 with one or more severe obesity-related medical complications (e.g., hypertension, type 2 diabetes mellitus, heart failure, sleep apnea). Many insurance carriers do not cover the cost of bariatric surgery. If they do consider reimbursing for the surgery, most of them require documentation of a medically supervised weight loss program for approximately 6 months.[23]

Before being considered candidates for surgery, patients must be screened for psychologic, physical, and behavioral conditions that have been associated with poor surgical outcomes. These include untreated depression, binge eating disorders, and drug and alcohol abuse that may interfere with a commitment to lifelong behavioral changes. Other contraindications to surgery include illnesses that are known to reduce life expectancy and are not likely to be improved with weight reduction. These conditions include advanced cancer; end-stage kidney, liver, and cardiopulmonary disease; severe coagulopathy; or inability to comply with nutritional recommendations.[24]

Bariatric surgeries fall into one of three broad categories: restrictive, malabsorptive, or a combination of malabsorptive and restrictive (Table 41-9 and Fig. 41-5). In *restrictive procedures* the stomach is reduced in size (less food eaten), and in *malabsorptive procedures* the length of the small intestine is decreased (less food absorbed).[21] The majority of procedures are performed laparoscopically, thus decreasing postoperative recuperation as compared to an open procedure. With laparoscopy, patients have fewer wound infections, shorter hospital stays, and a faster recovery period.[23]

Restrictive Surgeries

Restrictive bariatric surgery reduces either the size of the stomach, which causes the patient to feel full more quickly, or the amount allowed to enter the stomach. In these surgeries, digestion is not altered so the risk of anemia or cobalamin deficiency is low. The most common restrictive surgeries include adjustable gastric banding and vertical sleeve gastrectomy.[24]

Adjustable Gastric Banding. Laparoscopic *adjustable gastric banding* (AGB), the most common restrictive procedure done, involves limiting the stomach size with an inflatable band placed around the fundus of the stomach (Fig. 41-5, *A*). This restrictive procedure can be done using a Lap-Band or Realize Band system. The band is connected to a subcutaneous port and can be inflated or deflated (by fluid injection in the health care provider's office) to change the stoma size to meet the patient's needs as weight is lost. The restrictive effect of the band creates a sense of fullness as the upper portion of the stomach now accommodates less than the average stomach. The band then causes a delay in stomach emptying, providing patients with further satiety.

The procedure can be either modified or reversed at a later date if necessary. AGB is the preferred option for patients who are surgical risks because it is a less invasive approach.

Vertical Sleeve Gastrectomy. In the vertical sleeve gastrectomy, about 85% of the stomach is removed, leaving a sleeve-shaped stomach (Fig. 41-5, *B*). Although the stomach is drastically reduced in size, its function is preserved. The procedure is not reversible. The removal of the majority of the stomach also results in the elimination of hormones produced in the stomach that stimulate hunger, such as ghrelin.

Combination of Restrictive and Malabsorptive Surgery

Roux-en-Y Gastric Bypass. The Roux-en-Y gastric bypass (RYGB) procedure is a combination of restrictive and malab-

TABLE 41-9 SURGICAL INTERVENTIONS FOR OBESITY*

Procedure	Anatomic Changes	Advantages	Complications
Restrictive Surgery			
Adjustable gastric banding (AGB) (Lap-Band, Realize Band)	Band encircles the stomach, creating a stoma and a gastric pouch with about 30 mL capacity	• Food digestion occurs through normal process • Band can be adjusted to ↑ or ↓ restriction • Surgery can be reversed • Absence of dumping syndrome • Lack of malabsorption	• Low complication rate • Some nausea and vomiting initially • Problems with adjustment device • Band may slip or erode into stomach wall • Gastric perforation
Vertical sleeve gastrectomy	About 85% of stomach removed, leaving a sleeve-shaped stomach with 60-150 mL capacity	• Function of stomach preserved • No bypass of intestine • Avoids complications of obstruction, anemia, vitamin deficiencies	• Weight loss may be limited • Leakage related to stapling
Vertical banded gastroplasty (VBG)	Band placed around stomach, and staples used above band to create a small gastric pouch	• No surgical anastomosis • More normal anatomy and physiology maintained • Lower risk of infection	• High complication rate • Slow weight loss • Rupture of staple line • Dilated pouch • Dumping syndrome (nausea, vomiting, and/or diarrhea related to ingestion of sweets, high-calorie liquids, or dairy products)
Malabsorptive Surgery			
Biliopancreatic diversion (BPD) with or without duodenal switch	70% of the stomach removed horizontally Anastomosis between the stomach and the intestine Decreases the amount of small intestine available for nutrient absorption Duodenal switch cuts the stomach vertically and is shaped like a tube	• Increased amount of food intake • Less food intolerance • Greater long-term weight loss • Rapid weight loss	• Abdominal bloating, diarrhea, and foul-smelling gas (steatorrhea) • Three or four loose bowel movements a day • Malabsorption of fat-soluble vitamins • Iron deficiency • Protein-calorie malnutrition • Dumping syndrome (with duodenal switch, last two problems are less common)
Combination of Restrictive and Malabsorptive Surgery			
Roux-en-Y gastric bypass (RYGB)	Restrictive surgery on stomach creating pouch Small gastric pouch connected to jejunum Remaining stomach and first segment of small intestine are bypassed	• Better weight loss results than with gastric restrictive procedures • Lower incidence of malnutrition and diarrhea • Rapid improvement of weight-related co-morbidities	• Leak at site of anastomosis • Anemia: iron deficiency, cobalamin deficiency, folic acid deficiency • Calcium deficiency • Dumping syndrome

*See Fig. 41-5.

sorptive surgery. This surgical procedure is the most common bariatric procedure performed in the United States and is considered the gold standard among bariatric procedures.

This procedure, which is irreversible, involves creating a small gastric pouch and attaching it directly to the small intestine using a Y-shaped limb of the small bowel. After the procedure, food bypasses 90% of the stomach, the duodenum, and a small segment of jejunum.

Overall, it has low complication rates, has excellent patient tolerance, and sustains long-term weight loss. Outcomes include improved glucose control with improvement or reversal of diabetes, normalization of BP, decreased total cholesterol and triglycerides, decreased GERD, and decreased sleep apnea.[25]

A complication of the RYGB is *dumping syndrome,* in which gastric contents empty too rapidly into the small intestine, overwhelming its ability to digest nutrients. Symptoms can include vomiting, nausea, weakness, sweating, faintness, and, on occasion, diarrhea. Patients are discouraged from eating sugary foods after surgery to avoid dumping syndrome.[25] Because sections of the small intestine are bypassed, poor absorption of iron can cause iron-deficiency anemia. Patients need to take a multivitamin with iron and calcium supplements. Chronic anemia caused by cobalamin deficiency may also occur. This problem can usually be managed with parenteral or intranasal cobalamin.

Cosmetic Surgeries to Reduce Fatty Tissue and Skinfolds

Lipectomy. **Lipectomy** (adipectomy) is performed to remove unsightly flabby folds of adipose tissue (Fig. 41-6). In some patients, up to 15% of the total fat cells can be removed from the breasts, abdomen, and lumbar and femoral areas. There is no evidence that a regeneration of adipose tissue occurs at the surgical sites. However, emphasize to the patient that surgical removal does not prevent obesity from recurring, especially if lifetime eating habits remain the same. Although body image and self-esteem may be enhanced by such procedures, these operations are not without complications. The dangerous effects of anesthesia and the potential for poor wound healing in the obese patient cannot be overemphasized.

Liposuction. Another cosmetic surgical procedure is liposuction, or suction-assisted lipectomy. It is used for cosmetic purposes and not for weight reduction. This surgical intervention helps improve facial appearance or body contours. A good candidate for this type of surgery is a person who has achieved weight reduction but who has excess fat under the chin, along the jaw line, in the nasolabial folds, over the abdomen, or

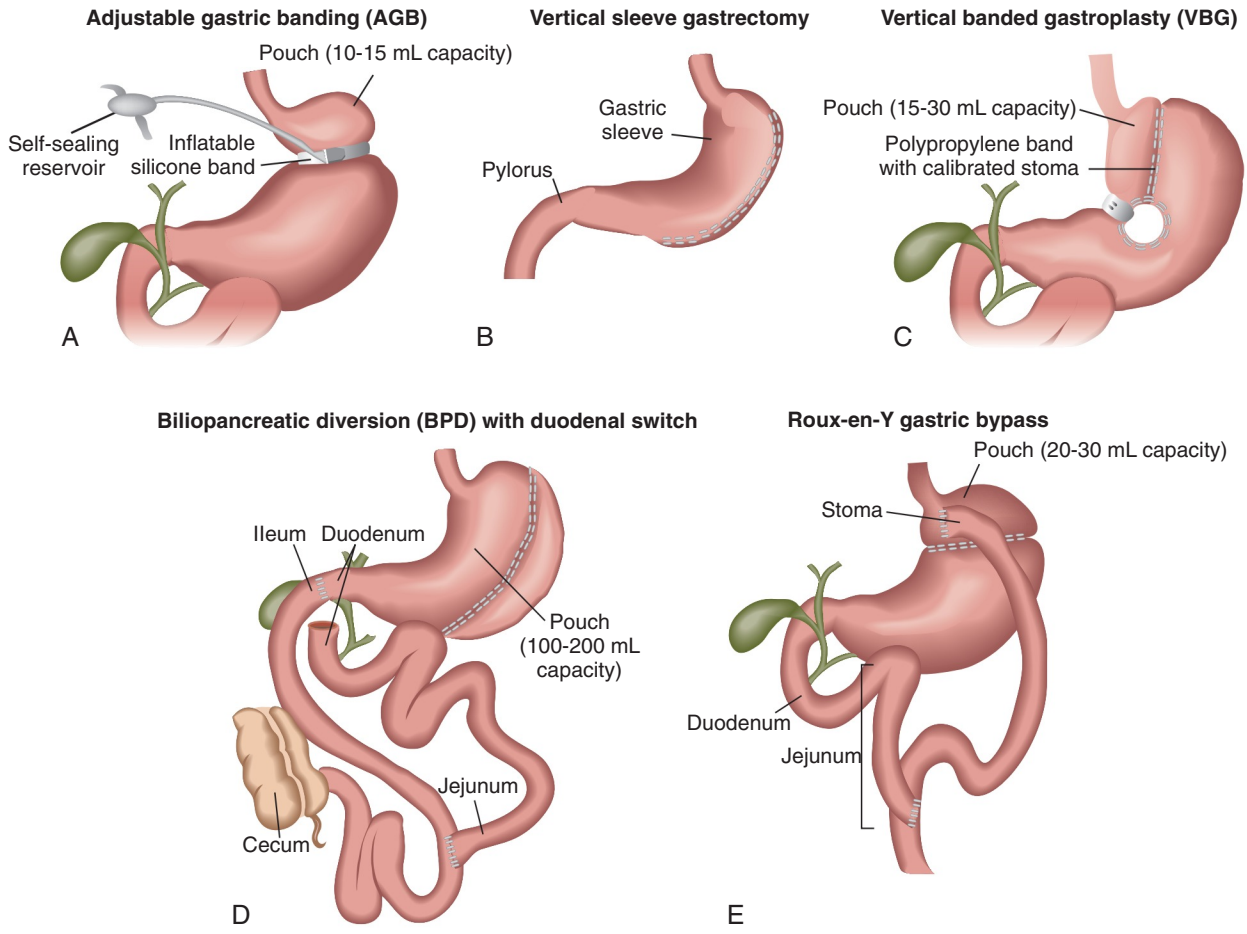

FIG. 41-5 Bariatric surgical procedures. **A,** Adjustable gastric banding (AGB) uses a band to create a gastric pouch. **B,** Vertical sleeve gastrectomy involves creating a sleeve-shaped stomach by removing about 80% of the stomach. **C,** Vertical banded gastroplasty (VBG) involves creating a small gastric pouch. **D,** Biliopancreatic diversion (BPD) with duodenal switch procedure creates an anastomosis between the stomach and the intestine. **E,** Roux-en-Y gastric bypass procedure involves constructing a gastric pouch whose outlet is a Y-shaped limb of small intestine.

FIG. 41-6 A, Preoperative view of a 37-year-old woman with massive weight loss who had gastric bypass surgery. **B,** Postoperative view 2½ years after abdominoplasty. She also underwent breast surgery, thighlift, backlift with excision of excess skin of the lower back and upper buttocks, and upper arm surgery.

around the waist and upper thighs. A long, hollow, stainless steel cannula is inserted through a small incision over the fatty tissue to be suctioned. This surgical procedure is not usually recommended for the older person because the skin is less elastic and will not accommodate the new underlying shape.

NURSING MANAGEMENT
PERIOPERATIVE CARE OF THE OBESE PATIENT

NURSING IMPLEMENTATION

This section discusses general nursing considerations for the care of the obese patient who is having surgery. Special nursing considerations are described for the patient who is having bariatric surgery. (Care of the surgical patient is discussed in Chapters 18 to 20.)

PREOPERATIVE CARE. Special considerations are necessary for the obese patient, especially the severely obese individual, who is admitted to the hospital for surgery.[26] Before surgery, interview the patient to identify past and current health information and any assistive devices currently in use (e.g., continuous positive airway pressure [CPAP] for sleep apnea). Co-morbidities secondary to obesity increase the risk for complications in the perioperative period. It may be necessary to coordinate care

with the patient's cardiologist, pulmonologist, gynecologist, gastroenterologist, or other specialists.

Have a plan in place before the patients arrive so they receive optimal care and do not feel like they are a burden to the nursing staff. Nursing units must have available appropriate size hospital gowns, beds that accommodate an increased body size, and necessary patient transfer equipment. To correctly measure BP in obese people, a larger cuff size is needed to avoid artifactual errors. Ensure that oversized BP cuffs are available and placed in the patient's room.

Consider how the patient will be weighed and transported throughout the hospital. A wheelchair with removable arms that is large enough to safely accommodate the patient and pass easily through doorways should be available.

Preoperative and postoperative assessment of heart, lung, and bowel sounds may require the use of alternative assessment techniques. For example, because of the large chest wall, breath and heart sounds are often distant. Electronic stethoscopes can be used to amplify lung, heart, and bowel sounds. Pulse oximetry may also be used to assess oxygenation status.

Instruct the patient in the proper coughing and deep breathing techniques and methods of turning and positioning to prevent pulmonary complications after surgery. If possible, demonstrate the use of a spirometer before surgery. Use of the spirometer helps prevent and treat postoperative lung congestion. Practicing these strategies preoperatively can help the patient perform them correctly postoperatively. Furthermore, if the patient uses CPAP at home for sleep apnea, make arrangements for the use of a machine while the patient is hospitalized.

Obtaining venous access may be complicated by excess adipose tissue. A longer IV catheter is helpful (longer than 1 in) to go through the overlying tissue to the vein. It is important that the cannula is far enough into the vein to ensure that it is not dislodged or infiltrated.

Special Considerations for Bariatric Surgery. Ensure that the patient scheduled for bariatric surgery understands the surgical procedure. Your teaching depends on the type of procedure and surgical approach.

Prepare the patient before surgery for the possibility of returning with one or more of the following: urinary catheter, IV catheter, compression stockings, and nasogastric tube. Emphasize that vital signs and a general assessment will be conducted frequently to monitor for complications. Further, the patient must understand that he or she will be assisted with ambulation soon after surgery and encouraged to cough and deep breathe to prevent pulmonary complications. Liquids will be started early but only after the patient is fully awake and there is no evidence of any anastomosis leaks.

POSTOPERATIVE CARE. The initial postoperative care focuses on careful assessment and immediate intervention for cardiopulmonary complications, thrombus formation, anastomosis leaks, and electrolyte imbalances. The transfer from surgery may require many trained staff members. During the transfer, the patient's airway should remain stabilized and attention given to managing the patient's pain. Maintain the patient's head at a 35- to 40-degree angle to reduce abdominal pressure and increase lung expansion.

The body stores anesthetics in adipose tissue, thus placing patients with excess adipose tissue at risk for re-sedation. As adipose cells release anesthetics back into the bloodstream, the patient may become sedated after surgery. If this happens, be prepared to perform a head-tilt or jaw-thrust maneuver and keep the patient's oral and nasal airways open.[27]

Diligence in turning and ambulation postoperatively will prevent complications from surgery. Tell the patient that typically he or she will be assisted in walking the evening after surgery and then at least three or four times each day. The patient may be reluctant to move or may not have the stamina to walk even a short distance. In either situation, you will need additional help in facilitating movement in an obese patient.

Obesity can cause a patient's breathing to become shallow and rapid. The extra adipose tissue in the chest and abdomen compresses the diaphragmatic, thoracic, and abdominal structures. This compression restricts the chest's ability to expand, preventing the lungs from working as efficiently as they would otherwise. The patient retains more carbon dioxide with less oxygen delivered to the lungs. This results in hypoxemia, pulmonary hypertension, and polycythemia.

Postoperatively the risk for deep venous thrombosis (DVT) is increased. Venous stasis is common due to the pressure on the veins. Antiembolic stockings or sequential compression stockings may be ordered along with low-dose heparin to minimize the risk of a DVT. Active and passive range-of-motion exercises are a frequent part of daily care.

Wound infection, dehiscence, and delayed healing are potential problems for all obese patients. Assess the patient's skin for any complications related to wound healing. Keep skinfolds clean and dry to prevent dermatitis and secondary bacterial or fungal infections.

Special Considerations for Bariatric Surgery. Patients experience considerable abdominal pain after bariatric surgery. Give pain medications as necessary during the immediate postoperative period (first 24 hours). Be aware that pain could be from an anastomosis leak rather than typical surgical pain.

Abdominal wounds require frequent observation for the amount and type of drainage, condition of the incision, and signs of infection. Protect the incision against undue straining that accompanies turning and coughing. Monitor vital signs to assist in identifying problems such as infection.

If a nasogastric tube is inserted, monitor it for patency and keep it in the correct position. If the patient vomits with a nasogastric tube in place, it may require repositioning; notify the surgeon immediately. The upper gastric pouch is small, and irrigating the tube with too much solution or manipulating the tube position can lead to disruption of the anastomosis or staple line.

During the immediate postoperative period water and sugar-free clear liquids are given (30 mL every 2 hours while awake). Before discharge, instruct patients on a measured amount of a high-protein liquid diet. The patient is taught to eat slowly, stop eating when feeling full, and not consume liquids with solid food. Vomiting is a common complication during this time. A dietitian is usually part of the bariatric team and assists the patient with the transition to the new diet.

AMBULATORY AND HOME CARE

Special Considerations for Bariatric Surgery. The patient who has undergone major surgical treatment for obesity has not been successful in the past in following or maintaining a prescribed diet. Now the patient is forced to reduce oral intake because of the anatomic changes from the surgical procedure. The patient's adherence to a reduced intake is necessary because of the concern for abdominal distention, cramping abdominal pain, and perhaps diarrhea.

Weight loss is considerable during the first 6 to 12 months. During this time the patient must learn to adjust intake sufficiently to maintain a stable weight. Although behavior modification is not necessarily an intended outcome with these surgical procedures, it becomes an unexpected secondary gain. For example, a person who has had bariatric surgery cannot overeat or binge eat without consequences.

The diet generally prescribed should be high in protein and low in carbohydrates, fat, and roughage and consist of six small feedings daily. Fluids should not be ingested with the meal, and in some cases, fluids should be restricted to less than 1000 mL/day. Fluids and foods high in carbohydrate tend to promote diarrhea and symptoms of the dumping syndrome. Generally, calorically dense foods (foods high in fat) should be avoided to permit more nutritionally sound food to be consumed.

The patient must clearly understand the proper diet. Late complications can be anticipated after bariatric surgery, including anemia, vitamin deficiencies, diarrhea, and psychologic problems. Failure to lose weight or loss of too much weight may be caused by the surgical formation of too large a stomach pouch or of an outlet that is much too small, respectively. Peptic ulcer formation, dumping syndrome, and small bowel obstruction may be seen late in the recovery and rehabilitation stage.

Emphasize the importance of long-term follow-up care, in part because of potential complications late in the recovery period. Encourage patients to adhere strictly to the prescribed diet and to inform the health care provider of any changes in their physical or emotional condition. Some patients have been known to overeat when they return home and gain rather than lose weight.

Several potential psychologic problems may arise after surgery. Some patients express guilt feelings that weight loss was achieved by surgical interventions rather than by the "sheer willpower" of reduced dietary intake and exercise. Be ready to provide support and assist the patient in moving away from such negative feelings.

By 6 to 8 months after surgery, considerable weight loss has occurred, and patients are able to see how much their appearance has changed. Discussion of this possible outcome with the patient before surgery and again during the rehabilitation phase facilitates the patient's adjustment to a new body image. Do not hesitate to encourage counseling for unresolved psychologic issues.

Massive weight loss often leaves the patient with large quantities of flabby skin that can result in problems related to altered body image. Reconstructive surgery may alleviate this situation. Reductions of the breasts, upper arms, thighs, and excess abdominal skinfolds are possible solutions.

Often one result of bariatric surgery is the return of fertility in women. Pregnancy complications can result from anemia and nutritional deficiencies. Furthermore, depending on the type of surgery, intestinal obstructions and hernias are commonly experienced in pregnancy.[28] Gallbladder problems may also arise, leading to pancreatitis. Women must carefully consider the risk of pregnancy after bariatric surgery. In general, encourage women to postpone pregnancy for 12 to 18 months after bariatric surgery.[28]

EVALUATION

The expected outcomes are that the obese patient will

- Experience long-term weight loss
- Have improvement in obesity-related co-morbidities
- Integrate healthy practices into daily routines
- Monitor for adverse side effects of surgical therapy
- Have an improved self-image

EVIDENCE-BASED PRACTICE

Applying the Evidence

W.G. is a 35-yr-old male patient weighing 367 lb (166.4 kg) with a BMI of 54.3 kg/m^2. He underwent gastric bypass surgery and is now ready for discharge. The bariatric program at your institution recommends the attendance at support groups after surgery. W.G. informs you that he does not feel comfortable in group settings and will not be attending these meetings.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Patients attending psychotherapeutic interventions or support groups in combination with bariatric surgery experience greater weight loss results than patients treated with only bariatric surgery.	You have heard from several former bariatric patients who have maintained their weight loss after surgery and attributed this success, in part, to their participation in the support group offered at your facility.	Patient does not feel comfortable in group settings.

Your Decision and Action

You explore W.G.'s feelings about groups and share the reports from former patients with him. He continues to be firm about his unwillingness to attend any support groups. You discuss with him that it is his decision and you will help monitor his progress. Gently remind him that he can change his decision at any time. Inform his physician of his choice.

GERONTOLOGIC CONSIDERATIONS

OBESITY IN OLDER ADULTS

The prevalence of obesity is increasing in all age-groups, including older people. The number of obese older persons has markedly risen because of increases in both the total number of older persons and the percentage of the older adults who are obese. Obesity is more common in older women than in older men. A decrease in energy expenditure is an important contributor to a gradual increase in body fat with age.

Obesity in older adults can exacerbate age-related declines in physical function and lead to frailty and disability. Obesity is associated with decreased survival. Individuals who are obese live 6 to 7 years less than people of normal weight do.

Many of the changes associated with aging are exacerbated by obesity. Excess body weight places more demands on arthritic joints. The mechanical strain on weight-bearing joints can lead to premature immobility. Excess weight also affects other body systems. Older adults may find that excess intraabdominal weight causes problems with urinary incontinence. In addition, excess weight may contribute to hypoventilation and sleep apnea.

TABLE 41-10 CRITERIA FOR METABOLIC SYNDROME*

Measure	Criteria
Waist circumference	≥40 in (102 cm) in men ≥35 in (89 cm) in women
Triglycerides	>150 mg/dL (1.7 mmol/L) OR Drug treatment for elevated triglycerides
High-density lipoprotein (HDL) cholesterol	<40 mg/dL (0.9 mmol/L) in men <50 mg/dL (1.1 mmol/L) in women OR Drug treatment for reduced HDL cholesterol
BP	≥130 mm Hg systolic BP OR ≥85 mm Hg diastolic BP OR Drug treatment for hypertension
Fasting blood glucose	≥110 mg/dL OR Drug treatment for elevated glucose

Source: National Heart, Lung, and Blood Institute: How is metabolic syndrome diagnosed? Retrieved from *www.nhlbi.nih.gov/health/dci/Diseases/ms/ms_diagnosis.html*.

*Any three of the five measures are needed for a diagnosis of metabolic syndrome.

PATHOPHYSIOLOGY MAP

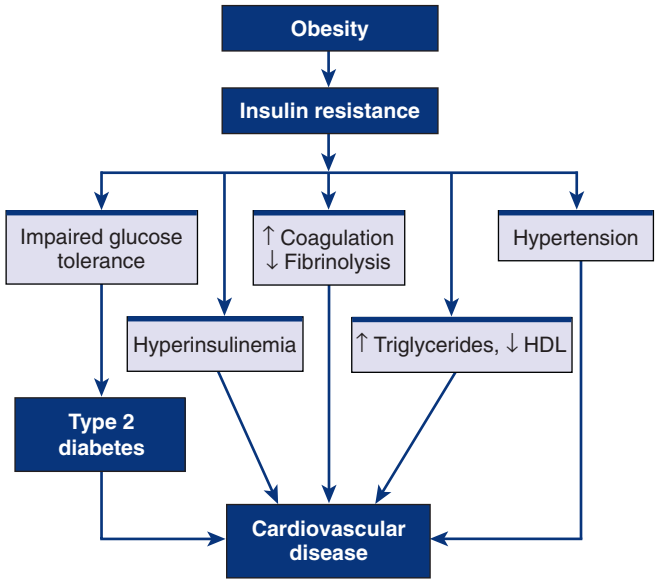

FIG. 41-7 Relationship among insulin resistance, obesity, diabetes mellitus, and cardiovascular disease. *HDL,* High-density lipoprotein.

Obesity affects the quality of life for older adults. Weight loss can improve physical functioning and obesity-related health complications. The same therapeutic approaches for obesity as were discussed earlier also apply to the older adult.

METABOLIC SYNDROME

Metabolic syndrome, also known as *syndrome X, insulin resistance syndrome,* and *dysmetabolic syndrome,* is a collection of risk factors that increase an individual's chance of developing cardiovascular disease, stroke, and diabetes mellitus. It is estimated that around 70 million to 80 million, or about 25%, of Americans have metabolic syndrome.[29] The syndrome is more prevalent in those 60 years of age and older.[30]

Metabolic syndrome is characterized by a cluster of health problems, including obesity, hypertension, abnormal lipid levels, and high blood glucose. Metabolic syndrome is diagnosed if an individual has three or more of the conditions listed in Table 41-10.

Currently health professionals are debating the usefulness of focusing attention on the syndrome itself. The interventions are focused on each risk factor, since there is not one standard treatment for the syndrome itself.[30]

Etiology and Pathophysiology

The main underlying risk factor for metabolic syndrome is insulin resistance related to excessive visceral fat (Fig. 41-7). Insulin resistance is the body's cells diminished ability to respond to the action of insulin. The pancreas compensates by secreting more insulin, resulting in hyperinsulinemia.

Other characteristics of metabolic syndrome include hypertension, increased risk for clotting, and abnormalities in cholesterol levels. The net effect of these conditions is an increased prevalence of coronary artery disease.

Genetics and environment have important roles in the development of metabolic syndrome. African Americans, Hispanics, Native Americans, and Asians are at an increased risk for metabolic syndrome. Environmental factors that influence the chances of having the syndrome are the same involved in the development of obesity. Metabolic syndrome is also associated with aging.

Clinical Manifestations and Diagnostic Studies

The signs of metabolic syndrome are impaired fasting blood glucose, hypertension, abnormal cholesterol levels, and obesity. Medical problems develop over time if the condition remains unaddressed. Patients with this syndrome are at a higher risk of heart disease, stroke, diabetes, renal disease, and polycystic ovary syndrome. Patients who have metabolic syndrome and smoke are at an even higher risk.

NURSING AND COLLABORATIVE MANAGEMENT METABOLIC SYNDROME

Lifestyle modifications are the first-line interventions to reduce the risk factors for metabolic syndrome. Management or reversal of metabolic syndrome can be achieved by reducing the major risk factors of cardiovascular disease: reducing LDL cholesterol, stopping smoking, lowering BP, and reducing glucose levels. For long-term risk reduction, weight should be decreased, physical activity increased, and healthy dietary habits established.

There is no specific management of metabolic syndrome. You can assist patients by providing information on healthy diets, exercise, and positive lifestyle changes. The diet, which should be low in saturated fats, should promote weight loss. Weight reduction and maintenance of a lower weight should be the first priority in those with abdominal obesity and metabolic syndrome.

Because sedentary lifestyles contribute to metabolic syndrome, increasing regular physical activity will lower a patient's risk factors. In addition to assisting in weight reduction, regular

CASE STUDY

Obesity

Hemera/Thinkstock

Patient Profile

S.R. is a 48-yr-old white woman.

Subjective Data

- Reports gradual weight gain of 40 lb during past 40 yr
- Lives in a rural community with no sidewalks
- Spends most of her free time watching television
- Reports health problems related to type 2 diabetes mellitus, shortness of breath, hypertension, and osteoarthritis
- Had knee replacement surgery at age 46 for osteoarthritis

Objective Data

Physical Examination

- 5 ft, 4 in tall; weighs 210 lb; waist circumference of 39 in
- Has obese, nontender, soft round, abdomen
- BP 160/100 mm Hg

Laboratory Results

- Fasting blood glucose 250 mg/dL (13.9 mmol/L)
- Total cholesterol 205 mg/dL (5.3 mmol/L)
- Triglyceride 298 mg/dL (3.36 mmol/L)
- HDL cholesterol 31 mg/dL (0.8 mmol/L)
- LDL cholesterol 114 mg/dL

Discussion Questions

1. What are S.R.'s risk factors for obesity?
2. What is her estimated BMI?
3. Of the possible complications of obesity, which ones does S.R. have? Why did she develop them?
4. ***Priority Decision:*** How would you assist S.R. in designing a successful weight loss and weight management program?
5. What are S.R.'s risk factors for metabolic syndrome?
6. Is S.R. a candidate for surgical intervention for obesity? Why or why not?
7. ***Evidence-Based Practice:*** S.R. tells you that she is motivated to lose weight and thinks that she can "do it on her own." Based on your understanding of the evidence, is this the best approach for her to be successful in losing weight?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

exercise has been found to decrease the triglyceride level and increase the HDL cholesterol level in patients with metabolic syndrome.

Patients unable to lower risk factors with lifestyle therapies alone or those at high risk for a coronary event or diabetes may be considered for drug therapy. Although there is no specific medication for metabolic syndrome, cholesterol-lowering and antihypertensive drugs can be used. Metformin (Glucophage) has also been used to prevent diabetes by lowering glucose levels and enhancing the cells' sensitivity to insulin.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. Which statement best describes the etiology of obesity?
   - **a.** Obesity primarily results from a genetic predisposition.
   - **b.** Psychosocial factors can override the effects of genetics in the etiology of obesity.
   - **c.** Obesity is the result of complex interactions between genetic and environmental factors.
   - **d.** Genetic factors are more important than environmental factors in the etiology of obesity.
2. The obesity classification that is most often associated with cardiovascular health problems is
   - **a.** primary obesity.
   - **b.** secondary obesity.
   - **c.** gynoid fat distribution.
   - **d.** android fat distribution.
3. Health risks associated with obesity include *(select all that apply)*
   - **a.** colorectal cancer.
   - **b.** rheumatoid arthritis.
   - **c.** polycystic ovary syndrome.
   - **d.** nonalcoholic steatohepatitis.
   - **e.** systemic lupus erythematosus.
4. The best nutritional therapy plan for a person who is obese is
   - **a.** the Zone diet.
   - **b.** the Atkins diet.
   - **c.** Sugar Busters.
   - **d.** foods from the basic food groups.
5. This bariatric surgical procedure involves creating a stoma and gastric pouch that is reversible, and no malabsorption occurs. What surgical procedure is this?
   - **a.** Vertical gastric banding
   - **b.** Biliopancreatic diversion
   - **c.** Roux-en-Y gastric bypass
   - **d.** Adjustable gastric banding
6. A severely obese patient has undergone Roux-en-Y gastric bypass surgery. In planning postoperative care, the nurse anticipates that the patient
   - **a.** may have severe diarrhea early in the postoperative period.
   - **b.** will not be allowed to ambulate for 1 to 2 days postoperatively.
   - **c.** will require nasogastric suction until the incision heals.
   - **d.** may have only liquids orally, and in very limited amounts, during the early postoperative period.
7. Which of the following criteria must be met for a diagnosis of metabolic syndrome *(select all that apply)?*
   - **a.** Hypertension
   - **b.** Elevated triglycerides
   - **c.** Elevated plasma glucose
   - **d.** Increased waist circumference
   - **e.** Decreased low-density lipoproteins

1. c, 2. d, 3. a, c, d, 4. d, 5. d, 6. d, 7. a, b, c, d

LEARNING OUTCOMES

1. Describe the etiology, complications, collaborative care, and nursing management of nausea and vomiting.
2. Describe the etiology, clinical manifestations, and treatment of common oral inflammations and infections.
3. Describe the etiology, clinical manifestations, complications, collaborative care, and nursing management of oral cancer.
4. Explain the types, pathophysiology, clinical manifestations, complications, and collaborative care (including surgical therapy and nursing management) of gastroesophageal reflux disease (GERD) and hiatal hernia.
5. Describe the pathophysiology, clinical manifestations, complications, and collaborative care of esophageal cancer, diverticula, achalasia, and esophageal strictures.
6. Differentiate between acute and chronic gastritis, including the etiology, pathophysiology, collaborative care, and nursing management.
7. Compare and contrast gastric and duodenal ulcers, including the etiology, pathophysiology, clinical manifestations, complications, collaborative care, and nursing management.
8. Describe the clinical manifestations, collaborative care, and nursing management of stomach cancer.
9. Explain the common etiologies, clinical manifestations, collaborative care, and nursing management of upper gastrointestinal bleeding.
10. Identify common types of foodborne illnesses and nursing responsibilities related to food poisoning.

NAUSEA AND VOMITING

Nausea and vomiting are the most common manifestations of gastrointestinal (GI) diseases. Although nausea and vomiting can occur independently, they are usually closely related and treated as one problem. **Nausea** is a feeling of discomfort in the epigastrium with a conscious desire to vomit. **Vomiting** is the forceful ejection of partially digested food and secretions *(emesis)* from the upper GI tract.

Vomiting is a complex act that requires the coordinated activities of several structures: closure of the glottis, deep inspiration with contraction of the diaphragm in the inspiratory position, closure of the pylorus, relaxation of the stomach and lower esophageal sphincter (LES), and contraction of the abdominal muscles with increasing intraabdominal pressure. These simultaneous activities force the stomach contents up through the esophagus, into the pharynx, and out the mouth.

Etiology and Pathophysiology

Nausea and vomiting occur in a wide variety of GI disorders and in conditions that are unrelated to GI disease. These include pregnancy; infection; central nervous system (CNS)

Reviewed by Marian Sawyier, RN, MSN, Staff Nurse, University of New Mexico Hospital, Albuquerque, New Mexico.

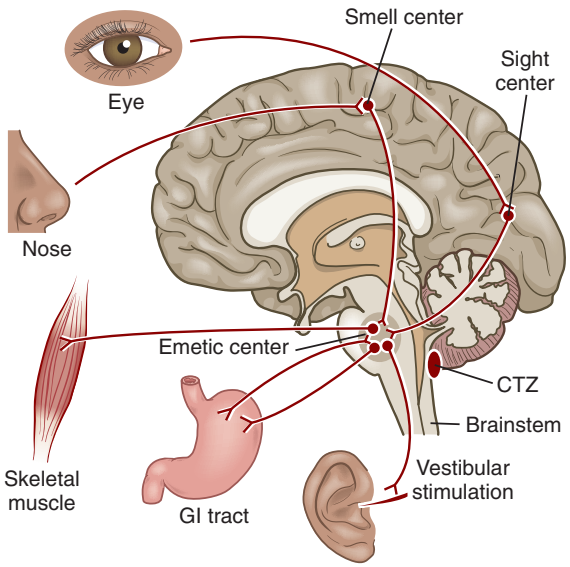

FIG. 42-1 Stimuli involved in the act of vomiting. *CTZ,* Chemoreceptor trigger zone.

disorders (e.g., meningitis, tumor); cardiovascular problems (e.g., myocardial infarction, heart failure); metabolic disorders (e.g., diabetes mellitus, Addison's disease, renal failure); postoperatively after general anesthesia; side effects of drugs (e.g., chemotherapy, opioids, digitalis); psychologic factors (e.g., stress, fear); and conditions in which the GI tract becomes overly irritated, excited, or distended.

A vomiting center in the brainstem coordinates the multiple components involved in vomiting. This center receives input from various stimuli. Neural impulses reach the vomiting center via afferent pathways through branches of the autonomic nervous system. Receptors for these afferent fibers are located in the GI tract, kidneys, heart, and uterus. When stimulated, these receptors relay information to the vomiting center, which then initiates the vomiting reflex (Fig. 42-1).

The chemoreceptor trigger zone (CTZ) located in the brainstem responds to chemical stimuli of drugs, toxins, and labyrinthine stimulation (e.g., motion sickness). Once stimulated, the CTZ transmits impulses directly to the vomiting center. This action activates the autonomic nervous system, resulting in both parasympathetic and sympathetic stimulation. Sympathetic activation produces tachycardia, tachypnea, and diaphoresis. Parasympathetic stimulation causes relaxation of the LES, an increase in gastric motility, and a pronounced increase in salivation.

Clinical Manifestations

Nausea is a subjective complaint. *Anorexia* (lack of appetite) usually accompanies nausea. When nausea and vomiting occur over a long period, dehydration can develop rapidly. Water and essential electrolytes (e.g., potassium, sodium, chloride, hydrogen) are lost. As vomiting persists, the patient may have severe electrolyte imbalances, loss of extracellular fluid volume, decreased plasma volume, and eventually circulatory failure.

Metabolic alkalosis can result from loss of gastric hydrochloric (HCl) acid. When contents of the small intestine are vomited, metabolic acidosis can occur. However, metabolic acidosis is less common than metabolic alkalosis. Weight loss resulting from fluid loss is evident in a short time when vomiting is severe.

The threat of pulmonary aspiration is a concern when vomiting occurs in older or unconscious patients or in patients with other conditions that impair the gag reflex. To prevent aspiration, put the patient who cannot adequately manage self-care in a semi-Fowler's or side-lying position.

Collaborative Care

The goals of collaborative care are to determine and treat the underlying cause of the nausea and vomiting and to provide symptomatic relief. Assess the patient for precipitating factors, and describe the contents of the emesis. Women are more likely to suffer from nausea and vomiting associated with surgical procedures and motion sickness.[1]

It is important to differentiate among vomiting, regurgitation, and projectile vomiting. *Regurgitation* is an effortless process in which partially digested food slowly comes up from the stomach. Retching or vomiting rarely occurs before it. *Projectile vomiting* is a forceful expulsion of stomach contents without nausea and is characteristic of CNS (brain and spinal cord) tumors.

Emesis containing partially digested food several hours after a meal is indicative of gastric outlet obstruction or delayed gastric emptying. The presence of fecal odor and bile after prolonged vomiting suggests intestinal obstruction below the level of the pylorus. Bile in the emesis may suggest obstruction below the ampulla of Vater. The color of the emesis aids in identifying the presence and source of bleeding. Vomitus with a "coffee ground" appearance is related to gastric bleeding, where blood changes to dark brown as a result of its interaction with HCl acid. Bright red blood indicates active bleeding. This could be due to a **Mallory-Weiss tear** (disruption of the mucosal lining near the esophagogastric junction), esophageal varices, gastric or duodenal ulcer, or neoplasm. A Mallory-Weiss tear is most often related to severe retching and vomiting.

The time of day at which the vomiting occurs is often helpful in determining the cause. Early morning vomiting is common in pregnancy. Emotional stressors with no evident pathologic disorder may elicit vomiting during or immediately after eating.

Drug Therapy. The use of drugs (Table 42-1) in the treatment of nausea and vomiting depends on the cause of the problem. Because the cause cannot always be readily determined, use drugs with caution. Using antiemetics before determining the cause can mask the underlying disease process and delay diagnosis and treatment. Many antiemetic drugs act in the CNS via the CTZ to block the neurochemicals that trigger nausea and vomiting.

DRUG ALERT: Promethazine Injection

- Promethazine should not be administered into an artery or under the skin because of the risk of severe tissue injury, including gangrene.
- When promethazine is administered IV, it can leach out from the vein and cause serious damage to surrounding tissue.
- Deep muscle injection is the preferred route of injection administration.

DRUG ALERT: Metoclopramide (Reglan)

- Chronic use or high doses of metoclopramide carry the risk of tardive dyskinesia.
- Tardive dyskinesia is a neurologic condition characterized by involuntary and repetitive movements of the body (e.g., extremity movements, lip smacking).
- With discontinuation of the drug, the tardive dyskinesia persists.

The serotonin (5-HT_3) receptor antagonists are effective in reducing cancer chemotherapy–induced vomiting caused by delayed gastric emptying and also the nausea and vomiting

TABLE 42-1 DRUG THERAPY

Nausea and Vomiting

Drug	Mechanism of Action	Side Effects
Phenothiazines		
chlorpromazine (Thorazine) perphenazine (Trilafon) prochlorperazine (Compazine) trifluoperazine (Stelazine) promethazine (Phenergan)	Act in the CNS level of the CTZ Block dopamine receptors that trigger nausea and vomiting	Dry mouth, hypotension, sedative effects, rashes, constipation
Antihistamines		
meclizine (Bonine, Antivert) dimenhydrinate (Dramamine) hydroxyzine (Vistaril) diphenhydramine (Benadryl)	Block the histamine receptors that trigger nausea and vomiting	Dry mouth, hypotension, sedative effects, rashes, constipation
Prokinetic Agents		
domperidone (Motilium) metoclopramide (Reglan)	Inhibit action of dopamine ↑ Gastric motility and emptying	CNS side effects ranging from anxiety to hallucinations Extrapyramidal side effects, including tremor and dyskinesias (similar to Parkinson's disease)
Serotonin (5-HT_3) Antagonists		
dolasetron (Anzemet) granisetron (Kytril) ondansetron (Zofran) palonosetron (Aloxi)	Block the action of serotonin (substance that causes nausea and vomiting)	Constipation, diarrhea, headache, fatigue, malaise, elevated liver function tests
Anticholinergic (Antimuscarinic)		
scopolamine transdermal	Blocks the cholinergic pathways to the vomiting center	Xerostomia, somnolence
Butyrophenone		
droperidol (Inapsine)	Blocks the neurochemicals that trigger nausea and vomiting	Dry mouth, hypotension, sedative effects, rashes, constipation
Others		
aprepitant (Emend) dexamethasone (Decadron) dronabinol (Marinol) nabilone (Cesamet) thiethylperazine (Torecan) trimethobenzamide (Tigan)		

CTZ, Chemoreceptor trigger zone.

related to migraine headache and anxiety.[2] 5-HT_3 antagonists are also used in prevention and treatment of postoperative nausea and vomiting. Dexamethasone (Decadron) is used in the management of both acute and delayed cancer chemotherapy–induced emesis, usually in combination with other antiemetics such as ondansetron (Zofran). Aprepitant (Emend), a substance P/neurokinin-1 receptor antagonist, is used for the prevention of chemotherapy-induced and postoperative nausea and vomiting.

Dronabinol (Marinol) is an orally active cannabinoid that is used alone or in combination with other antiemetics for the prevention of chemotherapy-induced emesis. Because of the potential for abuse, as well as drowsiness and sedation, this drug is used only when other therapies are ineffective.

Nutritional Therapy. The patient with severe vomiting requires IV fluid therapy with electrolyte and glucose replacement until able to tolerate oral intake. In some cases a nasogastric (NG) tube and suction are used to decompress the stomach. Start oral nutrition beginning with clear liquids once symptoms have subsided. Extremely hot or cold liquids are often difficult to tolerate. Carbonated beverages at room temperature and with the carbonation gone and warm tea are easier to tolerate. The addition of dry toast or crackers may be helpful. Water is the initial fluid of choice for rehydration by mouth. Sipping small amounts of fluid (5 to 15 mL) every 15 to 20 minutes is usually better tolerated than drinking large amounts less frequently. Broth and Gatorade are high in sodium, so administer them with caution.

As the patient's condition improves, provide a diet high in carbohydrates and low in fat. Items such as a baked potato, plain gelatin, cereal, and hard candy are ideal. Coffee, spicy foods, highly acidic foods, and those with strong odors are often poorly tolerated. Tell the patient to eat food slowly and in small amounts to prevent overdistention of the stomach. Liquids taken between meals rather than with meals also reduce overdistention. Consult a dietitian regarding appropriate foods that have nutritional value and are well tolerated by the patient.

Nondrug Therapy. For some patients, acupressure or acupuncture at specific points is effective in reducing postoperative nausea and vomiting.[3] Some patients use herbs such as ginger and peppermint oil. Relaxation breathing exercises, changes in body position, or exercise may be helpful for some patients.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Ginger

Scientific Evidence

- Some evidence that ginger may be effective for nausea and vomiting of pregnancy when used at recommended doses for short periods
- Unclear scientific evidence for the use of ginger for nausea and vomiting related to other conditions

Nursing Implications

- Few adverse effects have been reported with short-term use.
- Ginger may inhibit platelet aggregation and increase risk of bleeding.
- It may lower blood glucose levels.

NURSING MANAGEMENT NAUSEA AND VOMITING

NURSING ASSESSMENT

Each patient with a history of prolonged and persistent nausea or vomiting requires a thorough nursing assessment before you develop a specific plan of care. Although numerous conditions are associated with nausea and vomiting, you should have a basic understanding of the more common conditions and be able to identify the patient who is at high risk. Knowledge of the physiologic mechanisms involved in nausea and vomiting is important in the assessment process. Table 42-2 presents subjective and objective data to be obtained from a patient with nausea and vomiting.

NURSING DIAGNOSES

Nursing diagnoses for the patient with nausea and vomiting may include, but are not limited to, the following:

- Nausea *related to* multiple etiologies
- Deficient fluid volume *related to* prolonged vomiting
- Imbalanced nutrition: less than body requirements *related to* nausea and vomiting

Additional information on nursing diagnoses is presented in eNursing Care Plan 42-1 on the website for this chapter.

PLANNING

The overall goals are that the patient with nausea and vomiting will (1) experience minimal or no nausea and vomiting, (2) have normal electrolyte levels and hydration status, and (3) return to a normal pattern of fluid balance and nutrient intake.

NURSING IMPLEMENTATION

ACUTE INTERVENTION. Most people with nausea and vomiting can be managed at home. When nausea and vomiting persist, hospitalization may be necessary for diagnosis of the underlying problem. Until a diagnosis is confirmed, the patient is on nothing-by-mouth (NPO) status and given IV fluids. An NG tube connected to suction may be needed for the patient with persistent vomiting or when a bowel obstruction or paralytic ileus is suspected. Secure the NG tube to prevent its movement in the nose and back of the throat because this can stimulate nausea and vomiting.

With prolonged vomiting, there is a probability of dehydration and acid-base and electrolyte imbalances. Provide explanations regarding diagnostic tests or procedures performed. Record intake and output, position the patient to prevent aspiration, and monitor vital signs. Assess for signs of dehydration, and observe for changes in the patient's physical comfort and mentation. Provide physical and emotional support, and maintain a quiet, odor-free environment.

AMBULATORY AND HOME CARE. Teach the patient and the caregiver (1) how to manage the unpleasant sensation of nausea, (2) methods to prevent nausea and vomiting, and (3) strategies to maintain fluid and nutritional intake. You can minimize the occurrence of nausea or vomiting by keeping the immediate environment quiet, free of noxious odors, and well ventilated. Avoiding sudden changes of position and unnecessary activity is also helpful. Use of relaxation techniques, frequent rest periods, effective pain management strategies, and diversional tactics can prevent or reduce nausea and vomiting. Cleansing the face and hands with a cool washcloth and providing mouth care between episodes increase the person's comfort level. When symptoms occur, stop all foods and drugs until the acute phase is over.

If you suspect a medication is the cause, notify the health care provider immediately so that either the dosage can be altered or a new drug prescribed. Advise the patient that stopping the drug without consulting the health care provider may have detrimental effects on the person's health.

When food is the precipitating cause of nausea and vomiting, help the patient identify the specific food. In addition,

TABLE 42-2 NURSING ASSESSMENT

Nausea and Vomiting

Subjective Data

Important Health Information

Past health history: GI disorders, chronic indigestion, food allergies, pregnancy, infection, CNS disorders, recent travel, bulimia, metabolic disorders, cancer, cardiovascular disease, renal disease

Medications: Antiemetics, digitalis, opioids, ferrous sulfate, aspirin, aminophylline, alcohol, antibiotics; general anesthesia; chemotherapy

Surgery or other treatments: Recent surgery

Functional Health Patterns

Nutritional-metabolic: Amount, frequency, character, and color of vomitus; dry heaves; anorexia; weight loss

Activity-exercise: Weakness, fatigue

Cognitive-perceptual: Abdominal tenderness or pain

Coping–stress tolerance: Stress, fear

Objective Data

General

Lethargy, sunken eyeballs

Integumentary

Pallor, dry mucous membranes, poor skin turgor

Gastrointestinal

Amount, frequency, character (e.g., projectile), content (undigested food, blood, bile, feces), and color of vomitus (red, "coffee ground," green-yellow)

Urinary

Decreased output, concentrated urine

Possible Diagnostic Findings

Altered serum electrolytes (especially hypokalemia), metabolic alkalosis, abnormal upper GI findings on endoscopy or abdominal x-rays

determine when it was eaten, prior history with that food, and whether anyone else in the family is sick.

A patient may be reluctant to resume fluid intake because of fear of nausea recurring. Suggest that he or she begin with clear liquids or cola beverages, Gatorade, tea or broth, dry crackers or toast, and then plain gelatin. Bland foods, such as pasta, rice, and cooked chicken, are generally well tolerated in small amounts. An antiemetic drug is taken only if prescribed by the health care provider. Taking over-the-counter (OTC) drugs for relief of symptoms may make the problem worse.

EVALUATION

The expected outcomes are that the patient with nausea and vomiting will

- Be comfortable with minimal or no nausea and vomiting
- Have electrolyte levels within normal range
- Be able to maintain adequate intake of fluids and nutrients

GERONTOLOGIC CONSIDERATIONS

NAUSEA AND VOMITING

The older adult experiencing nausea and vomiting requires careful assessment and monitoring, particularly during periods of fluid loss and subsequent rehydration therapy. Older patients are more likely to have cardiac or renal insufficiency that places them at greater risk for life-threatening fluid and electrolyte imbalances. Excessive replacement of fluid and electrolytes may result in adverse consequences for the person who has heart failure or renal disease. The older adult with a decreased level of consciousness may be at high risk for aspiration of vomitus. Close monitoring of the patient's physical status and level of consciousness during episodes of vomiting is important.

Older adults are particularly susceptible to the CNS side effects of antiemetic drugs, since these drugs may produce confusion and increase their risk for falls. Dosages should be reduced and efficacy closely evaluated. Institute safety precautions for these patients (e.g., removing rugs that may cause slipping).

ORAL INFLAMMATION AND INFECTIONS

Oral inflammation and infections may be due to specific mouth diseases or secondary to systemic disorders such as leukemia or vitamin deficiency. Oral inflammation and infections can severely impair oral ingestion. Common inflammations and infections of the oral cavity are presented in Table 42-3. The patient who is immunosuppressed (e.g., receiving chemotherapy for cancer) or using corticosteroid inhalant treatment for asthma is at risk for oral infections (e.g., candidiasis).

TABLE 42-3 INFECTIONS AND INFLAMMATION OF THE MOUTH

Infection or Inflammation	Etiology	Clinical Manifestations	Treatment
Gingivitis	Neglected oral hygiene, malocclusion, missing or irregular teeth, faulty dentistry, eating of soft rather than fibrous foods.	Inflamed gingivae and interdental papillae, bleeding during tooth brushing, development of pus, formation of abscess with loosening of teeth (periodontitis).	Prevention through health teaching, dental care, gingival massage, professional cleaning of teeth, fibrous foods, conscientious brushing habits with flossing.
Vincent's infection (acute necrotizing ulcerative gingivitis, trench mouth)	Fusiform bacteria, Vincent spirochetes; predisposing factors of stress, excessive fatigue, poor oral hygiene, nutritional deficiencies (B and C vitamins).	Painful, bleeding gingivae. Eroding necrotic lesions of interdental papillae, ulcerations that bleed, increased saliva with metallic taste, fetid mouth odor, anorexia, fever, general malaise.	Rest (physical and mental); avoidance of smoking and alcoholic beverages. Soft, nutritious diet. Correct oral hygiene habits. Topical applications of antibiotics. Mouth irrigations with chlorhexidine (Hibiclens) and saline solutions.
Oral candidiasis (moniliasis or thrush)	*Candida albicans* (a yeastlike fungus), debilitation, prolonged high-dose antibiotic or corticosteroid therapy.	Pearly, bluish white "milk-curd" membranous lesions on mucosa of mouth and larynx. Sore mouth, yeasty halitosis.	Miconazole buccal tablets (Oravig), nystatin or amphotericin B as oral suspension or buccal tablets. Good oral hygiene.
Herpes simplex (cold sore, fever blister)*	Herpes simplex virus (type 1 or 2), predisposing factors of upper respiratory tract infections, excessive exposure to sunlight, food allergies, emotional tension, onset of menstruation.	Lip lesions, mouth lesions, vesicle formation (single or clustered). Shallow, painful ulcers.	Spirits of camphor, corticosteroid cream, mild antiseptic mouthwash, viscous lidocaine; removal or control of predisposing factors, antiviral agents (e.g., acyclovir [Zovirax], famciclovir [Famvir], penciclovir [Denavir], valacyclovir [Valtrex]).
Aphthous stomatitis (canker sore)	Recurrent and chronic form of infection secondary to systemic disease, trauma, stress, or unknown causes.	Ulcers of mouth and lips, causing extreme pain. Ulcers surrounded by erythematous base.	Corticosteroids (topical or systemic), tetracycline oral suspension.
Parotitis (inflammation of parotid gland, surgical mumps)	Usually *Staphylococcus* species, *Streptococcus* species occasionally, debilitation and dehydration with poor oral hygiene, NPO status for an extended time.	Pain in area of gland and ear, absence of salivation, purulent exudate from gland, erythema, ulcers.	Antibiotics, mouthwashes, warm compresses; preventive measures such as chewing gum, sucking on hard candy (lemon drops), adequate fluid intake.
Stomatitis (inflammation of mouth)	Trauma, pathogens, irritants (tobacco, alcohol). Renal, liver, and hematologic diseases. Side effect of many cancer chemotherapy drugs and radiation.	Excessive salivation, halitosis, sore mouth.	Removal or treatment of cause, oral hygiene with soothing solutions, topical medications. Soft, bland diet.

*See Table 24-5.

Oral infections may predispose the patient to infections in other body organs. For example, the oral cavity is a potential reservoir for respiratory pathogens. In addition, oral pathogens have been associated with diabetes and heart disease.[4]

Regular and good oral and dental hygiene reduces oral infections and inflammation. Management of these conditions focuses on identification of the cause, elimination of infection, provision of comfort measures, and maintenance of nutritional intake.

ORAL CANCER

There are two types of oral cancer: *oral cavity cancer,* which starts in the mouth, and *oropharyngeal cancer,* which develops in the part of the throat just behind the mouth (called the oropharynx). *Head and neck squamous cell carcinoma* (HNSCC) is a term used for cancers of the oral cavity, pharynx, and larynx, which account for 90% of malignant oral tumors. Annually, oral cancer is diagnosed in 40,250 Americans, and it is estimated that 7850 people die from the disease.[5]

Oral cancer is more prevalent in African American men, and their survival rate is lower than that of white men. Oral cancer is more common after age 35, with 65 years being the average age of diagnosis. It is two times more common in men than in women. The 5-year survival rate is 83% for localized cancer and 61% for all stages of cancer of the oral cavity and pharynx combined.[5]

Most oral malignant lesions occur on the lower lip. Other common sites are the lateral border and undersurface of the tongue, the labial commissure, and the buccal mucosa. Carcinoma of the lip has the most favorable prognosis of any of the oral tumors because lip lesions are usually diagnosed earlier.

Etiology and Pathophysiology

Although the definitive cause of oral cancer is unknown, it has a number of predisposing factors (Table 42-4). The risk of developing oral cancer is related to the duration of tobacco use. A history of frequent alcohol consumption is reported by 75% to 80% of patients who develop oral cancer. More than 30% of patients with cancer of the lip have outdoor occupations, indicating that prolonged exposure to sunlight is a risk factor. Irritation from the pipe stem resting on the lip is a factor in pipe smokers. Human papillomavirus (HPV) contributes to 25% of oral cancer cases.[5] HPV-associated oropharyngeal cancer is associated with multiple sexual partners, especially multiple oral sex partners.[6]

Clinical Manifestations

The common manifestations of oral cancer are shown in Table 42-4. Patients may also report nonspecific symptoms such as chronic sore throat, sore mouth, and voice changes. *Leukoplakia,* called "smoker's patch," is a white patch on the mouth mucosa or tongue. It is often considered a precancerous lesion, although less than 15% of these lesions actually transform into malignant cells. The patch becomes *keratinized* (hard and leathery) and is sometimes described as hyperkeratosis. Leukoplakia is the result of chronic irritation, especially from smoking. *Erythroplasia* (erythroplakia), which is a red velvety patch on the mouth or tongue, is also a precancerous lesion. More than 50% of cases of erythroplakia progress to squamous cell carcinoma.

Cancer of the lip usually appears as an indurated, painless ulcer on the lip. The first sign of carcinoma of the tongue is an ulcer or area of thickening. Soreness or pain of the tongue may occur, especially when eating hot or highly seasoned foods. Cancerous lesions are most likely to develop in the proximal half of the tongue. Some patients experience limitation of movement of the tongue. Later symptoms of cancer of the tongue include increased salivation, slurred speech, **dysphagia** (difficulty swallowing), toothache, and earache. Approximately 30% of patients with oral cancer have an asymptomatic neck mass.

CULTURAL & ETHNIC HEALTH DISPARITIES

Oral, Pharyngeal, and Esophageal Problems

Nausea and Vomiting
- Asian Americans, Middle Easterners, and African Americans are more likely to experience nausea and vomiting than whites.

Cancers of Oral Cavity and Pharynx
- The incidence and mortality rates are higher in African American men than in whites.
- Death rates as a result of oral cancer are decreasing in whites but increasing in nonwhites.

Esophageal Cancer
- Highest incidence is in non-Hispanic white men.
- Higher incidence occurs in Alaska Natives than in whites.

Stomach Cancer
- Asian Americans and Pacific Islanders, Hispanics, and African Americans have higher rates of stomach cancer than non-Hispanic whites.
- Asian Americans show significantly higher survival rates than other ethnic groups.

TABLE 42-4 TYPES AND CHARACTERISTICS OF ORAL CANCER

Location	Predisposing Factors	Clinical Manifestations	Treatment
Lip	Constant overexposure to sun, ruddy and fair complexion, recurrent herpetic lesions, irritation from pipe stem, syphilis, immunosuppression	Indurated, painless ulcer	Surgical excision, radiation
Tongue	Tobacco, alcohol, chronic irritation, syphilis	Ulcer or area of thickening, soreness or pain Increased salivation, slurred speech, dysphagia, toothache, earache (later signs)	Surgery (hemiglossectomy or glossectomy), radiation
Oral cavity	Poor oral hygiene, tobacco usage (pipe and cigar smoking, snuff, chewing tobacco), chronic alcohol intake, chronic irritation (jagged tooth, ill-fitting prosthesis, chemical or mechanical irritants), human papillomavirus (HPV)	Leukoplakia, erythroplakia, ulcerations, sore spot, rough area, pain, dysphagia, a lump or thickening in the cheek A sore throat or a feeling that something is stuck Difficulty chewing and speaking (later signs)	Surgery (mandibulectomy, radical neck dissection, resection of buccal mucosa), internal and external radiation

TABLE 42-5 COLLABORATIVE CARE

Oral Cancer

Diagnostic	Collaborative Therapy*
• History and physical examination • Biopsy • Oral exfoliative cytology • Toluidine blue test • CT, MRI, PET	• Surgery • Surgical excision of the tumor • Radical neck dissection • Radiation (internal or external) • Combined surgical resection with radiation • Chemotherapy

*Any of these approaches may be used, depending on the primary lesion and the extent of metastasis.

Diagnostic Studies

Diagnostic tests are performed to identify oral dysplasias, which are precursors to oral cancer. Oral exfoliative cytologic study involves scraping the suspicious lesion and spreading this scraping on a slide for microscopic examination. The toluidine blue test is also used as a screening test for oral cancer. Toluidine blue is applied topically to stain an area, and cancer cells preferentially take up the dye. A negative cytologic smear or negative toluidine blue test does not necessarily rule out a malignant condition. Once cancer is diagnosed, computed tomography (CT), magnetic resonance imaging (MRI), and positron emission tomography (PET) are used in staging the oral cancer.[7]

Collaborative Care

Collaborative care of the patient with oral carcinoma usually consists of surgery, radiation, chemotherapy, or a combination of these (Table 42-5).

Surgical Therapy. Surgery remains the most effective treatment, especially for early-stage disease. Various surgical procedures may be performed, depending on the location and extent of the tumor. Many of the operations are radical procedures involving extensive resections. Some examples are partial *mandibulectomy* (removal of the mandible), *hemiglossectomy* (removal of half of the tongue), *glossectomy* (removal of the tongue), resections of the buccal mucosa and floor of the mouth, and radical neck dissection.

Radical neck dissection includes wide excision of the primary lesion with removal of the regional lymph nodes, the deep cervical lymph nodes, and their lymphatic channels. The following structures may also be removed or transected (depending on the extent of the primary lesion): sternocleidomastoid muscle and other closely associated muscles, internal jugular vein, mandible, submaxillary gland, part of the thyroid and parathyroid glands, and spinal accessory nerve. A tracheostomy is commonly performed along with the radical neck dissection. Drainage tubes are inserted into the surgical area and connected to suction to remove fluid and blood.

Nonsurgical Therapy. Chemotherapy and radiation therapy are used together when there are positive margins, bone erosion, or positive lymph nodes. Chemotherapeutic agents used include 5-fluorouracil (5-FU), methotrexate, cisplatin (Platinol), carboplatin (Paraplatin), paclitaxel (Taxol), docetaxel (Taxotere), cetuximab (Erbitux), and bleomycin (Blenoxane). Combination drug therapies are also used.[8] (Chemotherapy is discussed in Chapter 16.) Brachytherapy with implantations of radioactive seeds may be used to treat early-stage oral cancer.

Palliative treatment is often the best management when the prognosis is poor, the cancer is inoperable, or the patient decides against surgery. Palliation aims to treat the symptoms and make the patient more comfortable. If it becomes difficult for the patient to swallow, a gastrostomy tube may be inserted to allow for adequate nutritional intake. (Enteral nutrition is discussed in Chapter 40.) Analgesic medication should be given freely. Frequent suctioning of the oral cavity is necessary when swallowing becomes difficult. (Other palliative and end-of-life nursing measures are discussed in Chapter 10.)

Nutritional Therapy. Because of depression, alcoholism, or presurgery radiation treatment, patients may be malnourished before surgery. A percutaneous endoscopic gastrostomy (PEG) placement may be considered before radiation treatment or surgery. After radical neck surgery, the patient may be unable to orally ingest nutrients because of mucositis, swelling, location of sutures, or difficulty swallowing. Parenteral fluids are given for the first 24 to 48 hours. After this time, enteral nutrition is given via an NG, gastrostomy, or nasointestinal tube. (PEG and parenteral and enteral feedings are discussed in Chapter 40.) Cervical esophagostomy and pharyngostomy have also been used.

Observe for feeding tolerance and adjust the amount, time, and formula if nausea, vomiting, diarrhea, or distention occurs. Give small amounts of water when the patient can swallow. Observe for choking. Suctioning may be necessary to prevent aspiration.

NURSING MANAGEMENT ORAL CANCER

NURSING ASSESSMENT

Subjective and objective data to obtain from a patient with oral cancer are presented in Table 42-6.

TABLE 42-6 NURSING ASSESSMENT

Oral Cancer

Subjective Data

Important Health Information

Past health history: Recurrent oral herpetic lesions, human papillomavirus (HPV) infection or vaccination, syphilis, exposure to sunlight

Medications: Immunosuppressants

Surgery or other treatments: Removal of prior tumors or lesions

Functional Health Patterns

Health perception–health management: Use of alcohol and tobacco, pipe smoking; poor oral hygiene

Nutritional-metabolic: Reductions in oral intake, weight loss; difficulty chewing food; increased salivation; intolerance to certain foods or temperatures of food

Cognitive-perceptual: Mouth or tongue soreness or pain, toothache, earache, neck stiffness, dysphagia, difficulty speaking

Objective Data

Integumentary

Indurated, painless ulcer on lip; painless neck mass

Gastrointestinal

Areas of thickening or roughness, ulcers, leukoplakia, or erythroplakia on the tongue or oral mucosa; limited movement of the tongue; increased salivation, drooling; slurred speech; foul breath odor

Possible Diagnostic Findings

Positive exfoliative smear cytology (microscopic examination of cells removed by scraping); positive biopsy

NURSING DIAGNOSES

Nursing diagnoses for the patient with oral cancer may include, but are not limited to, the following:

- Imbalanced nutrition: less than body requirements *related to* oral pain, difficulty chewing and swallowing, surgical resection, and radiation treatment
- Chronic pain *related to* the tumor, surgery, or radiation
- Anxiety *related to* diagnosis of cancer, uncertain future, potential for disfiguring surgery, potential for recurrence, and prognosis
- Ineffective health maintenance *related to* lack of knowledge of disease process and therapeutic regimen and unavailability of a support system

PLANNING

The overall goals are that the patient with carcinoma of the oral cavity will (1) have a patent airway, (2) be able to communicate, (3) have adequate nutritional intake to promote wound healing, and (4) have relief of pain and discomfort.

NURSING IMPLEMENTATION

You have a significant role in early detection and treatment of oral cancer. Identify patients at risk (see Table 42-4) and provide information regarding predisposing factors. Inform the patient who smokes about smoking cessation programs available in the community. Warn adolescents and teenagers about the danger of using snuff or chewing tobacco. (Smoking cessation is discussed in Chapter 11 and Tables 11-4 to 11-6.)

Because early detection of oral cancer is important, teach the patient to report unexplained pain or soreness of the mouth, unusual bleeding, dysphagia, sore throat, voice changes, or swelling or lump in the neck. Refer any individual with an ulcerative lesion that does not heal within 2 to 3 weeks to a health care provider.

Preoperative care for the patient who will have a radical neck dissection involves consideration of the patient's physical and psychosocial needs. Physical preparation is the same as that for any major surgery, with special emphasis on oral hygiene. Explanations and emotional support should include information on postoperative communication and feeding. Explain the surgical procedure, and ensure that the patient understands the information. Radical neck dissection and related nursing management are discussed in Chapter 27 and eNursing Care Plan 27-2.

EVALUATION

The expected outcomes are that the patient with oral cancer will

- Have no respiratory complications
- Be able to communicate
- Maintain an adequate nutritional intake to promote wound healing
- Experience minimal pain and discomfort with eating, drinking, and talking

ESOPHAGEAL DISORDERS

GASTROESOPHAGEAL REFLUX DISEASE

Gastroesophageal reflux disease (GERD) is a chronic symptom of mucosal damage caused by reflux of stomach acid into the lower esophagus. GERD is not a disease but a syndrome. GERD is the most common upper GI problem. Approximately 10% to 20% of the U.S. population experience GERD symptoms (heartburn or regurgitation) at least once a week.[9]

HEALTHY PEOPLE

Health Impact of Good Oral Hygiene

- Improves quality of life
- Lowers risk of teeth loss
- Reduces pain and disability
- Decreases cost of care needed from dental professionals
- Assists in early detection of oral and craniofacial cancers
- Decreases risk of developing periodontal disease, gingivitis, and dental caries

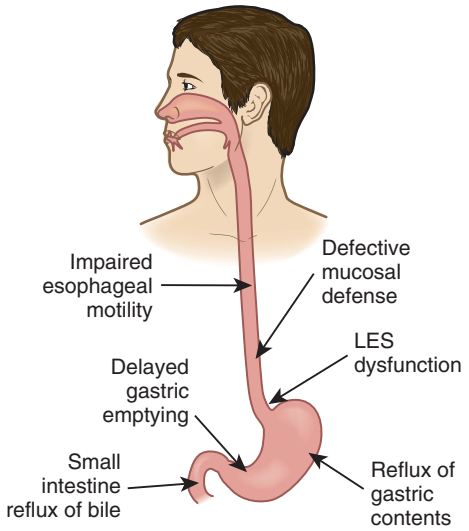

FIG. 42-2 Factors involved in the pathogenesis of gastroesophageal reflux disease (GERD). *LES,* Lower esophageal sphincter.

Etiology and Pathophysiology

GERD has no one single cause (Fig. 42-2). GERD results when the defenses of the esophagus are overwhelmed by the reflux of acidic gastric contents into the esophagus. Gastric HCl acid and pepsin secretions that reflux cause esophageal irritation and inflammation *(esophagitis).* If the refluxate contains intestinal proteolytic enzymes (e.g., trypsin) and bile, this further irritates the esophageal mucosa. The degree of inflammation depends on the amount and composition of the gastric reflux and on the esophagus's mucosal defense mechanisms.

One of the primary etiologic factors in GERD is an incompetent LES. Under normal conditions, the LES acts as an antireflux barrier. An incompetent LES lets gastric contents move from the stomach to the esophagus when the patient is supine or has an increase in intraabdominal pressure.

Decreased LES pressure can be due to certain foods (e.g., caffeine, chocolate, peppermint) and drugs (e.g., anticholinergics). Obesity is a risk factor for GERD, although the specific mechanism remains to be determined.[10] In an obese person the intraabdominal pressure is increased, which can exacerbate GERD. Cigarette and cigar smoking can also contribute to GERD. A common cause of GERD is a hiatal hernia, which is discussed in the next section.

Clinical Manifestations

The symptoms of GERD vary from person to person. The persistence of mild symptoms (i.e., more than twice a week) or moderate to severe symptoms once a week is considered GERD.

TABLE 42-7 FACTORS AFFECTING LOWER ESOPHAGEAL SPHINCTER PRESSURE

Increase Pressure
- bethanechol (Urecholine)
- metoclopramide (Reglan)

Decrease Pressure
- Alcohol
- Anticholinergics
- Chocolate (theobromine)
- Fatty foods
- Nicotine
- Peppermint, spearmint
- Tea, coffee (caffeine)
- Drugs
  - β-Adrenergic blockers
  - Calcium channel blockers
  - diazepam (Valium)
  - morphine sulfate
  - Nitrates
  - progesterone
  - theophylline

Heartburn *(pyrosis)* is the most common clinical manifestation. Heartburn is a burning, tight sensation felt intermittently beneath the lower sternum and spreading upward to the throat or jaw. Heartburn may occur after ingestion of food or drugs that decrease the LES pressure or directly irritate the esophageal mucosa (Table 42-7). A health care provider should evaluate heartburn that occurs more than twice a week, is rated as severe, occurs at night and wakes a person from sleep, or is associated with dysphagia. Older adults who complain of recent onset of heartburn should receive medical evaluation.

Patients may also complain of dyspepsia. *Dyspepsia* is pain or discomfort centered in the upper abdomen (mainly in or around the midline as opposed to the right or left hypochondrium).

Regurgitation is a fairly common manifestation of GERD. It is often described as hot, bitter, or sour liquid coming into the throat or mouth. Hypersalivation (water brash) may also be reported.

An individual with GERD may also report respiratory symptoms, including wheezing, coughing, and dyspnea. Nocturnal discomfort and coughing can awaken the patient, resulting in disturbed sleep patterns. Otolaryngologic symptoms include hoarseness, sore throat, a *globus sensation* (sense of a lump in the throat), and choking.

GERD-related chest pain can mimic angina and is described as burning; squeezing; or radiating to the back, neck, jaw, or arms. Complaints of chest pain are more common in older adults with GERD. Unlike angina, GERD-related chest pain is relieved with antacids.

Complications

Complications of GERD are due to the direct local effects of gastric acid on the esophageal mucosa. **Esophagitis** (inflammation of the esophagus) is a common complication of GERD. Esophagitis with esophageal ulcerations is shown in Fig. 42-3. Repeated esophagitis may lead to scar tissue formation, stricture, and ultimately dysphagia.

Another complication of chronic GERD is **Barrett's esophagus** (esophageal metaplasia). (*Metaplasia* is the reversible change from one type of cell to another type and is generally caused by some sort of abnormal stimulus.) In Barrett's esophagus the flat epithelial cells in the distal esophagus change to columnar epithelial cells. These cell changes are thought to be due primarily to GERD. However, people with no history of reflux symptoms can develop Barrett's esophagus.

Barrett's esophagus is considered a precancerous lesion that increases the patient's risk for esophageal adenocarcinoma.

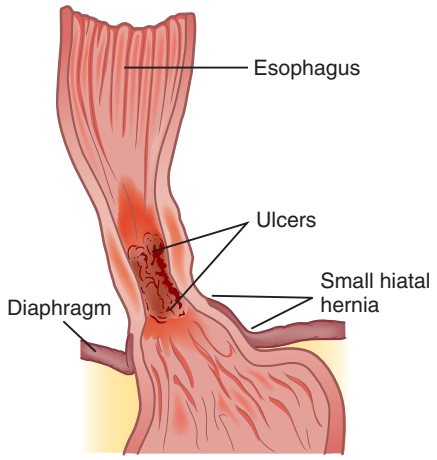

FIG. 42-3 Esophagitis with esophageal ulcerations.

Approximately 5% to 15% of patients with chronic reflux have Barrett's esophagus.[11] Compared with whites, African Americans and Asians are at lower risk for Barrett's esophagus. Because patients with evidence of metaplasia on an initial endoscopic examination are at risk for esophageal cancer, a surveillance endoscopy every 2 to 3 years is often recommended.[12]

Respiratory complications of GERD include cough, bronchospasm, laryngospasm, and cricopharyngeal spasm. These complications are due to irritation of the upper airway by gastric secretions. Asthma, chronic bronchitis, and pneumonia may develop as a result of aspiration into the respiratory system. Dental erosion, especially in the posterior teeth, may result from acid reflux into the mouth.[12]

Diagnostic Studies

GERD is usually diagnosed on the basis of symptoms and the patient's response to behavioral and drug therapies. Diagnostic tests are done when these therapies are refractory or when complications are suspected. Diagnostic studies performed to determine the cause of the GERD are shown in Table 42-8.

Endoscopy is useful in assessing the LES competence and the degree of inflammation (if present), potential scarring, and strictures. Biopsy and cytologic specimens can differentiate stomach or esophageal carcinoma from Barrett's esophagus. In addition, the degree of dysplasia (low grade versus high grade) is determined. Manometric studies measure pressure in the esophagus and LES and esophageal motility function. Ambulatory esophageal pH monitoring may be done for patients with refractory symptoms and no evidence of mucosal inflammation. Radionuclide tests can also detect reflux of gastric contents and the rate of esophageal clearance.

Collaborative Care

Most patients with GERD can successfully manage this condition through lifestyle modifications and drug therapy. These long-term approaches require patient teaching and adherence to therapies. When these therapies are ineffective, surgery is an option (see Table 42-8).

Lifestyle Modifications. Teach the patient with GERD to avoid factors that trigger symptoms (see Table 42-7). Give particular attention to diet and drugs that may affect the LES, acid secretion, or gastric emptying. Recommend weight reduction if the patient is overweight. A patient and caregiver teaching guide is provided in Table 42-9.

Encourage patients who smoke to stop. If needed, refer the patient to community resources for assistance in stopping smoking. (See Chapter 11 for additional information related to smoking cessation.) If stress seems to cause symptoms, discuss measures to cope with stress. (See Chapter 7 for stress management techniques.)

Nutritional Therapy. Diet does not cause GERD, but food can aggravate symptoms. No specific diet is necessary. Teach patients to avoid foods that decrease LES pressure, such as chocolate, peppermint, tomatoes, fatty foods, coffee, and tea (see Table 42-7), which predispose them to reflux. Also teach patients with GERD to avoid milk, especially at bedtime, since it increases gastric acid secretion. Small, frequent meals help prevent overdistention of the stomach. Saliva production can be increased by chewing gum and oral lozenges, which may help patients with mild symptoms of GERD.

Tell the patient to avoid late evening meals and nocturnal snacking, and to take fluids between rather than with meals to reduce gastric distention. Certain foods (e.g., tomato-based products, orange juice, cola, red wine) may irritate the esophagus.

Drug Therapy. Drug therapy for GERD focuses on decreasing volume and acidity of reflux, improving LES function, increasing esophageal clearance, and protecting the esophageal mucosa[13] (Table 42-10). Proton pump inhibitors (PPIs) and histamine (H_2)-receptor blockers are common and effective treatments for symptomatic GERD. The goal of HCl acid suppression treatment is to reduce the acidity of the gastric refluxate. Patients who are symptomatic with GERD but do not have evidence of esophagitis *(nonerosive GERD)* achieve symptom relief with PPIs and H_2-receptor blockers. The PPIs are more effective in healing esophagitis than H_2-receptor blockers. PPIs are also beneficial in decreasing the incidence of esophageal strictures, a complication of chronic GERD. Omeprazole is available as a prescription as well as an OTC preparation (Prilosec OTC) and in an immediate-release form (Zegerid).

TABLE 42-8 COLLABORATIVE CARE

Gastroesophageal Reflux Disease (GERD) and Hiatal Hernia

Diagnostic
- History and physical examination
- Upper GI endoscopy with biopsy and cytologic analysis
- Esophagram (barium swallow)
- Motility (manometry) studies
- pH monitoring (laboratory or 24 hr ambulatory)
- Radionuclide studies

Collaborative Therapy

Conservative
- Elevation of head of bed on 4- to 6-in blocks
- Avoid reflux-inducing foods (fatty foods, chocolate, peppermint)
- Avoid alcohol
- Reduce or avoid acidic pH beverages (colas, red wine, orange juice)
- Antacids
- Drug therapy (see Table 42-10)
  - Proton pump inhibitors
  - H_2-receptor blockers
  - Prokinetic drug therapy
  - Cholinergic drugs

Surgical
- Nissen fundoplication
- Toupet fundoplication

Endoscopic
- Intraluminal valvuloplasty
- Radiofrequency therapy

LES, Lower esophageal sphincter.

TABLE 42-9 PATIENT & CAREGIVER TEACHING GUIDE

Gastroesophageal Reflux Disease (GERD)

Include the following instructions when teaching the patient and caregiver about management of GERD.

1. Explain the rationale for a low-fat diet.
2. Encourage the patient to eat small, frequent meals to prevent gastric distention.
3. Explain the rationale for avoiding alcohol, smoking (causes an almost immediate, marked decrease in LES pressure), and beverages that contain caffeine.
4. Advise the patient to not lie down for 2-3 hr after eating, wear tight clothing around the waist, or bend over (especially after eating).
5. Have the patient avoid eating within 3 hr of bedtime.
6. Encourage the patient to sleep with head of bed elevated on 4- to 6-in blocks (gravity fosters esophageal emptying).
7. Provide information regarding drugs, including rationale for their use and common side effects.
8. Discuss strategies for weight reduction if appropriate.
9. Encourage patient and caregiver to share concerns about lifestyle changes and living with a chronic problem.

LES, Lower esophageal sphincter.

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

Are Proton Pump Inhibitors Associated With Increased Risk of Diarrhea?

Clinical Question

Among hospitalized patients (P), does the use of proton pump inhibitor drugs (I) increase the risk of *Clostridium difficile*–associated diarrhea (O)?

Best Available Evidence

Meta-analysis of case-control and cohort studies

Critical Appraisal and Synthesis of Evidence
- Twenty-three studies examined hospitalized patient medical records ($n = 300,000$) for proton pump inhibitor (PPI) exposure and confirmation of acute diarrhea due to *C. difficile.*
- Patients taking PPIs have a greater risk (65%) of *C. difficile*–associated diarrhea (CDAD).

Conclusion
- There is a significant positive association between PPIs and the incidence of CDAD.

Implications for Nursing Practice
- Advise patients taking PPIs of the risk for diarrhea and to contact their health care provider if it does not improve.
- Inform patients that CDAD symptoms include watery stool, abdominal pain, and fever.
- Institute infection control procedures in hospitalized patients suspected of having *C. difficile* infection.

TABLE 42-10 DRUG THERAPY

Gastroesophageal Reflux Disease (GERD) and Peptic Ulcer Disease (PUD)

Drug	Mechanism of Action	Side Effects
Proton Pump Inhibitors (PPIs) dexlansoprazole (Dexilant) esomeprazole (Nexium) lansoprazole (Prevacid) omeprazole (Prilosec) pantoprazole (Protonix) rabeprazole (AcipHex)	↓ HCl acid secretion by inhibiting the proton pump (H^+-K^+-ATPase) responsible for the secretion of H^+ ↓ Irritation of the esophageal and gastric mucosa	Headache, abdominal pain, nausea, diarrhea, vomiting, flatulence
Histamine (H_2)-Receptor Blockers cimetidine (Tagamet) famotidine (Pepcid) nizatidine (Axid) ranitidine (Zantac)	Blocks the action of histamine on the H_2 receptors to ↓ HCl acid secretion ↓ Conversion of pepsinogen to pepsin ↓ Irritation of the esophageal and gastric mucosa	Headache, abdominal pain, constipation, diarrhea
Prokinetic Agents metoclopramide (Reglan)	Blocks effect of dopamine ↑ Gastric motility and emptying Reduces reflux	CNS side effects ranging from anxiety to hallucinations Extrapyramidal side effects (tremor and dyskinesias similar to Parkinson's disease)
Antiulcer, Protectants sucralfate (Carafate)	Acts to form a protective layer and serves as a barrier against acid, bile salts, and enzymes in the stomach	Constipation
Cholinergic bethanechol (Urecholine)	↑ LES pressure, improves esophageal emptying, increases gastric emptying	Lightheadedness, syncope, flushing diarrhea, stomach cramps, dizziness
Antacids, Acid Neutralizers ***Single Substance*** aluminum carbonate (Basaljel) aluminum hydroxide (Amphojel) calcium carbonate (Tums, Titralac) magnesium oxide (MagOx) sodium bicarbonate (Alka-Seltzer) sodium citrate (Bicitra) ***Aluminum and Magnesium*** Gelusil, Maalox, Mylanta, Aludrox aluminum/magnesium trisilicate (Gaviscon)	Neutralizes HCl acid Taken 1-3 hr after meals and at bedtime	*Aluminum hydroxide:* Constipation, phosphorus depletion with chronic use *Calcium carbonate:* Constipation or diarrhea, hypercalcemia, milk-alkali syndrome, renal calculi *Magnesium preparations:* Diarrhea, hypermagnesemia *Sodium preparations:* Milk-alkali syndrome if used with large amounts of calcium; use with caution in patients on sodium restrictions
Prostaglandin (Synthetic) misoprostol (Cytotec)	Protects lining of stomach *Cytoprotective:* Increases production of gastric mucus and mucosal secretion of bicarbonate *Antisecretory:* ↓ HCl acid secretion	Abdominal pain, diarrhea, GI bleeding, uterine rupture if pregnant

LES, Lower esophageal sphincter.

Long-term use of PPIs has been associated with decreased bone density,[14] chronic hypochlorhydria, and increased risk of *Clostridium difficile* in hospitalized patients.[15] Long-term PPI use has also been associated with pneumonia.

DRUG ALERT: Proton Pump Inhibitors (PPIs)

- Long-term use or high doses of PPIs may increase the risk of fractures of hip, wrist, and spine.
- Lower doses or shorter duration of therapy should be considered.
- PPIs are associated with increased risk of *C. difficile* infection in hospitalized patients.

H_2-receptor blockers reduce symptoms and promote esophageal healing in 50% of patients. These drugs are available in OTC and prescription formulations. OTC preparations have lower drug dosages compared with prescription drugs. Some formulations include an H_2-receptor blocker plus antacid combination. For example, Pepcid Complete includes famotidine, calcium carbonate, and magnesium hydroxide. (Antihistamine drugs used to treat allergies are H_1-receptor blockers and have no effect on HCl acid secretion.)

Sucralfate (Carafate), an antiulcer drug, is used in some patients with GERD for its cytoprotective properties. Cholinergic drugs (e.g., bethanechol [Urecholine]) increase LES pressure, improve esophageal emptying in the supine position, and increase gastric emptying. However, cholinergic drugs also increase HCl acid secretion. Prokinetic (motility-enhancing) drugs (metoclopramide [Reglan]) promote gastric emptying and reduce the risk of gastric acid reflux (see Table 42-10) but are not used as primary therapies for GERD.

Antacids produce quick but short-lived relief of heartburn. They should be taken 1 to 3 hours after meals and at bedtime.

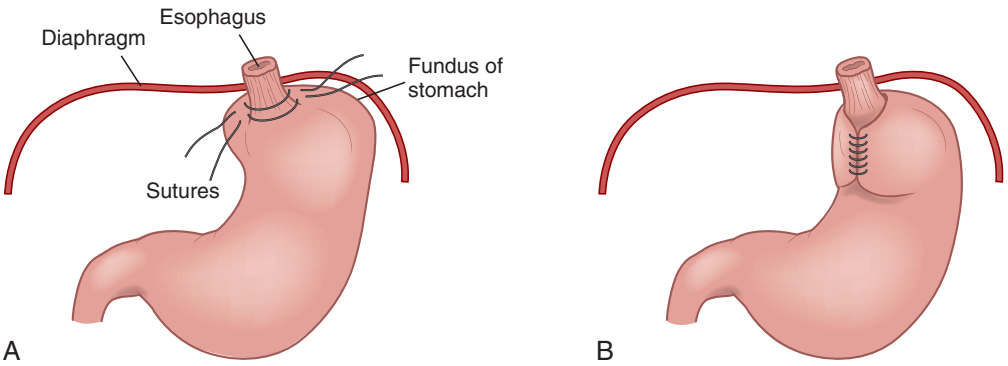

FIG. 42-4 Nissen fundoplication for repair of hiatal hernia. **A,** Fundus of stomach is wrapped around distal esophagus. **B,** The fundus is then sutured to itself.

Antacids with or without alginic acid (e.g., Gaviscon) may be useful in patients with mild, intermittent heartburn. However, in patients with moderate to severe or frequent symptoms or patients with documented esophagitis, antacids are not effective in relieving symptoms or healing lesions.

Surgical Therapy. Surgical therapy (*antireflux* surgery) is reserved for patients with complications of reflux, including esophagitis, intolerance of medications, stricture, Barrett's metaplasia, and persistence of severe symptoms. Most surgical procedures are performed laparoscopically. The goal of surgical interventions is to reduce reflux by enhancing the integrity of the LES. In these procedures the fundus of the stomach is wrapped around the lower portion of the esophagus to reinforce and repair the defective barrier. Laparoscopically performed Nissen and Toupet fundoplications are common antireflux surgeries (Fig. 42-4).

The LINX Reflux Management System is used for patients who continue to have symptoms despite maximum medical management. In this system, titanium beads with a magnetic core are strung together and implanted laparoscopically into the LES. Once implanted, the ring provides strength (augmentation) to a weakened LES. Under resting, nonswallowing conditions the ring tightens due to the magnetic attraction of the beads. When the individual swallows, the force of pressure associated with the movement of the fluids or foods overwhelms the magnetic forces such that the fluid or food passes to the stomach. Adverse events experienced with the system include difficulty swallowing, vomiting, nausea, chest pain, and pain when swallowing food.

Endoscopic Therapy. Alternatives to surgical therapy include endoscopic mucosal resection (EMR), photodynamic therapy, cryotherapy, and radiofrequency ablation (image-guided technique that kills cells through heating). For patients with high-grade dysplasia, EMR can also be used as a diagnostic test to obtain biopsy samples. The results of the biopsy can determine whether adenocarcinoma is present.

NURSING MANAGEMENT GASTROESOPHAGEAL REFLUX DISEASE

Nursing care for the patient with acute symptoms of GERD consists of encouraging the patient to follow the necessary regimen. The head of the bed is elevated to approximately 30 degrees. This can be done using pillows or with 4- to 6-in blocks under the bed. For 2 to 3 hours after a meal the patient should not be supine. Teach the patient to avoid food and activities that cause reflux (e.g., late-night eating). Instruct patients to contact their health care provider if symptoms persist.

The patient on a PPI needs to take medication before the first meal of the day. Instruct the patient about possible medication side effects (see Table 42-10). Tell the patient on a prescription H_2-receptor agent to take the medication as prescribed and not to stop without checking with his or her health care provider.

Postoperative care focuses on prevention of respiratory complications, maintenance of fluid and electrolyte balance, and prevention of infection. If an open high abdominal incision is used, respiratory complications can occur. Respiratory assessment includes respiratory rate and rhythm, pulse rate and rhythm, and signs of pneumothorax (e.g., dyspnea, chest pain, cyanosis). Deep breathing is essential to fully expand the lungs. Because most procedures are performed laparoscopically, the risk of respiratory complications is reduced. The laparoscopic fundoplication is often performed as an outpatient procedure. However, patients at risk for complications, including those with prior upper abdominal surgeries or co-morbidities (e.g., cardiac disease, obesity), may be hospitalized after the procedure. During the postoperative phase, patients require medications to prevent nausea and vomiting and to control pain. A small percentage of patients experience complications, including gastric or esophageal injury, splenic injury, pneumothorax, perforation, bleeding, infection, and pneumonia.

When peristalsis returns, only fluids are given initially. Measure and record the intake and output. Solids are added gradually with the goal of resuming a normal diet. Teach the patient to avoid foods that are gas forming to prevent gastric distention and to chew food thoroughly.

After surgery, reflux symptoms should decrease. However, the recurrence rate may range from 10% to 30% over a 20-year period. In the first month after surgery the patient may report mild dysphagia caused by edema, but it should resolve. Instruct the patient to report persistent symptoms such as heartburn and regurgitation.

HIATAL HERNIA

Hiatal hernia is herniation of a portion of the stomach into the esophagus through an opening, or hiatus, in the diaphragm. It is also referred to as diaphragmatic hernia and esophageal hernia. It is the most common abnormality found on x-ray examination of the upper GI tract. Hiatal hernias are common in older adults and occur more often in women than in men.

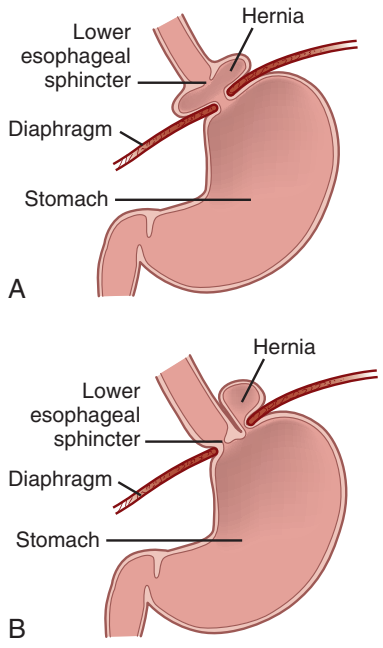

FIG. 42-5 **A,** Sliding hiatal hernia. **B,** Rolling or paraesophageal hernia.

Hiatal hernias are classified into the following two types (Fig. 42-5):

1. *Sliding:* The junction of the stomach and the esophagus is above the diaphragm, and a part of the stomach slides through the hiatal opening in the diaphragm. This occurs when the patient is supine, and the hernia usually goes back into the abdominal cavity when the patient is standing upright. This is the most common type of hiatal hernia.
2. *Paraesophageal,* or *rolling:* The esophagogastric junction remains in the normal position, but the fundus and the greater curvature of the stomach roll up through the diaphragm, forming a pocket alongside the esophagus. Acute paraesophageal hernia is a medical emergency.

Etiology and Pathophysiology

Many factors contribute to the development of hiatal hernia. Structural changes, such as weakening of the muscles in the diaphragm around the esophagogastric opening, occur with aging. Factors that increase intraabdominal pressure, including obesity, pregnancy, ascites, tumors, intense physical exertion, and heavy lifting on a continual basis, may also predispose patients to development of a hiatal hernia.

Clinical Manifestations and Complications

Some individuals with hiatal hernia are asymptomatic. When present, signs and symptoms of hiatal hernia are similar to those described for GERD on pp. 931-932.

Complications that may occur with hiatal hernia include GERD, esophagitis, hemorrhage from erosion, stenosis (narrowing of the esophagus), ulcerations of the herniated portion of the stomach, strangulation of the hernia, and regurgitation with tracheal aspiration.

Diagnostic Studies

An esophagram (barium swallow) may show the protrusion of gastric mucosa through the esophageal hiatus. Endoscopic visualization of the lower esophagus provides information on the degree of mucosal inflammation or other abnormalities. Other tests are listed in Table 42-8.

ETHICAL/LEGAL DILEMMAS

Guardianship

Situation

B.G., a 32-yr-old man, has been institutionalized most of his life for profound developmental disabilities. He is now hospitalized with aspiration-related pneumonia for the fourth time in the last year. His health care provider believes that a feeding tube would solve the problem of aspiration. The family believes his life span should not be extended by artificial means and refuses to give consent. The hospital is considering seeking a court-appointed guardian because the family is not acting in B.G.'s best interests.

Ethical/Legal Points for Consideration

- Legal decisions involving guardianship of an incapacitated individual are usually complex and not easy to make. Wide variations exist from state to state about the definitions of terms and scope of guardianship.
- Wide variation also exists in the circumstances that cause an individual to be incapacitated. These include the degree of impairment, when it started, the patient's ability now or in the past to state his or her own preferences, financial assets related to inheritance that may bias the preferences of the disagreeing parties, the relationship of the current question or issue to end-of-life decision making, and whether withdrawal of treatment is in the best interest of the individual.
- Two standards are used in decision making for incompetent patients: substituted judgment and best interest. *Substituted judgment* is basing the decision on what previously competent patients would have decided for themselves. The *best interest standard* involves making the best decision possible under the circumstances using experiences from the patient's life that are meaningful or bring satisfaction to the patient (if known).
- In this situation, B.G. may never have had the capacity to make his preference known about tube feeding. Using the best interest standard, arguments would have to be made about which alternative poses the least risk to the patient.
- As a nurse, you may be the only professional who can provide an expert opinion on the safety of tube feeding vs. the current practice (oral feedings). This incorporates both the patient advocacy dimension of your role and the best practices dimensions of evidence-based practice.

Discussion Questions

1. What are your thoughts and beliefs about the two opposing positions of preserving life in all circumstances vs. maintaining an adequate quality of life?
2. In your opinion, who is in the best position to define quality of life for B.G.?

NURSING AND COLLABORATIVE MANAGEMENT HIATAL HERNIA

Conservative therapy of hiatal hernia is similar to that described for GERD (pp. 932-935). Teach the patient to reduce intraabdominal pressure by eliminating constricting garments and avoiding lifting and straining.

Surgical approaches to hiatal hernias can include reduction of the herniated stomach into the abdomen, *herniotomy* (excision of the hernia sac), *herniorrhaphy* (closure of the hiatal defect), an antireflux procedure, and *gastropexy* (attachment of the stomach subdiaphragmatically to prevent reherniation). The goals are to reduce the hernia, provide an acceptable LES pressure, and prevent movement of the gastroesophageal junction. Antireflux surgeries for hiatal hernia are laparoscopically per-

formed Nissen and Toupet techniques (see Fig. 42-4). A thoracic or an open abdominal approach may be done, depending on the patient.

GERONTOLOGIC CONSIDERATIONS

GASTROESOPHAGEAL REFLUX DISEASE AND HIATAL HERNIA

The incidence of hiatal hernia and GERD increases with age. Hiatal hernia is associated with weakening of the diaphragm, obesity, kyphosis, or other factors (e.g., wearing girdles) that increase intraabdominal pressure. Medications commonly taken by older patients decrease LES pressure (e.g., nitrates, calcium channel blockers, antidepressants). Other agents such as nonsteroidal antiinflammatory drugs (NSAIDs) and potassium can irritate the esophageal mucosa *(medication-induced esophagitis)*.

Some older adults with hiatal hernia and GERD are asymptomatic or have less severe symptoms. The first indications may include esophageal bleeding secondary to esophagitis or respiratory complications (e.g., aspiration pneumonia) related to aspiration of gastric contents.

The clinical course and management of GERD and hiatal hernia in the older adult are similar to those for the younger adult. Changes in lifestyle, including eliminating dietary factors (such as caffeine-containing beverages and chocolate) and elevating the head of the bed on blocks, may be challenging for the older adult.

Laparoscopic procedures reduce the risk of surgical repair. An older patient with cardiovascular and pulmonary problems may not be a good candidate for surgical intervention.

ESOPHAGEAL CANCER

Esophageal cancer (malignant neoplasm of the esophagus) is not common. However, the rates are increasing. Annually in the United States approximately 17,460 new cases of esophageal cancer are diagnosed and 15,070 deaths occur from esophageal cancer.[5] The 5-year survival rate is 37% for localized cancer and 18% for regional cancer.

The majority of esophageal cancers are adenocarcinomas, with the remainder being squamous cell tumors. Adenocarcinomas arise from the glands lining the esophagus and resemble cancers of the stomach and small intestine. The incidence of esophageal cancer increases with age, with those between 70 and 84 at greatest risk. There is a higher incidence of esophageal cancer in non-Hispanic white men and Alaska Natives compared with other ethnic groups. The incidence of esophageal cancer is higher in men than in women.

Etiology and Pathophysiology

The cause of esophageal cancer is unknown. Several important risk factors include Barrett's metaplasia, smoking, excessive alcohol intake, and obesity. For example, current smoking or a history of smoking are associated with a 2-fold higher risk of esophageal cancer. Patients with injury to the esophageal mucosa (e.g., from occupational exposure) are at greater risk. *Achalasia,* a condition in which there is delayed emptying of the lower esophagus, is associated with squamous cell cancer.

Most esophageal tumors are located in the middle and lower portions of the esophagus. The malignant tumor usually appears as an ulcerated lesion and has often advanced by the time the patient experiences symptoms. The tumor may penetrate the muscular layer and even extend outside the wall of the esophagus. Obstruction of the esophagus occurs in the later stages.

Clinical Manifestations and Complications

The onset of symptoms is usually late relative to tumor growth. The majority of patients have advanced disease at diagnosis. Progressive dysphagia is the most common symptom and may be described as a substernal feeling as if food is not passing. Initially the dysphagia occurs only with meat, then with soft foods, and eventually with liquids.

Pain develops late. It is described as occurring in the substernal, epigastric, or back areas and usually increases with swallowing. The pain may radiate to the neck, jaw, ears, and shoulders. If the tumor is in the upper third of the esophagus, symptoms such as sore throat, choking, and hoarseness may occur. Weight loss is fairly common. When esophageal stenosis (narrowing) is severe, regurgitation of blood-flecked esophageal contents is common.

Hemorrhage occurs if the cancer erodes through the esophagus and into the aorta. Esophageal perforation with fistula formation into the lung or trachea sometimes develops. The tumor may enlarge enough to cause esophageal obstruction. The cancer spreads via the lymph system, with the liver and the lung being common sites of metastasis.

Diagnostic Studies

Endoscopic biopsy is necessary to make a definitive diagnosis of carcinoma by identification of malignant cells. Endoscopic ultrasonography (EUS) is an important tool used to stage esophageal cancer. Esophagram (barium swallow) may show narrowing of the esophagus at the tumor site (Table 42-11).

Collaborative Care

The treatment of esophageal cancer depends on the location of the tumor and whether invasion or metastasis has occurred. Esophageal cancer has a poor prognosis, mainly because it is often not diagnosed until the disease is advanced. The best

TABLE 42-11 COLLABORATIVE CARE

Esophageal Cancer

Diagnostic
- History and physical examination
- Endoscopy of esophagus with biopsy
- Endoscopic ultrasonography
- Esophagram (barium swallow)
- Bronchoscopy
- CT, MRI

Collaborative Therapy
- Surgery
  - Esophagectomy
  - Esophagogastrostomy
  - Esophagoenterostomy
- Endoscopic procedures
  - Photodynamic therapy
  - Endoscopic mucosal resection
- Radiation therapy
- Chemotherapy
- Palliative treatment
  - Dilation
  - Stent or prosthesis
  - Laser therapy
  - Gastrostomy

results are obtained with a multimodal approach, including surgery, endoscopic ablation, chemotherapy, and radiation therapy. Depending on the location and cancer spread, only chemotherapy and radiation may be used.

Surgery. The types of surgical procedures done are (1) removal of part or all of the esophagus *(esophagectomy)* with use of a Dacron graft to replace the resected part, (2) resection of a portion of the esophagus and anastomosis of the remaining portion to the stomach *(esophagogastrostomy),* and (3) resection of a portion of the esophagus and anastomosis of a segment of colon to the remaining portion *(esophagoenterostomy).* The surgical approaches may be open (thoracic, abdominal incision) or laparoscopic.

Minimally invasive esophagectomy (e.g., laparoscopic vagal nerve–sparing surgery) is being performed more frequently. It has the advantage of using smaller incisions, decreasing intensive care unit (ICU) and hospital stays, and producing fewer pulmonary complications.

Endoscopic Procedures. Endoscopic approaches using photodynamic and/or laser therapy can be performed. In photodynamic therapy, porfimer sodium (Photofrin), which is a photosensitizer, is injected IV. The porfimer is absorbed by most tissues but selectively retained to a greater degree by neoplastic tissue. The light (activator) is transmitted via a fiber passed through the endoscope. Warn patients to avoid direct sunlight for up to 4 weeks after the procedure. Other endoscopic procedures include EMR.

Radiation and Chemotherapy. Most patients with newly diagnosed esophageal cancer have local and advanced disease. Treatment includes chemotherapy with or without radiation therapy. Concurrent radiation and chemotherapy are administered for palliation of symptoms, especially dysphagia, and to increase survival. In some patients, treatment is started before surgery is performed.

Currently, no standard single-agent or combination drug therapy is recommended for esophageal cancer. Single-agent chemotherapeutic agents include bleomycin, mitomycin (Mutamycin), methotrexate, paclitaxel, docetaxel, and irinotecan (Camptosar). Combination regimens include ECF (epirubicin [**E**llence], **c**isplatin, 5-**f**luorouracil [5-FU]), and taxane- and irinotecan-based combinations. Cisplatin in combination with newer fluoropyrimidine such as tegafur-uracil (Uftoral) (tegafur is a 5-FU prodrug) is also used.

Palliative therapy consists of restoration of the swallowing function and maintenance of nutrition and hydration. Dilation, stent placement, or both can relieve obstruction. Self-expandable metal stents are available with features to prevent stent migration and tumor ingrowth. Dilation is done with various types of dilators. Dilation often relieves dysphagia and allows for improved nutrition. Endoscopic placement of stents or expandable stents may help when dilation is no longer effective.[16] This allows food and liquid to pass through the stenotic segment of the esophagus. Stents may be placed before surgery to improve the patient's nutritional status.

Endoscopic laser therapy of the tumor may be used in combination with dilation. Obstruction recurs as the tumor grows, but laser therapy can be repeated. Sometimes these procedures are combined with radiation therapy. Other measures for palliation include gastrostomy or esophagostomy tube placement for nutritional support and pain management.

Nutritional Therapy. After esophageal surgery, parenteral fluids are given. A jejunostomy feeding tube may be used depending on the type of surgery (e.g., esophagogastrectomy) performed. A swallowing study is often given before the patient is allowed to have oral fluids. When fluids are permitted, water (30 to 60 mL) is given hourly, with gradual progression to small, frequent, bland meals. The patient should be in an upright position to prevent regurgitation of the fluid. With tube feeding, observe the patient for signs of intolerance to the feeding or leakage of the feeding into the mediastinum. Symptoms that indicate leakage are pain, increased temperature, and dyspnea. A gastrostomy tube may be placed to feed the patient. (Enteral nutrition is discussed in Chapter 40.)

NURSING MANAGEMENT ESOPHAGEAL CANCER

NURSING ASSESSMENT

Ask the patient about a history of GERD, hiatal hernia, achalasia, Barrett's esophagus, and tobacco and alcohol use. Assess the patient for progressive dysphagia and *odynophagia* (burning, squeezing pain while swallowing). Ask about the type of substances (e.g., meats, soft foods, liquids) that cause dysphagia. Also assess the patient for pain (substernal, epigastric, or back areas), choking, heartburn, hoarseness, cough, anorexia, weight loss, and regurgitation.

NURSING DIAGNOSES

Nursing diagnoses for the patient with esophageal cancer include, but are not limited to, the following:

- Chronic pain *related to* the compression of tumor on surrounding tissues, esophageal stenosis
- Imbalanced nutrition: less than body requirements *related to* dysphagia, odynophagia, weakness, chemotherapy, and radiation therapy
- Ineffective health maintenance *related to* lack of knowledge of disease process and treatment, lack of a support system, and chronic debilitating disease
- Anxiety and grieving *related to* diagnosis of cancer, uncertain future, and poor prognosis

PLANNING

The overall goals are that the patient with esophageal cancer will (1) have relief of symptoms, including pain and dysphagia; (2) achieve optimal nutritional intake; (3) understand the prognosis of the disease; and (4) experience a quality of life appropriate to disease progression.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Counsel the patient with GERD, Barrett's esophagus, or hiatal hernia about the importance of regular follow-up evaluation. Health counseling should focus on elimination of smoking and excessive alcohol intake, as well as other risk factors for GERD (see Table 42-7). Maintenance of good oral hygiene and dietary habits (e.g., intake of fresh fruits and vegetables) is important. Encourage patients to seek medical attention for any esophageal problems, especially dysphagia.

ACUTE INTERVENTION

Preoperative Care. In addition to general preoperative teaching and preparation, pay particular attention to the patient's nutritional needs. Many patients are poorly nourished because of the inability to ingest adequate amounts of food and fluids before surgery. A high-calorie, high-protein diet is recommended. Some patients require a liquid form of this diet. Some patients may need IV fluid replacement or parenteral nutrition. Instruct the patient and caregiver on how to keep an intake and

output record and assess for signs of fluid and electrolyte imbalance. Some treatment protocols necessitate preoperative radiation and chemotherapy.

Meticulous oral care is essential. Cleanse the mouth thoroughly, including the tongue, gingivae, and teeth or dentures. It may be necessary to use swabs or a gauze pad and to scrub the mouth, including the tongue. Milk of magnesia with mineral oil helps remove crust formation.

Teaching should include information about chest tubes (if an open thoracic approach is used), IV lines, NG tubes, pain management, gastrostomy or jejunostomy feeding, turning, coughing, and deep breathing. (General preoperative care is discussed in Chapter 18.)

Postoperative Care. The patient usually has an NG tube in place and may have bloody drainage for 8 to 12 hours. The drainage gradually changes to greenish yellow. Assessment of the drainage, maintenance of the tube, and oral and nasal care are nursing responsibilities. Do not reposition the NG tube or reinsert it without consulting the surgeon.

Because of the location of the surgery and the patient's general condition, emphasize prevention of respiratory complications. Turning and deep breathing should be done every 2 hours. Use of an incentive spirometer helps to prevent respiratory complications.

Cardiac dysrhythmias may result from the proximity of the pericardium to the surgical site. Additional complications that can occur after esophagectomy include esophageal anastomotic leaks, fistula formation, interstitial pulmonary edema, and acute respiratory distress related to the disruption of the mediastinal lymph nodes.

Position the patient in a semi-Fowler's or Fowler's position to prevent reflux and aspiration of gastric secretions. When the patient can drink fluids or eat, maintain the upright position for at least 2 hours after eating to assist with gastric emptying.

AMBULATORY AND HOME CARE. Many patients require long-term follow-up care after surgery for esophageal cancer. The patient may undergo chemotherapy and radiation treatment after surgery. Encourage and assist the patient in maintaining adequate nutrition. A permanent feeding gastrostomy may be required. The patient usually has fears and anxieties about a diagnosis of cancer. Know what the health care provider has told the patient regarding the prognosis and then provide appropriate counseling.

Referral to a palliative care or home health nurse may be needed. (See Chapter 16 for the care of the cancer patient and Chapter 10 for a discussion of palliative and end-of-life care.)

EVALUATION

The expected outcomes are that the patient with esophageal cancer will

- Maintain a patent airway
- Have relief of pain
- Be able to swallow comfortably and consume adequate nutritional intake
- Understand the prognosis of the disease
- Experience a quality of life appropriate to disease progression

OTHER ESOPHAGEAL DISORDERS

Eosinophilic Esophagitis

Eosinophilic esophagitis (EE) is characterized by swelling of the esophagus caused by an infiltration of *eosinophils.* People with EE frequently have a personal or family history of other allergic diseases. The most common food triggers are milk, egg, wheat, rye, and beef. Environmental allergens, such as pollens, molds, cat, dog, and dust mite allergens, may be involved in the development of EE.

Clinical manifestations include severe heartburn, difficulty swallowing, food impaction in the esophagus, nausea, vomiting, and weight loss. The diagnosis is based on the symptoms and biopsy findings of eosinophils infiltrating the esophageal tissue obtained from endoscopy.

Allergy skin testing helps to determine the person's allergens. A trial of avoidance of the foods to which the person has positive allergy tests is the initial form of treatment for EE. A variety of treatment approaches, including acid suppression (see Table 42-10), corticosteroids, and endoscopic dilation, can be used alone or in combination.

Corticosteroids are frequently used to treat EE when avoidance of allergic triggers does not relieve symptoms. Corticosteroids may be used orally (prednisone) or as a topical therapy, such as inhaled corticosteroids (e.g., fluticasone [Flovent]). In asthma, where fluticasone is typically used, it is inhaled. In EE it is swallowed, and this results in the delivery of the drug directly to the esophagus.

Esophageal Diverticula

Esophageal diverticula are saclike outpouchings of one or more layers of the esophagus. They occur in three main areas: (1) above the upper esophageal sphincter *(Zenker's diverticulum),* which is the most common location; (2) near the esophageal midpoint (traction diverticulum); and (3) above the LES (epiphrenic diverticulum) (Fig. 42-6). Pharyngeal pouches (Zenker's diverticula) occur most commonly in individuals over 60 years.

Typical symptoms include dysphagia, regurgitation, chronic cough, aspiration, and weight loss. The patient frequently complains of tasting sour food and smelling a foul odor caused by the stagnant food. Complications include malnutrition, aspiration, and perforation. Endoscopy or barium studies can easily establish a diagnosis.

There is no specific treatment for esophageal diverticula. Some patients find that they can empty the pocket of food that collects by applying pressure at a point on the neck. The diet may need to be limited to foods that pass more readily (e.g., blenderized foods). Treatment via an endoscopic or open approach may be necessary if nutrition is disrupted. Treatment

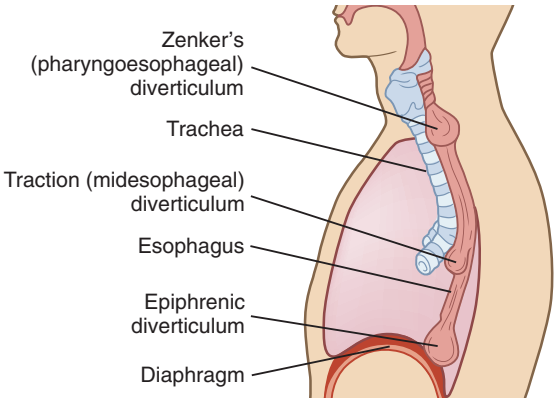

FIG. 42-6 Possible sites for esophageal diverticula. These hollow outpouchings may occur just above the upper esophageal sphincter (Zenker's, the most common type of pulsion diverticulum), near the midpoint of the esophagus (traction), and just above the lower esophageal sphincter (epiphrenic).

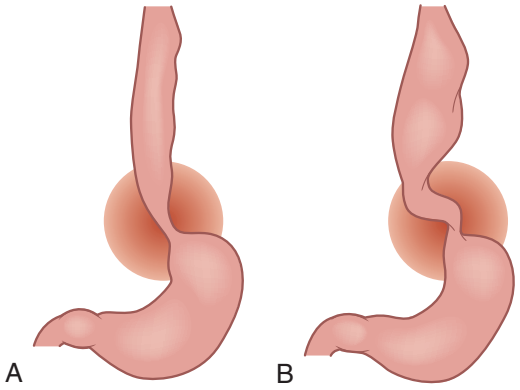

FIG. 42-7 Esophageal achalasia. **A,** Early stage, showing tapering of lower esophagus. **B,** Advanced stage, showing dilated, tortuous esophagus.

by endoscopic stapling diverticulotomy or diverticulostomy is associated with decreased complications compared with the open approaches. The most serious complication of this treatment is perforation of the esophagus.

Esophageal Strictures

The most common cause of *esophageal strictures* (or narrowing) is chronic GERD. The ingestion of strong acids or alkalis, external beam radiation, and surgical anastomosis can also create strictures. Trauma such as throat lacerations and gunshot wounds may also lead to strictures as a result of scar formation. The strictures can result in dysphagia, regurgitation, and ultimately weight loss.

Strictures can be dilated endoscopically using mechanical *bougies* (dilating instruments) or balloons. The dilation may be performed with or without endoscopy, or with fluoroscopy. Surgical excision with anastomosis is sometimes necessary. The patient may have a temporary or permanent gastrostomy.

Achalasia

In **achalasia,** peristalsis of the lower two thirds (smooth muscle) of the esophagus is absent. Achalasia is a rare, chronic disorder. With achalasia the pressure in the LES increases along with incomplete relaxation. Obstruction of the esophagus at or near the diaphragm occurs. Food and fluid accumulate in the lower esophagus. The result of this condition is dilation of the lower esophagus proximal to (above) the tapering affected segment of the lower esophagus (Fig. 42-7). There is a selective loss of inhibitory neurons, resulting in unopposed contraction of the LES.

The onset of achalasia is usually insidious. Dysphagia is the most common symptom and occurs with both liquids and solids. Patients may report a globus sensation and/or substernal chest pain (similar to angina pain) that occurs during or immediately after a meal. About a third of the patients experience nocturnal regurgitation. *Halitosis* (foul-smelling breath) and the inability to eructate (belch) are other symptoms. Patients with achalasia also report symptoms of GERD and regurgitation of sour-tasting food and liquids, especially when they are lying down. Weight loss is typical.

Diagnosis is made with esophagram (barium swallow), manometric evaluation (high-resolution manometry), and/or endoscopic evaluation. The exact cause of achalasia is not known, so treatment focuses on symptom management. The goals of treatment are to relieve dysphagia and regurgitation, improve esophageal emptying by disrupting the LES, and prevent development of megaesophagus (enlargement of the lower esophagus).

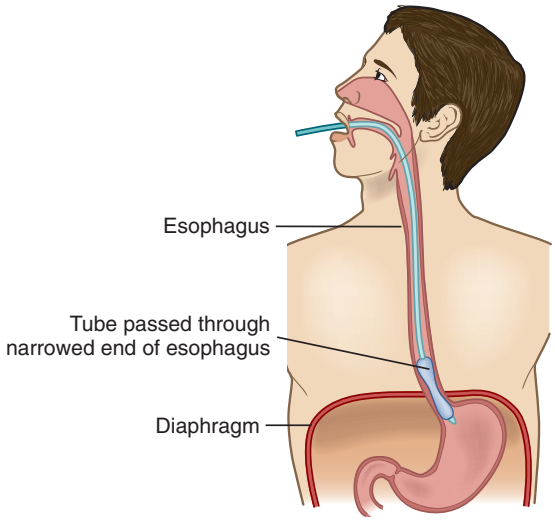

FIG. 42-8 Pneumatic dilation attempts to treat achalasia by maintaining an adequate lumen and decreasing lower esophageal sphincter (LES) tone.

Endoscopic pneumatic dilation is done as an outpatient procedure. The LES muscle is disrupted from within using balloons of progressively larger diameter (3.0, 3.5, and 4.0 cm) (Fig. 42-8). If this is ineffective, then a surgical procedure, Heller myotomy, is done laparoscopically. In this procedure the LES is surgically disrupted (myotomy). Because GERD with esophagitis and stricture is a common complication, the patient often has antireflux surgery performed at the same time. The patient can usually return to work 1 to 2 weeks after this procedure.

Medical therapy is less effective than invasive procedures. Smooth muscle relaxants such as nitrates (isosorbide dinitrate [Isordil]) and calcium channel blockers (e.g., nifedipine [Procardia]) taken sublingually 30 to 45 minutes before meals to improve dysphagia may be prescribed. However, side effects (e.g., headache), drug tolerance, and short duration of action limit their use.

The injection of botulinum toxin endoscopically into the LES gives short-term relief of symptoms and improves esophageal emptying. It works by promoting relaxation of the smooth muscle. This treatment is used for older patients for whom surgery and pneumatic dilation may not be appropriate due to other chronic illnesses. Symptomatic treatment consists of eating a semisoft diet, eating slowly and drinking fluid with meals, and sleeping with the head elevated.

Esophageal Varices

Esophageal varices are dilated, tortuous veins occurring in the lower portion of the esophagus as a result of portal hypertension. Esophageal varices are a common complication of liver cirrhosis and are discussed in Chapter 44.

DISORDERS OF THE STOMACH AND UPPER SMALL INTESTINE

GASTRITIS

Gastritis, an inflammation of the gastric mucosa, is one of the most common problems affecting the stomach. Gastritis may be acute or chronic and diffuse or localized.

TABLE 42-12 CAUSES OF GASTRITIS

Drugs
- Aspirin
- Corticosteroids
- Nonsteroidal antiinflammatory drugs (NSAIDs)

Diet
- Alcohol
- Spicy, irritating food

Microorganisms
- *Helicobacter pylori*
- *Salmonella* organisms
- *Staphylococcus* organisms

Environmental Factors
- Radiation
- Smoking

Pathophysiologic Conditions
- Burns
- Large hiatal hernia
- Physiologic stress
- Reflux of bile and pancreatic secretions
- Renal failure (uremia)
- Sepsis
- Shock

Other Factors
- Endoscopic procedures
- Nasogastric tube
- Psychologic stress

Etiology and Pathophysiology

Gastritis occurs as the result of a breakdown in the normal gastric mucosal barrier. This mucosal barrier normally protects the stomach tissue from the corrosive action of HCl acid and pepsin. When the barrier is broken, HCl acid and pepsin can diffuse back into the mucosa. This back diffusion results in tissue edema, disruption of capillary walls with loss of plasma into the gastric lumen, and possible hemorrhage.

Risk Factors. Risk factors and causes of gastritis are listed in Table 42-12. Some of the risk factors are discussed in this section.

Drug-Related Gastritis. Drugs contribute to the development of acute and chronic gastritis. NSAIDs, including aspirin, and corticosteroids inhibit the synthesis of prostaglandins that are protective to the gastric mucosa. Thus the mucosa is more susceptible to injury. NSAID-related gastritis is associated with many drugs, including piroxicam (Feldene), naproxen (Naprosyn), sulindac (Clinoril), indomethacin (Indocin), diclofenac (Voltaren), and ibuprofen (Motrin, Advil).[17]

Risk factors for NSAID-induced gastritis include being female; being over age 60; having a history of ulcer disease; taking anticoagulants, other NSAIDs (including low-dose aspirin), or other ulcerogenic drugs (including corticosteroids); and having a chronic debilitating disorder such as cardiovascular disease. Some drugs such as digitalis (digoxin) and alendronate (Fosamax) have direct irritating effects on the gastric mucosa.

Diet. Dietary indiscretions can also result in acute gastritis. After an alcoholic drinking binge, acute damage to the gastric mucosa can range from localized injury of superficial epithelial cells to destruction of the mucosa with mucosal congestion, edema, and hemorrhage. Prolonged damage induced by repeated alcohol abuse results in chronic gastritis. Eating large quantities of spicy, irritating foods and metabolic conditions such as renal failure can also cause acute gastritis.

Helicobacter pylori. An important cause of chronic gastritis is *Helicobacter pylori* infection. *H. pylori* infection is highest in underdeveloped countries and in people of low socioeconomic status. Infection likely occurs during childhood with transmission from family members to the child, possibly through a fecal-oral or oral-oral route.

In the United States, people born before 1940 are more likely to carry *H. pylori* than people in younger age-groups. *H. pylori* has also been linked to stomach cancer and non-Hodgkin's lymphoma. The role of *H. pylori* in ulcer development is discussed in greater detail in this chapter on p. 943.

Other Risk Factors. Although not as common, other risk factors of chronic gastritis have been identified. Bacterial, viral, and fungal infections, including *Mycobacterium* species, cytomegalovirus (CMV), and syphilis, are associated with chronic gastritis. Gastritis can occur from reflux of bile salts from the duodenum into the stomach as a result of anatomic changes following surgical procedures (e.g., gastroduodenostomy, gastrojejunostomy). Prolonged vomiting may also cause reflux of bile salts. Intense emotional responses and CNS lesions may also produce inflammation of the mucosal lining as a result of hypersecretion of HCl acid.

Autoimmune Gastritis. Autoimmune metaplastic atrophic gastritis (also called autoimmune atrophic gastritis) is an inherited condition in which there is an immune response directed against parietal cells. It most commonly affects women of northern European descent. Patients with autoimmune atrophic gastritis often have other autoimmune disorders. The loss of parietal cells leads to low chloride levels, inadequate production of intrinsic factor, cobalamin (vitamin B_{12}) malabsorption, and pernicious anemia. Atrophic gastritis is associated with an increased risk of stomach cancer.

Clinical Manifestations

In *acute gastritis* the symptoms include anorexia, nausea and vomiting, epigastric tenderness, and a feeling of fullness. Hemorrhage is commonly associated with alcohol abuse and at times is the only symptom. Acute gastritis is self-limiting, lasting from a few hours to a few days, with complete healing of the mucosa expected.

In *chronic gastritis* the manifestations are similar to those described for acute gastritis. Some patients are asymptomatic. However, when the parietal cells are lost as a result of atrophy, the source of intrinsic factor is also lost. The loss of *intrinsic factor,* a substance essential for the absorption of cobalamin in the terminal ileum, ultimately results in cobalamin deficiency. With time, the body's storage of cobalamin in the liver becomes depleted, and a state of deficiency exists. Because it is essential for the growth and maturation of red blood cells (RBCs), the lack of cobalamin results in pernicious anemia and neurologic complications. (Cobalamin deficiency anemia is discussed in Chapter 31.)

Diagnostic Studies

Diagnosis of acute gastritis is most often based on the patient's history of drug and alcohol use. Endoscopic examination with biopsy may be warranted to obtain a definitive diagnosis. Breath, urine, serum, stool, and gastric tissue biopsy tests are available for the determination of *H. pylori* infection. (These diagnostic tests are described in the section on peptic ulcer disease later in this chapter on p. 945.)

Radiologic studies are not helpful because the superficial mucosa is generally involved, and changes will not show clearly on x-ray examination. A complete blood count (CBC) may demonstrate anemia from blood loss or lack of intrinsic factor. Stools are tested for occult blood. Serum tests for antibodies to parietal cells and intrinsic factor may be performed. Tissue biopsy is necessary to rule out gastric carcinoma.

TABLE 42-13 DRUG THERAPY

Helicobacter pylori *Infection*

Treatment	Duration	Eradication Rate
Triple-Drug Therapy proton pump inhibitor (PPI)* amoxicillin clarithromycin (Biaxin)	7-14 days	70%-85%
Quadruple Therapy PPI* bismuth† tetracycline metronidazole (Flagyl)	10-14 days	85%

*See Table 42-10.
†Bismuth is part of a combination capsule (Pylera) containing bismuth, tetracycline, and metronidazole that is used in combination with a PPI (e.g., omeprazole [Prilosec]).

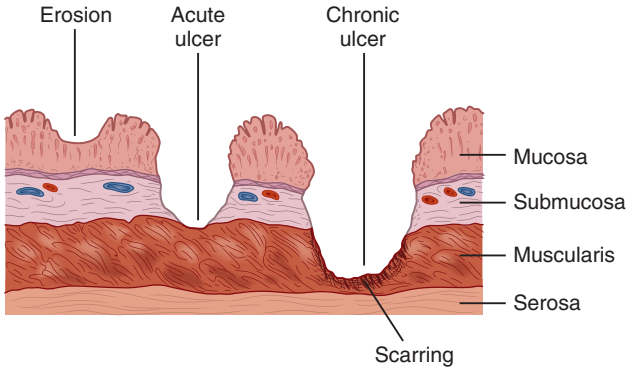

FIG. 42-9 Peptic ulcers, including an erosion, an acute ulcer, and a chronic ulcer. Both the acute ulcer and the chronic ulcer may penetrate the entire wall of the stomach.

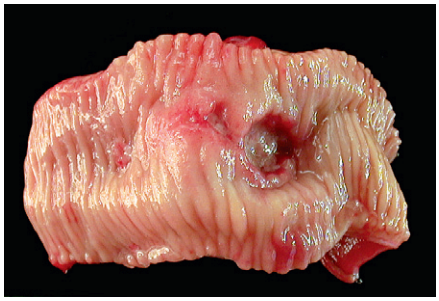

FIG. 42-10 Peptic ulcer of the duodenum.

NURSING AND COLLABORATIVE MANAGEMENT GASTRITIS

ACUTE GASTRITIS

Eliminating the cause and preventing or avoiding it in the future are generally all that is needed to treat acute gastritis. The plan of care is supportive and similar to that described for nausea and vomiting. If vomiting accompanies acute gastritis, rest, NPO status, and IV fluids may be prescribed. Dehydration can occur rapidly in acute gastritis with vomiting. Antiemetics are given for nausea and vomiting (see Table 42-1).

In severe cases of acute gastritis, an NG tube may be used (1) to monitor for bleeding, (2) to lavage the precipitating agent from the stomach, or (3) to keep the stomach empty and free of noxious stimuli. Clear liquids are resumed when symptoms have subsided, with gradual reintroduction of solids.

If hemorrhage is considered likely, frequently check vital signs and test the vomitus for blood. All of the management strategies discussed in the section on upper GI bleeding apply to the patient with severe gastritis (see p. 955).

Drug therapy focuses on reducing irritation of the gastric mucosa and providing symptomatic relief. H_2-receptor blockers (e.g., ranitidine, cimetidine) or PPIs (e.g., omeprazole, lansoprazole) reduce gastric HCl acid secretion (see Table 42-10). Teach the patient about the therapeutic effects of PPIs and H_2-receptor blockers.

CHRONIC GASTRITIS

The treatment of chronic gastritis focuses on evaluating and eliminating the specific cause (e.g., cessation of alcohol intake, abstinence from drugs, *H. pylori* eradication). Currently, antibiotic combinations are used to eradicate *H. pylori* (Table 42-13). For the patient with pernicious anemia, cobalamin (administered orally, nasally, or by injections) is needed (see Chapter 31). Discuss the need for lifelong cobalamin therapy with the patient.

The patient undergoing treatment for chronic gastritis may have to adapt to lifestyle changes and strictly adhere to a drug regimen. Some patients find a nonirritating diet consisting of six small feedings a day helpful. Smoking is contraindicated in all forms of gastritis. An interprofessional team approach in which the physician, nurse, dietitian, and pharmacist provide consistent information and support may increase the patient's success in making these alterations.

PEPTIC ULCER DISEASE

Peptic ulcer disease (PUD) is a condition characterized by erosion of the GI mucosa resulting from the digestive action of HCl acid and pepsin. Any portion of the GI tract that comes into contact with gastric secretions is susceptible to ulcer development, including the lower esophagus, stomach, duodenum, and margin of a gastrojejunal anastomosis after surgical procedures. Approximately 350,000 new cases of ulcers are diagnosed each year.

Types

Peptic ulcers can be classified as acute or chronic, depending on the degree and duration of mucosal involvement, and gastric or duodenal, according to the location. The *acute ulcer* (Fig. 42-9) is associated with superficial erosion and minimal inflammation. It is of short duration and resolves quickly when the cause is identified and removed. A chronic ulcer (Fig. 42-10) is one of long duration, eroding through the muscular wall with the formation of fibrous tissue. It is present continuously for many months or intermittently throughout the person's lifetime. Chronic ulcers are more common than acute erosions.

Gastric and duodenal ulcers, although defined as PUD, are different in their etiology and incidence (Table 42-14). Generally, the treatment of all types of ulcers is similar.

Etiology and Pathophysiology

Peptic ulcers develop only in an acid environment. However, an excess of HCl acid may not be necessary for ulcer development. Pepsinogen, the precursor of pepsin, is activated to pepsin in the presence of HCl acid and a pH of 2 to 3. When the stomach acid level is neutralized by food or antacids or acid secretion is

TABLE 42-14 COMPARISON OF GASTRIC AND DUODENAL ULCERS

Gastric Ulcers	Duodenal Ulcers
Lesion	
Superficial, smooth margins Round, oval, or cone shaped	Penetrating (associated with deformity of duodenal bulb from healing of recurrent ulcers)
Location of Lesion	
Predominantly antrum, also in body and fundus of stomach	First 1-2 cm of duodenum
Gastric Secretion	
Normal to decreased	Increased
Incidence	
Greater in women	Greater in men, but increasing in women (especially postmenopausal)
Peak age 50-60 yr	Peak age 35-45 yr
More common in people of lower socioeconomic status	Associated with psychologic stress
↑ With smoking, drug use (aspirin, NSAID), and alcohol use	↑ With smoking, drug use, and alcohol use
↑ With incompetent pyloric sphincter and bile reflux	Associated with other diseases (e.g., chronic obstructive pulmonary disease, pancreatic disease, hyperparathyroidism, Zollinger-Ellison syndrome, chronic renal failure)
Clinical Manifestations	
Burning or gaseous pressure in high left epigastrium and back and upper abdomen	Burning, cramping, pressure-like pain across midepigastrium and upper abdomen. Back pain with posterior ulcers
Pain 1-2 hr after meals. If penetrating ulcer, aggravation of discomfort with food	Pain 2-4 hr after meals and midmorning, midafternoon, middle of night. Periodic and episodic. Pain relief with antacids and food
Occasional nausea and vomiting, weight loss	Occasional nausea and vomiting
Recurrence Rate	
High	High
Complications	
Hemorrhage, perforation, gastric outlet obstruction, intractability	Hemorrhage, perforation, obstruction

blocked by drugs, the pH is increased to 3.5 or more. At a pH of 3.5 or more, pepsin has little or no proteolytic activity.

The pathophysiology of ulcer development is outlined in Fig. 42-11. The back diffusion of HCl acid into the gastric mucosa results in cellular destruction and inflammation. Histamine is released from the damaged mucosa, resulting in vasodilation and increased capillary permeability and further secretion of acid and pepsin. Fig. 42-12 depicts the interrelationship between the mucosal blood flow and disruption of the gastric mucosal barrier. As described in the section on gastritis, a variety of agents are known to damage the mucosal barrier.

Helicobacter pylori. In addition to chronic gastritis, *H. pylori* is associated with peptic ulcer development. Approximately two thirds of the world's population is infected with *H. pylori*.[18]

PATHOPHYSIOLOGY MAP

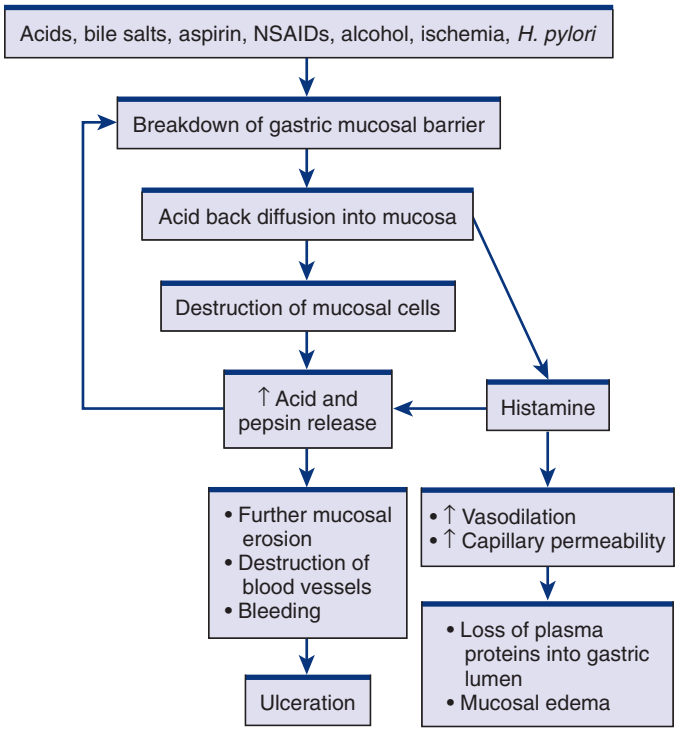

FIG. 42-11 Disruption of gastric mucosa and pathophysiologic consequences of back diffusion of acids.

In the stomach the bacteria can survive a long time by colonizing the gastric epithelial cells within the mucosal layer. The bacteria also produce urease, which metabolizes urea-producing ammonium chloride and other damaging chemicals. Urease also activates the immune response with both antibody production and the release of inflammatory cytokines.

The response to *H. pylori* is variable. Not all individuals infected with *H. pylori* go on to develop ulcers. In one scenario, *H. pylori* leads to intestinal metaplasia in the stomach resulting in chronic atrophic gastritis and in some cases stomach cancer. In another scenario, *H. pylori* alters gastric secretion and produces tissue damage, leading to PUD. The response to *H. pylori* is influenced by a variety of factors, including genetics, environment, and diet.

Medication-Induced Injury. Ulcerogenic drugs, such as aspirin and NSAIDs, inhibit synthesis of prostaglandins, increase gastric acid secretion, and reduce the integrity of the mucosal barrier. The use of NSAIDs is responsible for the majority of non–*H. pylori* peptic ulcers. NSAIDs in the presence of *H. pylori* increase the risk of PUD.[17] Patients on corticosteroids, anticoagulants, and selective serotonin reuptake inhibitors (e.g., fluoxetine [Prozac]) are also at increased risk of ulcer development.[19] Corticosteroids affect mucosal cell renewal and decrease its protective effects.

Lifestyle Factors. High alcohol intake is associated with acute mucosal lesions. In addition, alcohol stimulates acid secretion. Coffee (caffeinated and decaffeinated) is a strong stimulant of gastric acid secretion. Psychologic distress, including stress and depression, can negatively influence the healing of ulcers once they have developed. Smoking also delays ulcer healing.

PATHOPHYSIOLOGY MAP

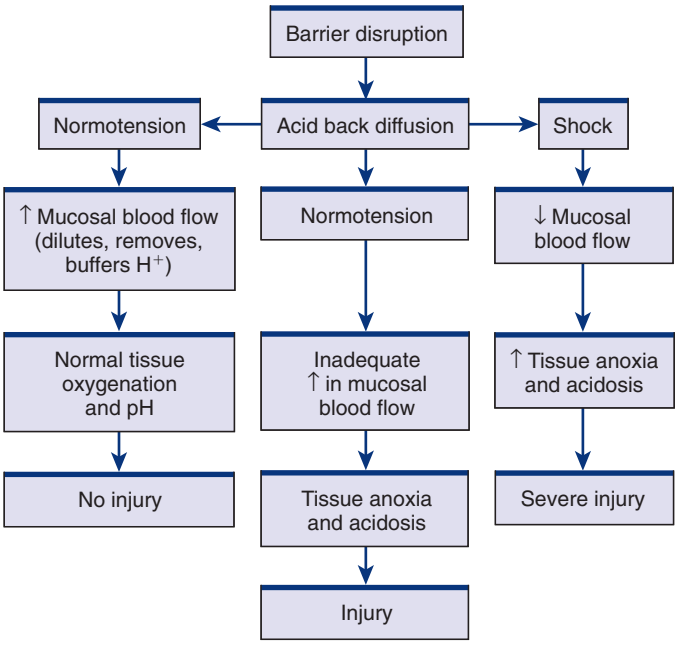

FIG. 42-12 Relationship between mucosal blood flow and disruption of the gastric mucosal barrier.

Gastric Ulcers. Although gastric ulcers can occur in any portion of the stomach, they are most commonly found in the antrum. Gastric ulcers are less common than duodenal ulcers. Gastric ulcers are more prevalent in women and in older adults. Because the peak incidence of gastric ulcers is in people over 50 years of age, the mortality rate from gastric ulcers is greater than that from duodenal ulcers. Gastric ulcers are more likely than duodenal ulcers to result in obstruction. *H. pylori,* medications, smoking, and bile reflux are risk factors for gastric ulcers.

Duodenal Ulcers. Duodenal ulcers account for about 80% of all peptic ulcers. Duodenal ulcers may occur at any age, but the incidence is especially high between 35 and 45 years of age. Duodenal ulcers can develop in anyone, regardless of occupation or socioeconomic group.

Although many factors are associated with the development of duodenal ulcers, *H. pylori* is most common. *H. pylori* infection is found in approximately 90% to 95% of patients with duodenal ulcers.

The development of duodenal ulcers is often associated with a high HCl acid secretion. Alcohol ingestion and smoking are associated with duodenal ulcer formation because both are known stimulants of acid secretion. Several patient groups are at high risk of duodenal ulcer development, including those with chronic obstructive pulmonary disease, cirrhosis of the liver, chronic pancreatitis, hyperparathyroidism, chronic kidney disease, and *Zollinger-Ellison syndrome* (a rare condition characterized by severe peptic ulceration and HCl acid hypersecretion).

Stress-Related Mucosal Disease (SRMD). SRMD is described later in this chapter in the section on acute upper GI bleeding on p. 954.

Clinical Manifestations

The discomfort generally associated with gastric ulcers is located high in the epigastrium and occurs about 1 to 2 hours after meals. The pain is described as "burning" or "gaseous." If the ulcer has eroded through the gastric mucosa, food tends to aggravate rather than alleviate the pain. For some patients, the earliest symptoms are due to a serious complication such as perforation.

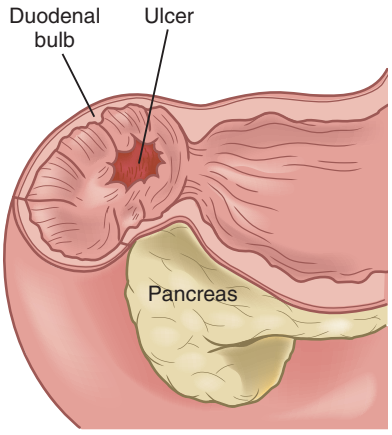

FIG. 42-13 Duodenal ulcer of the posterior wall penetrating into the head of the pancreas, resulting in walled-off perforation.

The symptoms of duodenal ulcers occur when gastric acid comes in contact with the ulcers. With meal ingestion, food is present to help buffer the acid. Symptoms of duodenal ulcers occur generally 2 to 5 hours after a meal. The pain is described as "burning" or "cramplike." It is most often located in the midepigastric region beneath the xiphoid process. Duodenal ulcers can also produce back pain.

Antacids alone or in combination with an H_2-receptor blocker, as well as food, neutralize the acid to provide relief. A characteristic of duodenal ulcer is its tendency to occur continuously for a few weeks or months and then disappear for a time, only to recur some months later.

Not all patients with gastric or duodenal ulcers experience pain or discomfort. *Silent* peptic ulcers are more likely to occur in older adults and those taking NSAIDs. The presence or absence of symptoms is not directly related to the size of the ulcer or the degree of healing.

Complications

The three major complications of chronic PUD are hemorrhage, perforation, and gastric outlet obstruction. All are considered emergency situations and may require surgical intervention.

Hemorrhage. Hemorrhage is the most common complication of PUD. Duodenal ulcers account for a greater percentage of upper GI bleeding episodes than gastric ulcers.

Perforation. Perforation is considered the most lethal complication of PUD. Perforation is commonly seen in large penetrating duodenal ulcers (Fig. 42-13). Even though duodenal ulcers are more prevalent and perforate more often, mortality rates associated with perforation of gastric ulcers are higher. The patient with gastric ulcers is older and often has concurrent medical problems, which accounts for the higher mortality rate.

With perforation, the ulcer penetrates the serosal surface with spillage of either gastric or duodenal contents into the peritoneal cavity. Small perforations seal themselves, resulting in a cessation of symptoms. Larger perforations require immediate surgical closure. Spontaneous sealing occurs as a result of fibrin production in response to the perforation. This can lead to fibrinous fusion of the duodenum or gastric curvature to adjacent tissue (mainly the liver) and strictures that can obstruct the flow of intestinal contents and the passage of stool.

The clinical manifestations of perforation are sudden and dramatic in onset. During the initial phase (0 to 2 hours after perforation) the patient experiences sudden, severe upper abdominal pain that quickly spreads throughout the abdomen. The pain radiates to the back and is not relieved by food or antacids. The abdomen appears rigid and boardlike as the abdominal muscles attempt to protect from further injury. The patient's respirations become shallow and rapid. The heart rate is elevated (tachycardia), and the pulse is weak. Bowel sounds are usually absent. Nausea and vomiting may occur. Many patients report a history of ulcer disease or recent symptoms of indigestion.

The contents entering the peritoneal cavity from the stomach or duodenum may contain air, saliva, food particles, HCl acid, pepsin, bacteria, bile, and pancreatic fluid and enzymes. If the condition is untreated, bacterial peritonitis may occur within 6 to 12 hours. The intensity of the peritonitis is proportional to the amount and duration of the spillage through the perforation. It is difficult to determine from the symptoms alone whether a gastric or duodenal ulcer has perforated because the clinical characteristics of intestinal perforation are the same (see Chapter 43).

Gastric Outlet Obstruction. Both acute and chronic PUD can result in gastric outlet obstruction. Obstruction in the distal stomach and duodenum is the result of edema, inflammation, or pylorospasm and fibrous scar tissue formation. With obstruction the patient reports discomfort or pain that is worse toward the end of the day as the stomach fills and dilates. Relief may be obtained by belching or by self-induced vomiting. Vomiting is common and often projectile. The vomitus contains food particles that were ingested hours or days before the vomiting episode. Constipation occurs because of dehydration and decreased diet intake secondary to anorexia. Over time dilation of the stomach and visible swelling in the upper abdomen may occur.

Diagnostic Studies

The diagnostic tests used to determine the presence and location of an ulcer are similar to those used for acute upper GI bleeding. Endoscopy is the most accurate diagnostic procedure. Endoscopy allows for direct viewing of the gastric and duodenal mucosa (Fig. 42-14). It can be used to determine the degree of ulcer healing after treatment and to confirm the absence of malignancy. During endoscopy, tissue specimens are obtained for identification of *H. pylori* and to rule out stomach cancer.

Several diagnostic tests are available to confirm *H. pylori* infection. These are classified as noninvasive and invasive. Biopsy of the antral mucosa and testing for urease (rapid urease testing) is considered the gold standard for diagnosis of *H. pylori* infection. Noninvasive tests include stool testing or breath testing. Serum or whole blood antibody tests, particularly immunoglobulin G (IgG), do not distinguish between past and current infection. The urea breath test can identify active infection. Urea is a by-product of the metabolism of *H. pylori* bacteria. Although not as accurate as the urea breath test, stool antigen tests can also be performed.

A barium contrast study may be used in the diagnosis of gastric outlet obstruction or for ulcer detection in those patients who cannot undergo endoscopy. The presence of a possible gastrinoma (Zollinger-Ellison syndrome) can be diagnosed by measuring fasting serum gastrin levels. With a gastrinoma, the gastrin levels are elevated. A secretin stimulation test can differentiate patients with gastrinomas from those with other causes of hypergastrinemia.

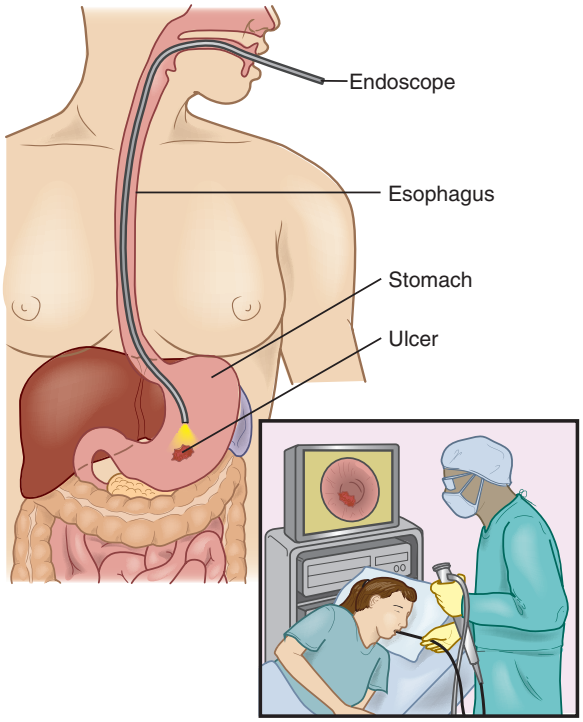

FIG. 42-14 Esophagogastroduodenoscopy (EGD) directly visualizes the mucosal lining of the stomach with a flexible endoscope. Ulcers or tumors can be directly visualized and biopsies taken.

Laboratory tests, including a CBC, liver enzyme studies, serum amylase determination, and stool examination, should be performed. A CBC may indicate anemia secondary to ulcer bleeding. Liver enzyme studies help detect any liver problems (e.g., cirrhosis) that may complicate ulcer treatment. Stools are routinely tested for blood. A serum amylase determination is done to determine pancreatic function when posterior duodenal ulcer penetration of the pancreas is suspected.

Collaborative Care

Conservative Therapy

When the patient's clinical manifestations and health history suggest the diagnosis of PUD and diagnostic studies confirm it, a treatment regimen is instituted (Table 42-15). The regimen consists of adequate rest, drug therapy, elimination of smoking, dietary modifications (if needed), and long-term follow-up care. The aim of treatment is to decrease gastric acidity and enhance mucosal defense mechanisms.

Patients are generally treated in ambulatory care clinics. Pain disappears after 3 to 6 days, but ulcer healing is much slower. Complete healing may take 3 to 9 weeks, depending on ulcer size, treatment regimen, and patient adherence. Endoscopic examination is the most accurate method to monitor for ulcer healing. The usual follow-up endoscopic evaluation is performed 3 to 6 months after diagnosis and treatment.

Aspirin and nonselective NSAIDs are discontinued for 4 to 6 weeks. When aspirin must be continued, co-administration with a PPI, H_2-receptor blocker, or misoprostol (Cytotec) may be prescribed. Patients with *H. pylori* infection are treated with antibiotics and a PPI. Patients receiving low-dose aspirin for cardiovascular and stroke risk who have a history of ulcer disease or complications may need to receive long-term treatment with a PPI.[20] Enteric-coated aspirin decreases localized

TABLE 42-15 COLLABORATIVE CARE

Peptic Ulcer Disease

Diagnostic
- History and physical examination
- Upper GI endoscopy with biopsy
- *Helicobacter pylori* testing of breath, urine, blood, tissue
- Complete blood cell count
- Liver enzymes
- Serum electrolytes

Collaborative Therapy

Conservative Therapy
- Adequate rest
- Cessation of smoking
- Drug therapy (see Tables 42-9 and 42-13)
  - Proton pump inhibitors
  - H_2-receptor blockers
  - Antibiotics for *H. pylori*
  - Cytoprotective drugs
  - Antacids
  - Anticholinergics (used rarely)
- Stress management (see Chapter 7)

Acute Exacerbation Without Complications
- NPO
- NG suction
- Adequate rest
- IV fluid replacement
- Drug therapy
  - Proton pump inhibitors
  - H_2-receptor blockers
  - Antacids
  - Anticholinergics
  - Sedatives

Acute Exacerbation With Complications (Hemorrhage, Perforation, Obstruction)
- NPO
- NG suction
- IV proton pump inhibitor
- Bed rest
- IV fluid replacement (lactated Ringer's solution)
- Blood transfusions
- Stomach lavage (possible)

Surgical Therapy
- *Perforation:* Simple closure with omentum graft
- *Gastric outlet obstruction:* Pyloroplasty and vagotomy
- *Ulcer removal or reduction*
  - Billroth I and II
  - Vagotomy and pyloroplasty

irritation but has not been proved to reduce the overall risk for GI bleeding.

Smoking has an irritating effect on the mucosa and delays mucosal healing. Smoking should be eliminated completely or severely reduced. (Strategies to enhance patient smoking cessation are discussed in Chapter 11.) Adequate rest, both physical and emotional, is important for ulcer healing and may require some modifications in the patient's daily routine. Avoidance or restriction of alcohol intake will also enhance healing.

Drug Therapy. Drugs are a vital part of therapy (see Table 42-10). Strict adherence to the prescribed regimen of drugs is important. Teach the patient about each drug prescribed, why it is ordered, and the expected benefits.

Because ulcers frequently recur, interruption or discontinuation of therapy can have harmful results. Encourage the patient to adhere to therapy and continue with follow-up care as prescribed. H_2-receptor blockers and PPIs may be stopped after the ulcer has healed or may be prescribed as low-dose maintenance therapy. Teach the patient and the family what to do if pain and discomfort recur or blood is noted in the vomitus or stools.

Histamine (H_2)-Receptor Blockers. H_2-receptor blockers promote ulcer healing. Famotidine, ranitidine, and cimetidine can be given orally or IV, but nizatidine is only available orally. Depending on the specific drug, therapeutic effects last up to 12 hours. The onset of action of H_2-receptor blockers is 1 hour, which is longer than antacids.

Proton Pump Inhibitors. PPIs are more effective than H_2-receptor blockers in reducing gastric acid secretion and promoting ulcer healing. PPIs are also used in combination with antibiotics to treat ulcers caused by *H. pylori*. Omeprazole is available in an OTC formulation at a lower dose and in an immediate-release form.

Antibiotic Therapy. The treatment of *H. pylori* is the most important element of treating PUD in patients positive for *H. pylori.* Antibiotic therapy for *H. pylori* is shown in Table 42-13. Antibiotics are prescribed concurrently with a PPI for 7 to 14 days. Because of the development of antibiotic-resistant organisms, a growing percentage of patients do not have the *H. pylori* eradicated with a single round of therapy.

Antacids. Antacids are used as adjunct therapy for PUD. They increase gastric pH by neutralizing the HCl acid. As a result, the acid content of chyme reaching the duodenum is reduced. In addition, some antacids, such as aluminum hydroxide, can bind to bile salts, thus decreasing the damaging effects of bile on the gastric mucosa. Patients who are at risk for SRMD may be treated prophylactically with antacids along with an antisecretory agent.

The common commercial nonsystemic (poorly absorbed) antacids consist of magnesium hydroxide or aluminum hydroxide as single preparations or in various combinations (see Table 42-10). The neutralizing effects of antacids taken on an empty stomach last only 20 to 30 minutes because they are quickly evacuated. When antacids are taken after meals, the effects may last as long as 3 to 4 hours. Therapy recommending frequent dosing (e.g., hourly) often results in poor adherence.

After the acute phase of bleeding, antacids are generally administered hourly, either orally or through the NG tube. If the tube is in place, the stomach contents should be aspirated and tested periodically for pH level. If pH is less than 5, intermittent suction may be used, or the frequency or dosage of the antacid or antisecretory agent may be increased.

The type and dosage of antacid prescribed depend on side effects and potential drug interactions. Antacids high in sodium (e.g., sodium citrate [Bicitra]) need to be used with caution in older adults and patients with liver cirrhosis, hypertension, heart failure, and renal disease. Magnesium preparations should not be prescribed for patients with renal failure because of the risk of magnesium toxicity. An antacid combination of aluminum and magnesium seems to decrease the side effects of both.

Antacids can interact unfavorably with some drugs. They can enhance the absorption of drugs such as dicumarol and amphetamines. Digitalis preparations can be potentiated when taken in combination with calcium or magnesium antacids. In some instances, antacids decrease the absorption rates of prescribed drugs, such as tetracycline. Before antacid therapy begins, inform the health care provider of any drugs that a patient is taking.

Cytoprotective Drug Therapy. Sucralfate is used for the short-term treatment of ulcers. It provides cytoprotection for the esophagus, stomach, and duodenum. Sucralfate does not have acid-neutralizing capabilities. Its action is most effective at a low pH, and it should be given at least 30 minutes before or after an antacid. Adverse side effects are minimal. However, it does bind with cimetidine, digoxin, warfarin (Coumadin), phenytoin (Dilantin), and tetracycline, causing reduced bioavailability of these drugs.

Misoprostol is a synthetic prostaglandin analog prescribed for the prevention of gastric ulcers caused by NSAIDs and aspirin. It has protective and some antisecretory effects on gastric mucosa. Misoprostol does not interfere with the therapeutic effects of aspirin and NSAIDs. People who require chronic NSAID therapy, such as those with osteoarthritis, may benefit from the use of misoprostol.

Other Drugs. Tricyclic antidepressants (e.g., imipramine [Tofranil], doxepin [Sinequan]) may be prescribed for patients with PUD. Antidepressants may contribute to overall pain relief through their effects on afferent pain fiber transmission. In addition, tricyclic antidepressants have (to varying degrees) some anticholinergic properties, which result in reduced acid secretion. Selective serotonin reuptake inhibitors are associated with a modest risk for upper GI bleeding.[19]

Anticholinergic drugs are used only occasionally for PUD treatment. Anticholinergics are associated with a number of side effects, such as dry mouth, warm skin, flushing, thirst, tachycardia, dilated pupils, blurred vision, and urine retention.

Nutritional Therapy. There is no specific recommended dietary modification for PUD. Patients are taught to eat and drink foods and fluids that do not cause any distressing symptoms. Caffeine-containing beverages and foods can increase symptom distress in some patients. Teach the patient to eliminate alcohol because it can delay healing. Foods that commonly cause gastric irritation include hot, spicy foods; pepper; carbonated beverages; and broth (meat extract).

Therapy Related to Complications of Peptic Ulcer Disease

Acute Exacerbation. An acute exacerbation is frequently accompanied by bleeding, increased pain and discomfort, and nausea and vomiting. Management is similar to that described for upper GI bleeding later in this chapter (see pp. 955-957).

Perforation. The immediate focus of management of a patient with a perforation is to stop the spillage of gastric or duodenal contents into the peritoneal cavity and restore blood volume. An NG tube is inserted into the stomach to provide continuous aspiration and gastric decompression to stop spillage through the perforation. For duodenal aspiration, the tube is placed as near to the perforation site as possible to facilitate decompression.

Circulating blood volume is replaced with lactated Ringer's and albumin solutions. These solutions substitute for the fluids lost from the vascular and interstitial space as the peritonitis develops. Blood replacement in the form of packed RBCs may be necessary. A central venous pressure line and an indwelling urinary catheter may be inserted and monitored hourly. The patient with a history of cardiac disease requires electrocardiographic (ECG) monitoring or placement of a pulmonary artery catheter for accurate assessment of left ventricular function. Broad-spectrum antibiotic therapy is started immediately to treat bacterial peritonitis. Administration of pain medications provides comfort.

Either open or laparoscopic procedures are used for perforation repair depending on the location of the ulcer and the surgeon's preference. The procedure involving the least risk to the patient is simple oversewing of the perforation and reinforcement of the area with a graft of omentum. The excess gastric contents are suctioned from the peritoneal cavity during the surgical procedure.

Gastric Outlet Obstruction. The aim of therapy for obstruction is to decompress the stomach, correct any existing fluid and electrolyte imbalances, and improve the patient's general state of health. An NG tube is used as described previously. With continuous decompression for several days, the ulcer can begin healing, and the inflammation and edema will subside.

After several days of suction, clamp the NG tube and measure gastric residual volume periodically. The frequency and amount of time the tube remains clamped are related to the amount of aspirate obtained and the patient's comfort level. A method commonly followed is to clamp the tube overnight for approximately 8 to 12 hours and then measure the gastric residue in the morning. When the aspirate falls below 200 mL, this is within a normal range and the patient can begin oral intake of clear liquids. Oral fluids begin at 30 mL/hr and then gradually increase in amount. Assess the patient for signs and symptoms of distress or vomiting. As the amount of gastric residue decreases, solid foods are added and the tube removed.

IV fluids and electrolytes are administered according to the degree of dehydration, vomiting, and electrolyte imbalance indicated by laboratory studies. Pain relief results from the decompression. A PPI or H_2-receptor blocker is used if the obstruction is due to an active ulcer as determined by endoscopy. Pyloric obstruction may be treated endoscopically by balloon dilations. Surgical intervention may be necessary to remove scar tissue.

NURSING MANAGEMENT PEPTIC ULCER DISEASE

NURSING ASSESSMENT

Subjective and objective data to obtain from a patient with PUD are presented in Table 42-16.

NURSING DIAGNOSES

Nursing diagnoses related to PUD may include, but are not limited to, the following:

- Acute pain *related to* increased gastric secretions
- Ineffective self–health management *related to* lack of knowledge of long-term management of PUD
- Nausea *related to* acute exacerbation of disease process

Additional information on nursing diagnoses for the patient with PUD is presented in eNursing Care Plan 42-2 on the website for this chapter.

PLANNING

The overall goals are that the patient with PUD will (1) adhere to the prescribed therapeutic regimen, (2) experience a reduction in or absence of discomfort, (3) exhibit no signs of GI complications, (4) have complete healing of the peptic ulcer, and (5) make appropriate lifestyle changes to prevent recurrence.

NURSING IMPLEMENTATION

HEALTH PROMOTION. You have an important role in identifying patients at risk for PUD. Early detection and effective treat-

TABLE 42-16 NURSING ASSESSMENT

Peptic Ulcer Disease

Subjective Data

Important Health Information

Past health history: Chronic kidney disease, pancreatic disease, chronic obstructive pulmonary disease, serious illness or trauma, hyperparathyroidism, cirrhosis of the liver, Zollinger-Ellison syndrome

Medications: Aspirin, corticosteroids, nonsteroidal antiinflammatory drugs

Surgery or other treatments: Complicated or prolonged surgery

Functional Health Patterns

Health perception–health management: Chronic alcohol abuse, smoking, caffeine use; family history of peptic ulcer disease

Nutritional-metabolic: Weight loss, anorexia, nausea and vomiting, hematemesis, dyspepsia, heartburn, belching

Elimination: Black, tarry stools

Cognitive-perceptual

Duodenal ulcers: Burning, midepigastric or back pain occurring 2-4 hr after meals and relieved by food; nocturnal pain common

Gastric ulcers: High epigastric pain occurring 1-2 hr after meals; pain may be precipitated or aggravated by food

Coping-stress tolerance: Acute or chronic stress

Objective Data

General

Anxiety, irritability

Gastrointestinal

Epigastric tenderness

Possible Diagnostic Findings

Anemia; guaiac-positive stools; positive blood, urine, breath, or stool tests for *Helicobacter pylori;* abnormal upper gastrointestinal endoscopic and barium studies

ment of ulcers are important aspects of reducing morbidity risks associated with PUD. Patients who are taking ulcerogenic drugs (e.g., aspirin, NSAIDs) are at risk for PUD. Encourage patients to take these drugs with food. Teach patients to report symptoms related to gastric irritation, including epigastric pain, to their health care provider.

ACUTE INTERVENTION. During the acute exacerbation of an ulcer, the patient often complains of increased pain and nausea and vomiting, and some may have evidence of bleeding. Initially many patients attempt to cope with the symptoms at home before seeking medical assistance.

During this acute phase the patient may be NPO for a few days, have an NG tube inserted and connected to intermittent suction, and have IV fluid replacement. Explain to the patient and the caregiver the reasons for these therapies so they understand that the advantages far outweigh any temporary discomfort. Regular mouth care alleviates the dry mouth. Cleansing and lubrication of the nares facilitate breathing and decrease soreness. Analysis of gastric contents may include pH testing and analysis for blood, bile, or other substances. When the stomach is empty of gastric secretions, the ulcer pain diminishes and ulcer healing begins.

The volume of fluid lost, the patient's signs and symptoms, and laboratory test results (hemoglobin, hematocrit, and electrolytes) determine the type and amount of IV fluids administered. Be aware that other health problem (e.g., heart failure) may be adversely affected by the type or amount of fluid used. Take vital signs initially and at least hourly to detect and treat shock.

Physical and emotional rest is conducive to ulcer healing. The patient's immediate environment should be quiet and restful. The use of a mild sedative or tranquilizer has beneficial effects when the patient is anxious and apprehensive. Use good judgment before sedating a person who is becoming increasingly restless because the drug could mask the signs of shock secondary to upper GI bleeding.

If the patient's condition improves without worsening of symptoms (e.g., increased pain, vomiting, hemorrhage), the regimen outlined for conservative therapy is followed. However, complications such as hemorrhage, perforation, and obstruction can occur.

Hemorrhage. Changes in the vital signs and an increase in the amount and redness of the aspirate often signal massive upper GI bleeding. With bleeding, the patient's pain often decreases because the blood helps neutralize the acidic gastric contents. It is important to maintain the patency of the NG tube so that blood clots do not obstruct the tube. If the tube becomes blocked, the patient can develop abdominal distention. Use interventions similar to those described for upper GI bleeding on pp. 955-957.

Perforation. With perforation, the patient complains of sudden, severe abdominal pain. Perforation is manifested by a rigid, boardlike abdomen; severe generalized abdominal and shoulder pain; drawing up of the knees; and shallow, grunting respirations. The bowel sounds that may have been previously normal or hyperactive may diminish and become absent. When the patient with an ulcer demonstrates these changes, suspect perforation and notify the health care provider immediately.

Take vital signs promptly and record them every 15 to 30 minutes. Temporarily stop all oral or NG drugs and feedings until you can notify the health care provider and a definitive diagnosis is made. If perforation does exist, anything taken orally can add to the spillage into the peritoneal cavity and increase discomfort. If you are administering IV fluids at the time of the perforation, maintain the rate or increase it to replace the depleted plasma volume.

When perforation is confirmed, antibiotic therapy begins. When the perforation fails to seal spontaneously, surgical or laparoscopic closure is necessary and is performed as soon as possible. There may not be adequate time to thoroughly prepare the patient and family for the surgical intervention.

Gastric Outlet Obstruction. Gastric outlet obstruction can happen at any time. It is most likely to occur in the patient whose ulcer is located close to the pylorus. The onset of symptoms is usually gradual. Constant NG aspiration of stomach contents can help relieve symptoms. This allows edema and inflammation to subside and permits normal flow of gastric contents through the pylorus.

Regular irrigation of the tube with a normal saline solution per institutional policy may facilitate proper functioning. It may also be helpful to reposition the patient from side to side so that the tube tip is not constantly lying against the mucosal surface.

When the patient has resumed oral feedings and you notice symptoms of obstruction, promptly inform the health care provider. Generally, all that is necessary to treat the problem is to resume gastric aspiration so that the edema and inflammation resulting from the acute episode resolve. IV fluids with electrolyte replacement keep the patient hydrated during this period. To check for ongoing obstruction, clamp the NG tube intermittently and measure the gastric aspirate. It is important to maintain accurate intake and output records, especially of the gastric

TABLE 42-17 PATIENT & CAREGIVER TEACHING GUIDE

Peptic Ulcer Disease (PUD)

Include the following instructions when teaching the patient and caregiver about management of PUD.

1. Follow dietary modifications, including avoidance of foods that may cause epigastric distress. This may include black pepper, spicy foods, and acidic foods.
2. Avoid cigarettes. In addition to promoting ulcer development, smoking delays ulcer healing.
3. Reduce or eliminate alcohol intake.
4. Avoid OTC drugs unless approved by the health care provider. Many preparations contain ingredients, such as aspirin, that should not be taken unless approved by the health care provider. Check with the health care provider regarding the use of nonsteroidal antiinflammatory drugs.
5. Do not interchange brands of antacids, H_2-receptor blockers, and proton pump inhibitors that can be purchased OTC without checking with the health care provider. This can lead to harmful side effects.
6. Take all medications as prescribed. This includes both antisecretory and antibiotic drugs. Failure to take medications as prescribed can result in relapse.
7. It is important to report any of the following:
   - Increased nausea or vomiting
   - Increased epigastric pain
   - Bloody emesis or tarry stools
8. Stress can be related to signs and symptoms of PUD. Learn and use stress management strategies (see Chapter 7).
9. Share concerns about lifestyle changes and living with a chronic illness.

aspirate. When conservative treatment is not successful, surgery is performed after the acute phase has passed.

AMBULATORY AND HOME CARE. Patients with PUD have specific needs to prevent recurrence or complications. General instructions should cover aspects of the disease process itself, drugs, possible changes in lifestyle (alcohol intake, smoking), and regular follow-up care. Table 42-17 provides a patient and caregiver teaching guide for PUD.

Knowing the etiology and pathophysiology of PUD may motivate the patient to become involved in care and improve adherence to therapy. Work collaboratively with the dietitian to elicit a dietary history and plan ways to incorporate dietary modifications (if needed) into the patient's home and work setting.

The patient may not be honest about habitual use of alcohol or cigarettes. Provide information about the negative effects of alcohol and cigarettes on PUD and ulcer healing. Teach the patient about prescribed drugs, including their actions, side effects, and dangers if omitted for any reason. Make sure the patient knows why OTC drugs (e.g., aspirin, NSAIDs) should not be taken unless approved by the health care provider.[20] Because you can buy some H_2-receptor blockers and PPIs without a prescription, inform the patient that substituting prescription with OTC preparations without checking with the health care provider can lead to harmful side effects.

Try to obtain information about the patient's psychosocial status. Knowledge of lifestyle, occupation, and coping behaviors can be helpful in planning care. The patient may be reluctant to talk about personal subjects, the stress experienced at home or on the job, the usual methods of coping, or dependence on drugs or alcohol.

PUD is often a chronic, recurring disorder. Emphasize the need for long-term follow-up care, and encourage the patient to seek immediate intervention if symptoms return. The patient may be frustrated, especially if the prescribed mode of therapy has been faithfully followed, yet has failed to prevent the recurrence.

Some patients do not adhere to the plan of care, and they experience repeated exacerbations. Patients quickly learn that they often experience no discomfort when they omit prescribed drugs, smoke, or drink alcohol. Consequently, they make no or little alteration in lifestyle. After an acute exacerbation, the patient is likely to be more amenable to following the plan of care and open to suggestions for changes in lifestyle.

Changes, such as smoking cessation and alcohol abstinence, are difficult for many people. The patient may do better in reducing use of these substances rather than totally eliminating them. However, the goal should always be total cessation. Inform the patient with chronic PUD about potential complications, the clinical manifestations indicating their presence, and what to do until the health care provider can be seen.

EVALUATION

Expected outcomes are that the patient with PUD will

- Have pain controlled without the use of analgesics
- Verbalize an understanding of the treatment regimen
- Commit to self-care and management of the disease
- Have no complications (hemorrhage, perforation)

Additional information on expected outcomes for the patient with PUD is presented in eNursing Care Plan 42-2 on the website for this chapter.

Collaborative Care

Surgical Therapy for Peptic Ulcer Disease

With the use of antisecretory and antibiotic agents, surgery for PUD is uncommon. Surgery is performed on patients with complications that are unresponsive to medical management or concerns about stomach cancer.

Surgical procedures include partial gastrectomy, vagotomy, and pyloroplasty. Partial gastrectomy with removal of the distal two thirds of the stomach and anastomosis of the gastric stump to the duodenum is called a *gastroduodenostomy* or *Billroth I* operation (see eFig. 42-1 on the website for this chapter). Partial gastrectomy with removal of the distal two thirds of the stomach and anastomosis of the gastric stump to the jejunum is called a *gastrojejunostomy* or *Billroth II* operation (see eFig. 42-1).

Vagotomy is the severing of the vagus nerve, either totally *(truncal)* or selectively *(highly selective vagotomy)*. These procedures are done to decrease gastric acid secretion. *Pyloroplasty* consists of surgical enlargement of the pyloric sphincter to facilitate the easy passage of contents from the stomach. It is commonly done after vagotomy or to enlarge an opening that has been constricted from scar tissue.

Postoperative Complications. As with all surgeries, acute postoperative bleeding at the surgical site can occur. Monitoring of patients is similar to that described under acute upper GI bleeding. The most common long-term postoperative complications from PUD surgery are (1) dumping syndrome, (2) postprandial hypoglycemia, and (3) bile reflux gastritis.

Dumping Syndrome. *Dumping syndrome* is the direct result of surgical removal of a large portion of the stomach and the pyloric sphincter. Approximately 20% of patients experience dumping syndrome after PUD surgery.

Normally, gastric chyme enters the small intestine in small amounts. However, after surgery the stomach no longer has control over the amount of gastric chyme entering the small

intestine. Consequently, a large bolus of hypertonic fluid enters the intestine and results in fluid being drawn into the bowel lumen. This creates a decrease in plasma volume along with distention of the bowel lumen and rapid intestinal transit.

The onset of symptoms occurs within 15 to 30 minutes after eating. The patient usually describes feelings of generalized weakness, sweating, palpitations, and dizziness. These symptoms are due to the sudden decrease in plasma volume. The patient complains of abdominal cramps, *borborygmi* (audible abdominal sounds produced by hyperactive intestinal peristalsis), and the urge to defecate. These manifestations usually last less than 1 hour after eating.

Postprandial Hypoglycemia. *Postprandial hypoglycemia* is considered a variant of dumping syndrome because it is the result of uncontrolled gastric emptying of a bolus of fluid high in carbohydrate into the small intestine. The bolus of concentrated carbohydrate results in hyperglycemia and the release of excessive amounts of insulin into the circulation. This results in reflex hypoglycemia. Symptoms are similar to those of any hypoglycemic reaction and include sweating, weakness, mental confusion, palpitations, tachycardia, and anxiety. Symptoms generally occur 2 hours after eating.

Bile Reflux Gastritis. Gastric surgery that involves the pylorus, with either reconstruction or removal, can result in reflux of bile into the stomach. Prolonged contact with bile causes damage to the gastric mucosa, chronic gastritis, and recurrence of PUD.

The symptoms associated with reflux alkaline gastritis are continuous epigastric distress that increases after meals. Vomiting relieves the distress, but only temporarily. The administration of cholestyramine (Questran), either before or with meals, has been used successfully to treat this problem. Cholestyramine binds with the bile salts that are the source of gastric irritation.

Nutritional Therapy. Start discharge planning and teaching as soon as the immediate postoperative period is successfully passed. The dietitian usually gives dietary instructions, and you need to reinforce them. Because the stomach's reservoir is diminished after gastric resection, patients must reduce their meal size accordingly. Advise the patient to reduce fluids drunk with meals. Dry foods with a low carbohydrate content and moderate protein and fat content are better tolerated initially. Dietary changes, along with a short rest period after each meal, reduce the likelihood of dumping syndrome. Reassure the patient that the unpleasant symptoms are usually of short duration. Following these dietary measures will decrease symptoms within a few months and is essential to long-term adherence.

The immediate ingestion of sugared fluids or candy relieves the hypoglycemic symptoms. To avoid hypoglycemic episodes, instruct the patient to limit the amount of sugar consumed with each meal and to eat small, frequent meals with moderate amounts of protein and fat (Table 42-18). Although only a small percentage of patients experience bile reflux gastritis, caution the patient to notify the health care provider of any continuous epigastric distress after meals.

TABLE 42-18 NUTRITIONAL THERAPY

Postgastrectomy Dumping Syndrome

Purposes

- To slow the rapid passage of food into the intestine
- To control symptoms of dumping syndrome (dizziness, sense of fullness, diarrhea, tachycardia), which sometimes occurs after a partial or total gastrectomy

Diet Principles

- Divide meals into six small feedings to avoid overloading the stomach and intestine at mealtimes.
- Do not take fluids with meals but at least 30-45 min before or after meals. This helps prevent distention or a feeling of fullness.
- Avoid concentrated sweets (e.g., honey, sugar, jelly, jam, candies, sweet pastries, sweetened fruit) because they sometimes cause dizziness, diarrhea, and a sense of fullness.
- Increase protein and fats to promote rebuilding of body tissues and to meet energy needs. Meat, cheese, and eggs are specific foods to increase in the diet.
- Amount of time these restrictions should be followed varies. The health care provider decides the proper amount of time to remain on this prescribed diet according to the patient's clinical condition and progress.

NURSING MANAGEMENT SURGICAL THERAPY FOR PEPTIC ULCER DISEASE

PREOPERATIVE CARE

Given the greater use of endoscopic procedures for the treatment of PUD, surgical procedures are used less frequently. Surgery can involve either laparoscopic or open surgery techniques. When surgery is planned, the surgeon provides the necessary information about the procedure and the expected outcome so that the patient can make an informed decision. Help the patient and caregiver by clarifying and interpreting their questions. Instruct them on what to expect after surgery, including comfort measures, pain relief, coughing and breathing exercises, use of an NG tube, and IV fluid administration (see Chapter 18).

POSTOPERATIVE CARE

Care of the patient after major abdominal surgery is similar to the postoperative care after abdominal laparotomy (see Chapter 43). An NG tube is used to decompress the remaining portion of the stomach to decrease pressure on the suture line and to allow for resolution of edema and inflammation resulting from surgical trauma.

Observe the gastric aspirate for color, amount, and odor during the immediate postoperative period. The aspirate is usually bright red at first, with a gradual darkening within the first 24 hours after surgery. Normally the color changes to yellow-green within 36 to 48 hours. If the tube becomes clogged during this period, the health care provider may order periodic gentle irrigations with normal saline solution. It is essential that the NG suction is working and that the tube remains patent so that accumulated gastric secretions do not put a strain on the anastomosis. This can lead to distention of the remaining portion of the stomach and result in (1) rupture of the sutures, (2) leakage of gastric contents into the peritoneal cavity, (3) hemorrhage, and (4) possible abscess formation. If the tube must be replaced or repositioned, call the health care provider to perform this task because of the danger of perforating the gastric mucosa or disrupting the suture line.

Observe the patient for signs of decreased peristalsis, including abdominal distention and lower abdominal discomfort, which may indicate intestinal obstruction. Monitor and record accurate intake and output every 4 hours.

Keep the patient comfortable and free of pain by administering prescribed drugs and frequently changing position. In an

open surgical approach, the incision is relatively high in the epigastrium and may interfere with deep breathing and coughing. Splinting the area with a pillow while gently and persistently encouraging the patient to deep breathe helps prevent pulmonary complications. Splinting also protects the abdominal suture line from rupturing during coughing. Observe the dressing for signs of bleeding or odor and drainage indicative of an infection. Encourage early ambulation.

While the NG tube is connected to suction, maintain IV therapy. Add potassium and vitamin supplements (as ordered) to the infusion until oral feedings are resumed. Before the NG tube is removed, the patient begins oral feedings of clear liquids to determine the tolerance level. The stomach may be aspirated within 1 or 2 hours to assess the amount remaining and its color and consistency. When fluids are well tolerated, the NG tube is removed and fluids are increased in frequency, with a slow progression to regular foods. The patient begins the regimen of six small meals a day.

Pernicious anemia is a long-term complication of total gastrectomy and may occur after partial gastrectomy. Pernicious anemia is due to the loss of intrinsic factor, which is produced by the parietal cells. The patient may require cobalamin replacement therapy (see Chapter 31). PUD is a chronic problem, and ulcers can recur, especially at the site of the anastomosis.

GERONTOLOGIC CONSIDERATIONS

PEPTIC ULCER DISEASE

The morbidity and mortality rates associated with PUD in the older patient are higher than those for younger adults because of concomitant health problems and a decreased ability to withstand hypovolemia. Monitor older adults who use NSAIDs for osteoarthritis for signs and symptoms of PUD. In older patients, pain may not be the first symptom associated with an ulcer. For some patients the first manifestation is frank gastric bleeding or a decrease in hematocrit.

The treatment and management of PUD in older adults are similar to those in younger adults. An emphasis is placed on prevention of both gastritis and PUD. This includes teaching the patient to take NSAIDs and other gastric-irritating drugs with food, milk, or antacids. Instruct the patient to avoid irritating substances, adhere to the PPI or H_2-receptor blocker therapy as prescribed, and report abdominal pain or discomfort to the health care provider.

STOMACH CANCER

Stomach (gastric) **cancer** is an adenocarcinoma of the stomach wall (Fig. 42-15). The rate of stomach (particularly distal) cancer has been steadily declining in the United States. However, cancer of the cardia and the gastroesophageal junction is increasing. Gastric cancer still accounts for more than 10,540 deaths and 21,320 new cancer cases annually.[5]

Asian Americans and Pacific Islanders, Hispanics, and African Americans have higher rates of stomach cancer than non-Hispanic whites. Stomach cancer is more prevalent in men of the lower socioeconomic class, primarily those living in urban areas. The incidence of stomach cancer increases with age, with the majority being diagnosed between 65 and 80. At the time of diagnosis, only 10% to 20% of patients have disease confined to the stomach, and more than 50% have advanced metastatic disease. The 5-year survival rate is 80% in patients with early stages (confined to the stomach) and less than 30% in those with advanced disease.[5]

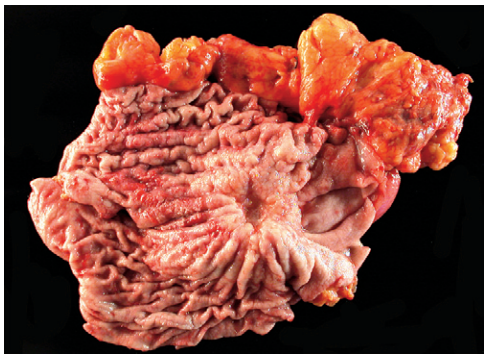

FIG. 42-15 Stomach carcinoma. Gross photograph showing an ill-defined, excavated central ulcer surrounded by irregular, heaped-up borders.

Etiology and Pathophysiology

Many factors have been implicated in the development of stomach cancer, yet no single causative agent has been identified.[21] Stomach cancer probably begins with a nonspecific mucosal injury as a result of infection *(H. pylori),* autoimmune-related inflammation, repeated exposure to irritants such as bile, antiinflammatory agents, and tobacco use.

Stomach cancer has been associated with diets containing smoked foods, salted fish and meat, and pickled vegetables. Whole grains and fresh fruits and vegetables are associated with reduced rates of stomach cancer. Infection with *H. pylori,* especially at an early age, is a risk factor for stomach cancer. It is possible that *H. pylori* and resulting cell changes can induce a sequence of transitions from dysplasia to cancer. Individuals with lymphoma of the stomach (mucosa-associated lymphoid tissue [MALT]) are at higher risk of stomach cancer.

Other predisposing factors include atrophic gastritis, pernicious anemia, adenomatous polyps, hyperplastic polyps, and achlorhydria. Smoking and obesity both increase the risk of stomach cancer. Although first-degree relatives of patients with stomach cancer are at increased risk, only 8% to 10% of stomach cancers have an inherited familial component.[21]

Stomach cancer spreads by direct extension and typically infiltrates rapidly to the surrounding tissue and liver. Seeding of tumor cells into the peritoneal cavity occurs late in the course of the disease.

Clinical Manifestations

Stomach cancers often spread to adjacent organs before any distressing symptoms occur. The clinical manifestations can include unexplained weight loss, early satiety, indigestion, abdominal discomfort or pain, and signs and symptoms of anemia. The patient may report *early satiety,* or a sense of being full sooner than usual. Anemia, which is common, is caused by chronic blood loss as the lesion erodes through the mucosa or as a result of pernicious anemia (caused by loss of intrinsic factor). The person appears pale and weak and complains of fatigue, weakness, dizziness, and, in extreme cases, shortness of breath. The stool may be positive for occult blood. Supraclavicular lymph nodes that are hard and enlarged suggest metastasis via the thoracic duct. The presence of ascites is a poor prognostic sign.

TABLE 42-19 COLLABORATIVE CARE

Stomach Cancer

Diagnostic

- History and physical examination
- Endoscopy and biopsy
- CT
- Upper GI barium study (less frequent)
- Exfoliative cytologic study
- Endoscopic ultrasonography
- Complete blood count
- Urinalysis
- Stool examination
- Liver enzymes
- Serum amylase
- Tumor markers
  - Carcinoembryonic antigen (CEA)
  - Carbohydrate antigen (CA)–19-9, CA-125, CA 72-4
  - α-Fetoprotein

Collaborative Therapy

- Surgery
  - Subtotal gastrectomy—Billroth I or II procedure (see eFig. 42-1)
  - Total gastrectomy with esophagojejunostomy
- Adjuvant therapy
  - Radiation therapy
  - Chemotherapy
  - Combination radiation therapy and chemotherapy

Diagnostic Studies

The diagnostic studies for stomach cancer are presented in Table 42-19. Upper GI endoscopy is the best diagnostic tool. The stomach can be distended with air during the procedure so that the mucosal folds can be stretched. Biopsy of the tissue and subsequent histologic examination are important for the diagnosis of stomach cancer.

Endoscopic ultrasound, CT, and PET scanning can be used to stage the disease. Barium studies do not always detect small lesions of the cardia and the fundus. Laparoscopy is done to determine peritoneal spread.

Blood chemistry studies detect anemia and determine its severity. Elevations in liver enzymes and serum amylase levels may indicate liver and pancreatic involvement. Stool examination provides evidence of occult or gross bleeding.

Collaborative Care

The treatment of choice for stomach cancer is surgical removal of the tumor. Preoperative management of the patient focuses on the correction of nutritional deficits and treatment of anemia. Transfusions of packed RBCs correct the anemia. If a gastric outlet obstruction occurs, gastric decompression may be necessary before surgery. When the tumor has extended into the transverse colon, partial colon resection is required. Preoperative preparation for bowel surgery includes a low-residue diet, enemas to cleanse the bowel, and antibiotics to reduce the intestinal bacteria. Correction of malnutrition is important if surgery is planned.

Surgical Therapy. The surgical intervention used in the treatment of stomach cancer may be the same surgical procedures used for PUD. The location and extent of the lesion, the patient's physical condition, and the surgeon's preference determine the specific surgery used (e.g., open versus laparoscopic). For patients with localized stomach cancer, surgical treatment alone results in a greater than 50% 5-year survival rate. For patients with lymph node–positive cancer, the 5-year survival rate after surgery is 10% to 50% depending on the degree of spread. Survival rates are less when organs adjacent to the stomach show evidence of invasion at the time of surgery.

The surgical aim is to remove as much of the stomach as necessary to remove the tumor and a margin of normal tissue. When the lesion is located in the fundus, a total gastrectomy with esophagojejunostomy is performed (Fig. 42-16). Lesions located in the antrum or the pyloric region are generally treated by either a Billroth I or II procedure. When metastasis has occurred to adjacent organs, such as the spleen, ovaries, or bowel, the surgical procedure is modified and extended as necessary.

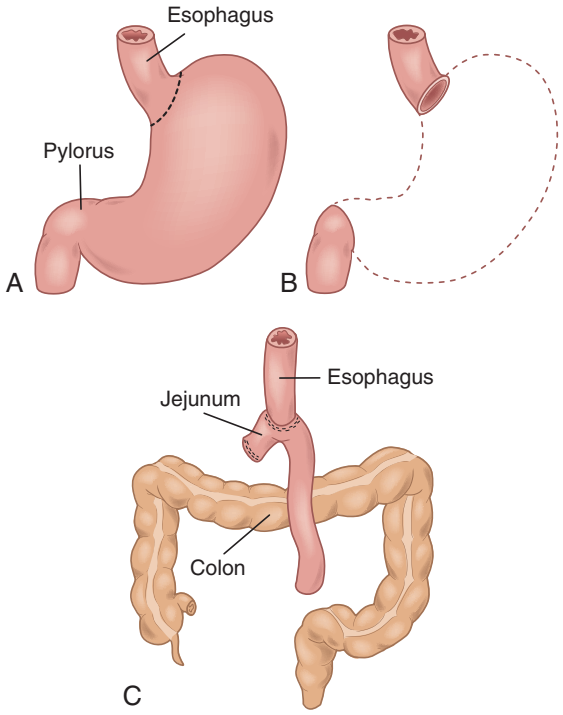

FIG. 42-16 Total gastrectomy for stomach cancer. **A,** Normal anatomic structure of the stomach. **B,** Removal of the stomach (total gastrectomy). **C,** Anastomosis of the esophagus with the jejunum (esophagojejunostomy).

Adjuvant Therapy. The current therapy for localized stomach cancer includes surgical resection and chemotherapy. Agents used in combination include continuous-infusion fluorouracil, epirubicin, cisplatin, etoposide, irinotecan, capecitabine (Xeloda), docetaxel, and oxaliplatin (Eloxatin).

Radiation therapy may be used together with chemotherapy to reduce recurrence and as a palliative measure to decrease tumor mass and provide temporary relief of obstruction. Additional therapies, including intraperitoneal administration of chemotherapeutic agents and immunotherapy, are undergoing evaluation. (These therapies are discussed in Chapter 16.)

NURSING MANAGEMENT STOMACH CANCER

NURSING ASSESSMENT

The assessment of a person with possible stomach cancer is similar to that for PUD (see Table 42-16). Important data to obtain from the patient and the family include a nutritional assessment, a psychosocial history, the patient's perceptions of the health problem and need for care, and a physical examination of the patient.

The nutritional assessment obtains information regarding appetite and changes in eating patterns over the previous 6 months. Determine the patient's normal weight and any recent changes in it. Unexplained weight loss is common. The patient may report a history of vague abdominal symptoms, including dyspepsia and intestinal gas discomfort or pain. If the patient

reports pain, explore where and when it occurs and how it is relieved.

Determine the patient's personal perception of the health problem and method of coping with hospitalization, diagnostic tests, and procedures. The possibility of a diagnosis of cancer and a treatment regimen that may include surgery, chemotherapy, or radiation treatment is stressful.[22] It is important to support the patient and the family. If surgery is probable, assess the patient's expectations regarding surgery (cure or palliation) and how the patient has responded to previous surgical procedures.

Focus your assessment on the patient's current functional abilities, other health problems, and response to therapy. Evaluate the patient's nutritional status. Cachexia may be evident if the nutritional intake has been reduced for an extended period. A malnourished patient does not respond well to chemotherapy or radiation therapy and is a poor surgical risk.

NURSING DIAGNOSES

Nursing diagnoses for the patient with stomach cancer include, but are not limited to, the following:

- Imbalanced nutrition: less than body requirements *related to* inability to ingest, digest, or absorb nutrients
- Anxiety *related to* lack of knowledge of diagnostic tests, unknown diagnostic outcome, disease process, and therapeutic regimen
- Acute pain *related to* underlying disease process and side effects of surgery, chemotherapy, or radiation therapy
- Grieving *related to* perceived unfavorable diagnosis and impending death

PLANNING

The overall goals are that the patient with stomach cancer will (1) experience minimal discomfort, (2) achieve optimal nutritional status, and (3) maintain a degree of spiritual and psychologic well-being appropriate to the disease stage.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Your role in the early detection of stomach cancer is focused on identification of the patient at risk because of specific disorders such as *H. pylori* infection, pernicious anemia, and achlorhydria. Be aware of symptoms associated with stomach cancer, method of spread, and the significant findings on physical examination. Symptoms often occur late and mimic other conditions, such as PUD. Poor appetite, weight loss, fatigue, and persistent stomach distress are symptoms of stomach cancer. Encourage patients who have a positive family history of stomach cancer to undergo diagnostic evaluation if manifestations of anemia, PUD, or vague epigastric distress are present. It is important that you recognize the possible existence of stomach cancer in a patient who is treated for PUD and who fails to have relief after 3 weeks of prescribed therapy.

ACUTE INTERVENTION

Preoperative Care. When the diagnostic tests confirm a malignancy, the patient and the caregiver generally react with shock, disbelief, and depression. Provide emotional and physical support, provide information, clarify test results, and maintain a positive attitude with respect to the patient's immediate recovery and long-term survival.

Because of changes in appetite and early satiety, the patient's current nutritional status may be poor. Surgery may be delayed while the patient becomes more physically able to withstand it. A positive nutritional state enhances wound healing and the ability to deal with infection and other possible postoperative complications. The patient may be better able to tolerate several small meals a day than three regular meals. The diet may be supplemented by a variety of commercial liquid supplements (see Chapter 40) and vitamins. It may be challenging to persuade the patient to eat when he or she has no appetite and is depressed. Getting the patient's caregiver to assist with meals and encourage intake may be beneficial. If the patient is unable to ingest oral feedings, the health care provider may prescribe enteral (tube feeding) or parenteral nutrition.

If needed, packed RBCs and fluid volume restoration may be given during the preoperative period. Closely observe for reactions to the transfusions. Monitor hemoglobin and hematocrit levels.

The preoperative teaching plan before stomach cancer surgery is similar to that for PUD (see the section on surgical therapy for PUD on pp. 949-951).

Postoperative Care. Postoperative care of the patient with stomach cancer is similar to that following a Billroth I or II procedure (see the section on surgical therapy for PUD earlier in this chapter). When the surgical intervention involves a total gastrectomy, the plan of care is somewhat different. A total gastrectomy requires resection of the lower esophagus, removal of the entire stomach, and anastomosis of the esophagus to the jejunum. If the chest cavity is entered, postoperative drainage is accomplished by the insertion of chest tubes. (Chest surgery and drainage tubes are discussed in Chapter 28.)

After total gastrectomy, the NG tube does not drain a large quantity of secretions because removal of the stomach has eliminated the reservoir capacity. The NG tube is removed when intestinal peristalsis has resumed. Small amounts of clear fluid may then be started. Closely observe the patient for signs of leakage of the fluids at the anastomosis site as evidenced by an elevation in the temperature and increasing dyspnea. When the patient tolerates fluids without distress, fluid intake is increased along with the addition of some solid foods.

As a consequence of a total gastrectomy, a patient experiences the symptoms of dumping syndrome. Weight loss often occurs. Postoperative wound healing may be impaired because of poor nutritional intake. This necessitates IV or oral replacement of vitamins C, D, and K; the B-complex vitamins; and cobalamin. Because these vitamins (with the exception of cobalamin) are normally absorbed in the duodenum, they need to be replaced. For the patient who has had a Billroth I or II procedure (see eFig. 42-1 on the website for this chapter), the postoperative care is similar to that of the patient having this procedure for PUD.

Radiation therapy or chemotherapy is used as an adjuvant to surgery or for palliation. Your role is to provide detailed instructions, reassure the patient, and ensure completion of the designated number of treatments. Start by assessing the patient's knowledge of these therapies. Teach the patient about skin care, the need for nutrition and fluid intake during therapy, and the appropriate use of antiemetic drugs. (Specific care of the patient receiving chemotherapy and radiation therapy is discussed in Chapter 16.)

AMBULATORY AND HOME CARE. Most dietary measures useful after PUD surgery are applicable after surgery for stomach cancer. Make plans for the relief of pain, including comfort measures and the judicious use of analgesics. Teach wound care, if needed, to the primary caregiver in the home setting. Dressings, special equipment, or special services may be required for

TABLE 42-20 TYPES OF UPPER GASTROINTESTINAL BLEEDING

Type	Manifestations
Obvious bleeding	
Hematemesis	Bloody vomitus appearing as fresh, bright red blood or "coffee-ground" appearance (dark, grainy digested blood).
Melena	Black, tarry stools (often foul smelling) caused by digestion of blood in the GI tract. Black appearance is from the presence of iron.
Occult bleeding	Small amounts of blood in gastric secretions, vomitus, or stools not apparent by appearance. Detectable by guaiac test.

TABLE 42-21 COMMON CAUSES OF UPPER GASTROINTESTINAL BLEEDING

Drug Induced
- Corticosteroids
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- Salicylates

Esophagus
- Esophageal varices
- Esophagitis
- Mallory-Weiss tear

Stomach and Duodenum
- Stomach cancer
- Hemorrhagic gastritis
- Peptic ulcer disease
- Polyps
- Stress-related mucosal disease

Systemic Diseases
- Blood dyscrasias (e.g., leukemia, aplastic anemia)
- Renal failure

the patient's care at home. Provide the patient with a list of community agencies (e.g., American Cancer Society) that are available for assistance before the patient goes home.

When chemotherapy or radiation treatment is to be continued after discharge, a referral to the home health nurse may be beneficial. The home health nurse can assist with recovery, determine the degree of patient adherence, and provide consultation to the patient and the caregivers. Encourage the patient to adhere to the prescribed therapies, to keep appointments for chemotherapy administration or radiation treatments, and to keep the health care provider informed of changes in physical condition. (Long-term management of the cancer patient is discussed in Chapter 16.)

EVALUATION

Expected outcomes are that the patient with stomach cancer will

- Experience no or minimal discomfort, pain, or nausea
- Achieve optimal nutritional status
- Maintain a degree of psychologic well-being appropriate to the disease stage

UPPER GASTROINTESTINAL BLEEDING

In the United States approximately 300,000 hospital admissions occur each year for upper GI bleeding.[23] Approximately 60% of these are adults over age 65. Despite advances in drug management of predisposing conditions and identification of risk factors, the mortality rate for upper GI bleeding has remained at approximately 6% to 13% for the past 45 years.[23]

Etiology and Pathophysiology

Although the most serious loss of blood from the upper GI tract is characterized by a sudden onset, insidious occult bleeding can also be a major problem. The severity of bleeding depends on whether the origin is venous, capillary, or arterial. (Types of upper GI bleeding are presented in Table 42-20.) Bleeding from an arterial source is profuse, and the blood is bright red, indicating it has not been in contact with gastric HCl acid secretion. In contrast, "coffee-ground" vomitus indicates that the blood has been in the stomach for some time. A massive upper GI hemorrhage is a loss of more than 1500 mL of blood or 25% of intravascular blood volume. *Melena* (black, tarry stools) indicates slow bleeding from an upper GI source. The longer the passage of blood through the intestines, the darker the stool color because of the breakdown of hemoglobin and the release of iron.

Discovering the cause of the bleeding is not always easy. A variety of areas in the GI tract may be involved. Table 42-21 lists the common causes of upper GI bleeding.

Esophageal Origin. Bleeding from the esophagus is most likely due to chronic esophagitis, Mallory-Weiss tear, or esophageal varices. Chronic esophagitis can be caused by GERD, the ingestion of drugs irritating to the mucosa, alcohol, and cigarette smoking. Esophageal varices most often occur secondary to cirrhosis of the liver. (Esophageal varices are discussed in Chapter 44.)

Stomach and Duodenal Origin. Bleeding peptic ulcers account for 40% of the cases of upper GI bleeding. Drugs (either prescription or OTC) are a major cause of upper GI bleeding. Approximately 25% of people on chronic NSAIDs (e.g., ibuprofen) develop endoscopically determined ulcer disease; of these, 2% to 4% will bleed. Aspirin, NSAIDs, and corticosteroids can cause irritation and disruption of the gastroduodenal mucosa. Even low-dose aspirin is associated with risk for GI bleeding. Many OTC preparations contain aspirin. A careful history of all commonly used drugs is necessary whenever upper GI bleeding is suspected.

Stress-related mucosal disease (SRMD), also called *physiologic stress ulcers,* occurs in patients who have had severe burns or trauma or major surgery. In SRMD, there is either diffuse superficial mucosal injury or discrete deeper ulcers in the fundus and body portions of the stomach (see eFig. 42-2 on the website for this chapter). Patients with coagulopathy and those who experience respiratory failure resulting in mechanical ventilation for more than 48 hours are at highest risk.[24]

Diagnostic Studies

Endoscopy is the primary tool for diagnosing the source (e.g., esophageal or gastric varices, gastritis) of upper GI bleeding (see below). Angiography is used in diagnosing upper GI bleeding when endoscopy cannot be done or when bleeding persists after endoscopic therapy. Angiography is an invasive procedure requiring preparation and setup time and may not be appropriate for a high-risk, unstable patient. In this procedure, a catheter is placed into the left gastric or superior mesenteric artery and advanced until the site of bleeding is discovered.

Laboratory studies include CBC, blood urea nitrogen (BUN), serum electrolytes, prothrombin time, partial thromboplastin time, liver enzymes, arterial blood gases (ABGs), and a type and crossmatch for possible blood transfusions. All vomitus and stools should be tested for gross and occult blood.

Monitor the patient's laboratory studies to estimate the effectiveness of therapy. The hemoglobin and hematocrit values are

not of immediate help in estimating the degree of blood loss, but they provide a baseline for guiding further treatment. The initial hematocrit may be normal and may not reflect the loss until 4 to 6 hours after fluid replacement, since initially the loss of plasma and RBCs is equal.

Assess the patient's BUN level. During a significant hemorrhage, blood proteins are broken down by GI tract bacteria, resulting in elevated BUN levels. However, the elevated BUN level may also indicate renal hypoperfusion or renal disease.

Collaborative Care

Although approximately 80% to 85% of patients who have massive hemorrhage spontaneously stop bleeding, the cause must be identified and treatment initiated immediately.

Emergency Assessment and Management. A complete history of events leading to the bleeding episode is deferred until emergency care has been initiated. To facilitate early intervention, the physical examination should focus on early identification of signs and symptoms of shock such as tachycardia, weak pulse, hypotension, cool extremities, prolonged capillary refill, and apprehension. (Shock is discussed in Chapter 67). Monitor vital signs every 15 to 30 minutes.

The patient is at risk for gut perforation and peritonitis, which may be indicated by a tense, rigid, boardlike abdomen. Do a thorough abdominal examination, and note the presence or absence of bowel sounds.

IV lines, preferably two, with a 16- or 18-gauge needle are placed for fluid and blood replacement. The type and amount of fluids infused are dictated by physical and laboratory findings. Generally, an isotonic crystalloid solution (e.g., lactated Ringer's solution) is started. Whole blood, packed RBCs, and fresh frozen plasma may be used for replacement of volume in massive hemorrhage. (The use of blood transfusions and volume expanders is discussed in Chapter 31.)

When upper GI bleeding is less profuse, infusion of isotonic saline solution followed by packed RBCs permits restoration of the hematocrit more quickly and does not create complications related to fluid volume overload. The use of supplemental oxygen delivered by face mask or nasal cannula may help increase blood oxygen saturation.

Urine output is one of the best measures of vital organ perfusion. Therefore an indwelling urinary catheter is inserted so that output can be accurately assessed hourly. A central venous pressure line may be inserted for fluid volume status assessment. If the patient has a history of valvular heart disease, coronary artery disease, or heart failure, a pulmonary artery catheter may be necessary to monitor the patient.

Endoscopic Therapy. The first-line management of upper GI bleeding is endoscopy and endotherapy. Endoscopy performed within the first 24 hours of bleeding is important for diagnosis and the determination of the need for surgical or radiologic intervention.

The goal of endoscopic hemostasis is to coagulate or thrombose the bleeding vessel. Several techniques are used, including (1) thermal (heat) probe, (2) multipolar and bipolar electrocoagulation probe, (3) argon plasma coagulation (APC), and (4) neodymium:yttrium-aluminum-garnet (Nd:YAG) laser. Multipolar electrocoagulation and thermal probe are the two most commonly used procedures. The heat probe coagulates tissue by directly applying a heating element to the bleeding site. The APC is a noncontact coagulation that delivers monopolar current to tissue. For variceal bleeding, other strategies include variceal ligation, injection sclerotherapy, and balloon tamponade (see Chapter 44).

TABLE 42-22 DRUG THERAPY

Acute Gastrointestinal Bleeding*

Drug	Source of GI Bleeding	Mechanism of Action
vasopressin (Pitressin)	Esophageal varices	Causes vasoconstriction. ↓ Pressure in the portal circulation and stops bleeding
octreotide (Sandostatin)	Upper GI bleeding, esophageal varices	Somatostatin analog that ↓ blood flow to GI tract ↓ HCl acid secretion by ↓ release of gastrin
epinephrine	Bleeding from ulceration	Injection during endoscopy produces hemostasis Causes tissue edema and pressure on the source of bleeding Injection therapy often combined with other therapies (e.g., laser)

*Other drugs used to treat GI bleeding are antacids, H_2-receptor blockers, and protein pump inhibitors (see Table 42-9).

Surgical Therapy. Surgical intervention is indicated when bleeding continues regardless of the therapy provided and when the site of the bleeding has been identified. Surgical therapy may be necessary when the patient continues to bleed after rapid transfusion of up to 2000 mL of whole blood or remains in shock after 24 hours. The site of the hemorrhage determines the choice of operation. The mortality rates increase considerably in those over 60 years of age.

Drug Therapy. During the acute phase of upper GI bleeding, empiric PPI therapy with high-dose IV bolus and subsequent infusion is often started before endoscopy. This may decrease the amount of bleeding and the need for endoscopic therapy.

During the acute phase, drugs are used to decrease bleeding, decrease HCl acid secretion, and neutralize the HCl acid that is present. Injection therapy with epinephrine (1:10,000 dilution) during endoscopy is effective for acute hemostasis. Epinephrine produces tissue edema and, ultimately, pressure on the source of bleeding (Table 42-22).

Efforts are made to reduce acid secretion because the acidic environment can alter platelet function and interfere with clot stabilization. PPIs or H_2-receptor blockers are administered IV to decrease acid secretion (see Table 42-10). In patients with upper GI bleeding, somatostatin or its long-acting analog octreotide (Sandostatin) may be administered when endoscopy is not available. Both agents reduce blood flow to the GI organs and acid secretion. After an initial bolus, somatostatin is used for 3 to 7 days, whereas octreotide is given for 3 days after the start of bleeding.

NURSING MANAGEMENT UPPER GASTROINTESTINAL BLEEDING

NURSING ASSESSMENT

A thorough and accurate nursing assessment is an essential first step as you begin care of the patient admitted with upper GI bleeding. The patient may not be able to provide specific information about the cause of the bleeding until immediate physical needs are met. Perform an immediate nursing assessment while

you are getting the patient ready for initial treatment. The assessment includes the patient's level of consciousness, vital signs, skin color, and capillary refill. Check the abdomen for distention, guarding, and peristalsis. Immediate determination of vital signs indicates whether the patient is in shock from blood loss and also provides a baseline blood pressure (BP) and pulse for monitoring the progress of treatment. Signs and symptoms of shock include low BP; rapid, weak pulse; increased thirst; cold, clammy skin; and restlessness. Monitor the patient's vital signs every 15 to 30 minutes, and inform the health care provider of any significant changes.

Once the immediate interventions have begun, the patient or caregiver should answer the following questions: Is there a history of previous bleeding episodes? Has the patient received blood transfusions in the past, and were there any transfusion reactions? Are there any other illnesses (e.g., liver disease, cirrhosis) or medications that may contribute to bleeding or interfere with treatment? Does the patient have a religious preference that prohibits the use of blood or blood products?

Subjective and objective data that should be obtained from the patient or caregiver are presented in Table 42-23.

NURSING DIAGNOSES

Nursing diagnoses for the patient with upper GI bleeding include, but are not limited to, the following:

- Decreased cardiac output *related to* loss of blood
- Deficient fluid volume *related to* acute loss of blood and gastric secretions
- Ineffective peripheral tissue perfusion *related to* loss of circulatory volume
- Anxiety *related to* upper GI bleeding, hospitalization, uncertain outcome, source of bleeding

PLANNING

The overall goals are that the patient with upper GI bleeding will (1) have no further GI bleeding, (2) have the cause of the bleeding identified and treated, (3) experience a return to a normal hemodynamic state, and (4) experience minimal or no symptoms of pain or anxiety.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Although not all cases of upper GI bleeding can be anticipated and prevented, you have an important role in identifying patients at high risk. Always consider the patient with a history of chronic gastritis or PUD at high risk. The patient who has had one major bleeding episode is more likely to have another bleed. Patients with cirrhosis and those with previous upper GI bleeding from varices are also at high risk. Instruct the at-risk patient to avoid gastric irritants such as alcohol and smoking, and to take only prescribed medications. OTC drugs can be harmful because they may contain ingredients (e.g., aspirin) that increase the risk of bleeding. Instruct the patient in the methods of testing vomitus or stools for occult blood. Promptly report positive results to the health care provider.

The patient who requires regular doses of drugs that produce gastroduodenal toxicity (peptic ulcer formation, bleeding), such as aspirin, corticosteroids, or NSAIDs, needs to be taught about the potential for GI bleeding. Patients on daily low-dose aspirin to reduce cardiovascular disease risk are at risk for upper GI bleeding, especially patients over 60 with a history of PUD.

TABLE 42-23 NURSING ASSESSMENT

Upper Gastrointestinal Bleeding

Subjective Data

Important Health Information

Past health history: Precipitating events before bleeding episode, previous bleeding episodes and treatment, peptic ulcer disease, esophageal varices, esophagitis, acute and chronic gastritis, stress-related mucosal disease

Medications: Aspirin, nonsteroidal antiinflammatory drugs, corticosteroids, anticoagulants

Functional Health Patterns

Health perception–health management: Family history of bleeding, smoking, alcohol use

Nutritional-metabolic: Nausea, vomiting, weight loss, thirst

Elimination: Diarrhea; black, tarry stools; decreased urine output; sweating

Activity-exercise: Weakness, dizziness, fainting

Cognitive-perceptual: Epigastric pain, abdominal cramps

Coping–stress tolerance: Acute or chronic stress

Objective Data

General

Fever

Integumentary

Clammy, cool, pale skin; pale mucous membranes, nail beds, and conjunctivae; spider angiomas; jaundice; peripheral edema

Respiratory

Rapid, shallow respirations

Cardiovascular

Tachycardia, weak pulse, orthostatic hypotension, slow capillary refill

Gastrointestinal

Red or "coffee-ground" vomitus; tense, rigid abdomen, ascites; hypoactive or hyperactive bowel sounds; black, tarry stools

Urinary

Decreased urine output, concentrated urine

Neurologic

Agitation, restlessness; decreasing level of consciousness

Possible Diagnostic Findings

↓ Hematocrit and hemoglobin; hematuria; guaiac-positive stools, emesis, or gastric aspirate; ↓ levels of clotting factors; ↑ liver enzymes; abnormal endoscopy results

Even the lowest dose of aspirin can cause GI bleeding. Taking these drugs with meals or snacks lessens their direct irritation. The co-administration of an NSAID with a PPI or high doses of H_2-receptor blocker can reduce bleeding risk. For the patient at risk for gastric ulcers because of NSAID use, misoprostol may also be prescribed. This prostaglandin analog inhibits acid secretion and reduces upper GI bleeding episodes associated with NSAID use. However, the drug has important side effects, including uterine cramping in women, abdominal cramping, and diarrhea.

When you are working with the patient who has a history of liver cirrhosis with esophageal or gastric varices, provide specific instructions on the importance of avoiding known irritants, such as alcohol and smoking. Emphasize the importance of treating an upper respiratory tract infection promptly. Severe

coughing or sneezing can increase pressure on the already fragile varices and may result in massive hemorrhage (see Chapter 44).

Patients with blood dyscrasias (e.g., aplastic anemia) or liver dysfunction or those who are taking cancer chemotherapy drugs are at risk due to a decrease in clotting factors and platelets. Instruct these patients regarding their disease process, drugs, and increased risk of GI bleeding.

ACUTE INTERVENTION. Approach the patient in a calm manner to help decrease the level of anxiety. Use caution when administering sedatives for restlessness because it is one of the warning signs of shock and may be masked by the drugs.

Once an infusion has been started, maintain the IV line for fluid or blood replacement. An accurate intake and output record is essential so that the patient's hydration status can be assessed. Measure the urine output hourly. If the patient has a central venous pressure line or pulmonary artery catheter in place, record these readings every 1 to 2 hours. Hemodynamic monitoring provides an accurate and quick assessment of blood flow and pressure within the cardiovascular system (see Chapter 66).

Observe the older adult or the patient with a history of cardiovascular problems closely for signs of fluid overload. However, volume overload and pulmonary edema are concerns in all patients who are receiving large amounts of IV fluids within a short time. Auscultate breath sounds and closely observe the respiratory effort. Keep the head of the bed elevated to provide comfort and prevent aspiration.

ECG monitoring is also used to evaluate cardiac function. Close monitoring of vital signs, especially in the patient with cardiovascular disease, is important because dysrhythmias may occur.

When an NG tube is inserted, pay special attention to keeping it in proper position and observe the aspirate for blood. Although room-temperature, cool, or iced gastric lavage is used in some institutions, its effectiveness as a treatment for upper GI bleeding is questionable. When lavage is used, approximately 50 to 100 mL of fluid is instilled at a time into the stomach. The lavage fluid may be aspirated from the stomach or drained by gravity. When aspiration is the method used, it is important not to aspirate if resistance is felt. The tip of the NG tube may be up against the gastric mucosal lining. When resistance is a factor, use the gravity method.

Assess the stools for blood (hematochezia, black-tarry, bright red). Black, tarry stools are not usually associated with a brisk hemorrhage but are indicative of prolonged bleeding. Menses and bleeding hemorrhoids should be ruled out as possible sources of blood in the stools. When vomitus contains blood but the stool contains no gross or occult blood, the hemorrhage is considered to have been of short duration.

When oral nourishment is begun, observe the patient for symptoms of nausea and vomiting and a recurrence of bleeding. Feedings initially consist of clear fluids and are given hourly until tolerance is determined. Gradual introduction of foods follows if the patient exhibits no signs of discomfort.

When the hemorrhage is the result of chronic alcohol abuse, closely observe the patient for delirium tremens as withdrawal from alcohol takes place. Symptoms indicating the beginning of delirium tremens are agitation, uncontrolled shaking, sweating, and vivid hallucinations. (Alcohol withdrawal is discussed in Chapter 11.)

AMBULATORY AND HOME CARE. Teach the patient and the caregiver how to avoid future bleeding episodes. Ulcer disease, drug or alcohol abuse, and liver and respiratory diseases can all result in upper GI bleeding. Help the patient and the caregiver be aware of the consequences of not adhering to drug therapy. Emphasize that no drugs (especially aspirin, NSAIDs) other than those prescribed by the health care provider should be taken. Smoking and alcohol should be eliminated because they are sources of irritation and interfere with tissue repair. Long-term follow-up care may be necessary because of possible recurrence. Instruct the patient and family on what to do if an acute hemorrhage occurs in the future.

EVALUATION

The expected outcomes are that the patient with upper GI bleeding will

- Have no upper GI bleeding
- Maintain normal fluid volume
- Experience a return to a normal hemodynamic state
- Understand potential etiologic factors and make appropriate lifestyle modifications

FOODBORNE ILLNESS

Foodborne illness (food poisoning) is a nonspecific term that describes acute GI symptoms such as nausea, vomiting, diarrhea, and cramping abdominal pain caused by the intake of contaminated food or liquids.[25] There are 31 known foodborne pathogens. Each year one out of six Americans, approximately 48 million, experiences a foodborne illness. Of these, 128,000 are hospitalized and approximately 3000 die.[26]

Bacteria account for most of the foodborne illnesses. Raw foods that have become contaminated during growing, harvesting, processing, storing, shipping, or final preparation are the most common source. When food is uncooked and left out for more than 2 hours at room temperature, bacteria can multiply quickly. One example is prepackaged cookie dough. The most common bacterial food poisonings are presented in Table 42-24.

Focus interventions on prevention of infection. Teaching includes correct food preparation and cleanliness, adequate cooking, and refrigeration (Table 42-25). For the hospitalized patient, emphasize correction of fluid and electrolyte imbalance from diarrhea and vomiting. With botulism, additional assessment and care relative to neurologic symptoms are indicated (see Chapter 61).

Escherichia coli O157:H7 Poisoning

Escherichia coli O157:H7 causes hemorrhagic colitis and kidney failure. In the very young and older adults, *E. coli* O157:H7 can be life threatening. *E. coli* O157:H7 is found primarily in undercooked meats, particularly poultry and hamburger.[26] *E. coli* outbreaks have also been observed with contaminated leafy vegetables, fruits, and nuts. Person-to-person contact in families, nursing homes, and child care centers is also an important mode of transmission. Infection can also occur after drinking raw milk, unpasteurized juice, or contaminated fruit juices and after swimming in or drinking sewage-contaminated water.

Most strains of *E. coli* are harmless and live in the intestines of healthy humans and animals. *E. coli* O157:H7 produces a

TABLE 42-24 BACTERIAL FOOD POISONING

Type and Cause	Sources	Clinical Manifestations	Treatment and Prevention
Staphylococcal Toxin from *Staphylococcus aureus*	Meat, bakery products, cream fillings, salad dressings, milk. Skin and respiratory tract of food handlers	*Onset:* 30 min–7 hr Vomiting, nausea, abdominal cramping, diarrhea	*Treat:* Symptomatic, fluid and electrolyte replacement, antiemetics *Prevent:* Immediate refrigeration of foods, monitoring of food handlers
Clostridial *Clostridium perfringens*	Meat or poultry dishes cooked at lower temperature (stew, pot pie), rewarmed meat dishes, gravies, improperly canned vegetables	*Onset:* 8-24 hr Diarrhea, nausea, abdominal cramps, vomiting (rare), midepigastric pain	*Treat:* Symptomatic, fluid replacement *Prevent:* Correct preparation of meat dishes. Serving food immediately after cooking or rapid cooling of food
Salmonella *Salmonella typhimurium* (grows in gut)	Improperly cooked poultry, pork, beef, lamb, and eggs	*Onset:* 8 hr–several days Nausea and vomiting, diarrhea, abdominal cramps, fever and chills	*Treat:* Symptomatic, fluid and electrolyte replacement *Prevent:* Correct preparation of food
Botulism Toxin from *Clostridium botulinum;* ingested toxin absorbed from gut and blocks acetylcholine at neuromuscular junction	Improperly canned or preserved food, home-preserved vegetables (most common), preserved fruits and fish, canned commercial products	*Onset:* 12-36 hr *GI:* Nausea, vomiting, abdominal pain, constipation, distention *Central nervous system:* Headache, dizziness, muscular incoordination, weakness, inability to talk or swallow, diplopia, breathing difficulties, paralysis, delirium, coma	*Treat:* Maintenance of ventilation, polyvalent antitoxin, guanidine hydrochloric acid (enhances acetylcholine release) *Prevent:* Correct processing of canned foods, boiling of suspected canned foods for 15 min before serving
Escherichia coli *E. coli* O157:H7	Contaminated beef, pork, milk, cheese, fish, cookie dough	*Onset:* 8 hr–1 wk (varies by strain) Bloody stools, hemolytic uremic syndrome, abdominal cramping, profuse diarrhea	*Treat:* Symptomatic, fluid and electrolyte replacement *Prevent:* Correct preparation of food

TABLE 42-25 PATIENT & CAREGIVER TEACHING GUIDE

Prevention of Food Poisoning

Include the following instructions when teaching the patient and caregiver how to prevent food poisoning.

1. Cook all ground beef and hamburger thoroughly.
   - Use a digital instant-read meat thermometer to ensure thorough cooking (ground beef can turn brown before disease-causing bacteria are killed).
   - Cook ground beef until a thermometer inserted into several parts of the patty, including the thickest part, reads at least 160° F.
   - People who cook ground beef without using a thermometer can decrease their risk of illness by not eating ground beef patties that are still pink in the middle.
2. If you are served an undercooked hamburger or other ground beef product in a restaurant, send it back for further cooking. Also ask for a new bun and a clean plate.
3. Avoid spreading harmful bacteria. Keep raw meat separate from ready-to-eat foods. Wash hands, counters, and utensils with hot soapy water after they touch raw meat. Never place cooked hamburgers or ground beef on the unwashed plate that held raw patties. Wash meat thermometers in between tests of patties that require further cooking.
4. Drink only pasteurized milk, juice, or cider. Commercial juice with an extended shelf-life that is sold at room temperature (e.g., juice in cardboard boxes, vacuum-sealed juice in glass containers) has been pasteurized. Juice concentrates are also heated sufficiently to kill pathogens.
5. Wash fruits and vegetables thoroughly, especially those that will not be cooked.
6. Do not eat raw food products that are supposed to be cooked. Follow package directions for cooking at proper temperatures.
7. People who are immunocompromised or older adults should avoid eating alfalfa sprouts until the safety of the sprouts can be ensured.

powerful toxin and can cause severe illness. The clinical manifestations of *E. coli* O157:H7 include diarrhea (often bloody) and abdominal cramping pain for 2 to 8 days (average 3 to 4 days) after swallowing the organism. The diarrhea is variable, ranging from mild to bloody. The diarrhea may start out as watery but may progress to bloody. Systemic complications, including hemolytic uremia and thrombocytopenic purpura, and even death can occur.

Infection with *E. coli* O157:H7 is diagnosed by detecting the bacteria in the stool. All people who suddenly have diarrhea with blood should get their stool (stool culture) tested for *E. coli* O157:H7.

Treatment involves supportive care to maintain blood volume. The use of antibiotics remains controversial. Most people recover without antibiotics or other specific treatment. There is no evidence that antibiotics improve the course of disease, and it is thought that treatment with some antibiotics may precipitate kidney complications. Patients should avoid antidiarrheal agents, such as loperamide (Imodium). Other therapies may include dialysis and plasmapheresis.

In approximately 2% to 7% of infections, particularly in young children and older adults, hemolytic uremic syndrome (HUS) occurs, in which the RBCs are destroyed and the kidneys fail. HUS is a life-threatening condition usually treated in an ICU. Blood transfusions and kidney dialysis are often required. Approximately 3% to 5% of patients with HUS die. About one third of people with HUS have abnormal kidney function many years later, and a few require long-term dialysis. Additional long-term complications of HUS include hypertension, seizures, blindness, and paralysis.

CASE STUDY

Peptic Ulcer Disease

iStockphoto/Thinkstock

Patient Profile

F.H., a 40-yr-old male immigrant from Vietnam, has a 1-yr history of epigastric distress. Increasingly, it is not relieved by over-the-counter antacids and cimetidine (Tagamet). He is scheduled for an upper endoscopy this morning.

Subjective Data

- Reports increasing substernal pain, especially 2 to 3 hr after eating
- Currently avoids alcohol and is taking antacids and over-the-counter H_2-receptor blocker
- Smoking history of 1 pack of cigarettes per day for 20 yr
- Complains of increasing fatigue with exercise
- Reports occasional black bowel movement
- Takes Chinese medicine for frequent back pain

Objective Data

Physical Examination

- Height 5 ft, 5 in tall and weight 140 lb

Diagnostic Studies

- Endoscopy reveals a duodenal ulcer
- Hgb 10.2 g/dL; Hct 30%
- Histology of biopsied tissue reveals *Helicobacter pylori* infection

Collaborative Care

- omeprazole 20 mg bid × 10 days
- clarithromycin 500 mg bid × 10 days
- amoxicillin 1 g bid × 10 days

Discussion Questions

1. Explain the pathophysiology of peptic ulcer disease.
2. What are the risk factors for duodenal ulcers? Which of these did F.H. have?
3. What is the pathophysiology of *H. pylori?*
4. What lifestyle changes would you recommend for F.H.?
5. ***Priority Decision:*** What are the priority nursing interventions for F.H.?
6. ***Delegation Decision:*** For the interventions that you identified in question 5, which of the following personnel could be responsible for implementing them: registered nurse (RN), licensed practical nurse (LPN), unlicensed assistive personnel (UAP)?
7. ***Priority Decision:*** Based on the assessment data provided, what are the priority nursing diagnoses? Are there any collaborative problems?
8. ***Evidence-Based Decision:*** F.H. asks you if the treatment will work and this will be the end of his problems. How will you respond?

evolve Answers available at http://evolve.elsevier.com/Lewis/medsurg.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. M.J. calls to tell the nurse that her 85-year-old mother has been nauseated all day and has vomited twice. Before the nurse hangs up and calls the health care provider, she should instruct M.J. to
   a. administer antispasmodic drugs and observe skin turgor.
   b. give her mother sips of water and elevate the head of her bed to prevent aspiration.
   c. offer her mother a high-protein liquid supplement to drink to maintain her nutritional needs.
   d. offer her mother large quantities of Gatorade to drink because older adults are at risk for sodium depletion.
2. The nurse explains to the patient with Vincent's infection that treatment will include
   a. smallpox vaccinations.
   b. viscous lidocaine rinses.
   c. amphotericin B suspension.
   d. topical application of antibiotics.
3. The nurse teaching young adults about behaviors that put them at risk for oral cancer includes
   a. discouraging use of chewing gum.
   b. avoiding use of perfumed lip gloss.
   c. avoiding use of smokeless tobacco.
   d. discouraging drinking of carbonated beverages.
4. The nurse explains to the patient with gastroesophageal reflux disease (GERD) that this disorder
   a. results in acid erosion of the esophagus from frequent vomiting.
   b. will require surgical wrapping or repair of the pyloric sphincter to control the symptoms.
   c. is the protrusion of a portion of the stomach into the esophagus through an opening in the diaphragm.
   d. often involves relaxation of the lower esophageal sphincter, allowing stomach contents to back up into the esophagus.
5. A patient who has undergone an esophagectomy for esophageal cancer develops increasing pain, fever, and dyspnea when a full liquid diet is started postoperatively. The nurse recognizes that these symptoms are most indicative of
   a. an intolerance to the feedings.
   b. extension of the tumor into the aorta.
   c. leakage of fluid or foods into the mediastinum.
   d. esophageal perforation with fistula formation into the lung.
6. The pernicious anemia that may accompany gastritis is due to
   a. chronic autoimmune destruction of cobalamin stores in the body.
   b. progressive gastric atrophy from chronic breakage in the mucosal barrier and blood loss.
   c. a lack of intrinsic factor normally produced by acid-secreting cells of the gastric mucosa.
   d. hyperchlorhydria resulting from an increase in acid-secreting parietal cells and degradation of RBCs.
7. The nurse is teaching the patient and family that peptic ulcers are
   a. caused by a stressful lifestyle and other acid-producing factors such as *H. pylori*.
   b. inherited within families and reinforced by bacterial spread of *Staphylococcus aureus* in childhood.
   c. promoted by factors that tend to cause oversecretion of acid, such as excess dietary fats, smoking, and *H. pylori*.
   d. promoted by a combination of factors that may result in erosion of the gastric mucosa, including certain drugs and alcohol.
8. An optimal teaching plan for an outpatient with stomach cancer receiving radiation therapy should include information about
   a. cancer support groups, alopecia, and stomatitis.
   b. avitaminosis, ostomy care, and community resources.
   c. prosthetic devices, skin conductance, and grief counseling.
   d. wound and skin care, nutrition, drugs, and community resources.

9. The teaching plan for the patient being discharged after an acute episode of upper GI bleeding includes information concerning the importance of *(select all that apply)*
   a. only taking aspirin with milk or bread products.
   b. avoiding taking aspirin and drugs containing aspirin.
   c. only taking drugs prescribed by the health care provider.
   d. taking all drugs 1 hour before mealtime to prevent further bleeding.
   e. reading all OTC drug labels to avoid those containing stearic acid and calcium.

10. Several patients are seen at an urgent care center with symptoms of nausea, vomiting, and diarrhea that began 2 hours ago while attending a large family reunion potluck dinner. You question the patients specifically about foods they ingested containing
    a. beef.
    b. meat and milk.
    c. poultry and eggs.
    d. home-preserved vegetables.

1. b, 2. d, 3. c, 4. d, 5. c, 6. c, 7. d, 8. d, 9. b, c, 10. b

LEARNING OUTCOMES

1. Explain the common etiologies, collaborative care, and nursing management of diarrhea, fecal incontinence, and constipation.
2. Describe common causes of acute abdominal pain and nursing management of the patient after an exploratory laparotomy.
3. Describe the collaborative care and nursing management of acute appendicitis, peritonitis, and gastroenteritis.
4. Compare and contrast the inflammatory bowel diseases of ulcerative colitis and Crohn's disease, including pathophysiology, clinical manifestations, complications, collaborative care, and nursing management.
5. Differentiate among mechanical and nonmechanical bowel obstructions, including causes, collaborative care, and nursing management.
6. Describe the clinical manifestations and collaborative management of colorectal cancer.
7. Explain the anatomic and physiologic changes and nursing management of the patient with an ileostomy and a colostomy.
8. Differentiate between diverticulosis and diverticulitis, including clinical manifestations, collaborative care, and nursing management.
9. Compare and contrast the types of hernias, including etiology and surgical and nursing management.
10. Describe the types of malabsorption syndromes and collaborative care of celiac disease, lactase deficiency, and short bowel syndrome.
11. Describe the types, clinical manifestations, collaborative care, and nursing management of anorectal conditions.

Reviewed by Carmen Bruni, RN, MSN, Nurse Executive, Assistant Professor of Nursing, Texas A & M International University, Laredo, Texas.

The wide variety of intestinal problems presented in this chapter include the disorders of diarrhea, fecal incontinence, and constipation; inflammatory and infectious bowel disorders; bowel trauma; bowel obstructions; colorectal cancer; abdominal and bowel surgery (including ostomy formation); and malabsorption disorders.

DIARRHEA

Diarrhea is the passage of at least three loose or liquid stools per day. It may be acute, or it is considered chronic if it lasts longer than 4 weeks.[1]

Etiology and Pathophysiology

Ingestion of infectious organisms is the primary cause of acute diarrhea (Table 43-1). Viruses cause most cases of infectious diarrhea in the United States. Although viral infections can be deadly, they are usually short lived (48 hours) and mild. Therefore most patients rarely seek treatment.

TABLE 43-1 CAUSES OF ACUTE INFECTIOUS DIARRHEA*

Type of Organism	Symptoms
Viral	
Rotavirus *(e.g., Rotavirus A)*	Fever, vomiting, profuse watery diarrhea. Lasts 3-8 days.
Norovirus (also called Norwalk-like virus)	Nausea, vomiting, diarrhea, stomach cramping. Rapid onset. Lasts 1-2 days.
Bacterial	
Enterotoxigenic *Escherichia coli*	Watery or bloody diarrhea. Abdominal cramps. Nausea, vomiting, and fever may be present. Mean duration >60 hr.
Enterohemorrhagic *E. coli* (e.g., *E. coli* O157:H7)	Severe abdominal cramping, bloody diarrhea, vomiting. Low-grade fever. Usually lasts 5-7 days.
Shigella	Diarrhea (sometimes bloody), fever, stomach cramps. Usually lasts 5-7 days. Postinfection arthritis may occur.
Salmonella	Diarrhea, fever, abdominal cramps. Lasts 4-7 days.
Staphylococcus	Nausea, vomiting, abdominal cramps, diarrhea. Usually mild. May cause illness in as little as 30 min. Lasts 1-3 days.
Campylobacter jejuni	Diarrhea, abdominal cramps, fever. Sometimes nausea and vomiting. Lasts about 7 days.
Clostridium perfringens	Diarrhea, abdominal cramps, nausea, vomiting. Occurs 8-24 hr after eating contaminated food and lasts approximately 24 hr.
Clostridium difficile	Watery diarrhea, fever, anorexia, nausea, abdominal pain.
Parasitic	
Giardia lamblia	Abdominal cramps, nausea, diarrhea. May interfere with nutrient absorption.
Entamoeba histolytica	Diarrhea, abdominal cramping. Only 10%-20% are ill, and symptoms are usually mild.
Cryptosporidium	Watery diarrhea. Lasts about 2 wk. May also have abdominal cramps, nausea, vomiting, fever, dehydration, and weight loss. Sometimes no symptoms. Long lasting and may be fatal in those who are immunocompromised (e.g., AIDS).

*An expanded version of this table (eTable 43-1) with source of infection and drug treatment is available on the website for this chapter.

Bacterial infections are also common.[2] *Escherichia coli* O157:H7, a type of enterohemorrhagic *E. coli,* is the most common cause of bloody diarrhea in the United States. It is transmitted by inadequately cooked beef or chicken contaminated with the bacteria or in fruits and vegetables exposed to contaminated manure. Other pathologic *E. coli* strains are endemic in developing countries and are common causes of traveler's diarrhea. *Giardia lamblia* is the most common intestinal parasite that causes diarrhea in the United States.

Infectious organisms attack the intestines in different ways.[3] Some organisms (e.g., *Rotavirus A, Norovirus, G. lamblia*) alter secretion and/or absorption of the enterocytes of the small intestine without causing inflammation. Other organisms (e.g., *Clostridium difficile*) impair absorption by destroying cells, cause inflammation in the colon, and produce toxins that also cause damage.

Organisms enter the body in contaminated food (e.g., *Salmonella* organisms in undercooked eggs and chicken) or contaminated drinking water (*G. lamblia* in contaminated lakes or pools). Travelers often get diarrhea, especially if they travel to countries with poorer sanitation than their own. An infection can also be transmitted from one individual to another via the fecal-oral route. For example, adult day care workers can transmit infection from one resident to another if they do not wash their hands thoroughly after changing soiled linen.

An individual's susceptibility to pathogenic organisms is influenced by age, gastric acidity, intestinal microflora, and immunocompetence. Older adults are most likely to suffer life-threatening diarrhea. Since stomach acid kills ingested pathogens, medications designed to decrease stomach acid (e.g., proton pump inhibitors and histamine [H_2]-receptor blockers) increase the likelihood that pathogens will survive.[4]

The healthy human colon contains short-chain fatty acids and bacteria such as *E. coli.* These organisms aid in fermentation and provide a microbial barrier against pathogenic bacteria. Antibiotics kill off the normal flora, making the individual more susceptible to pathogenic organisms. For example, patients receiving broad-spectrum antibiotics (e.g., clindamycin [Cleocin], cephalosporins, fluoroquinolones) are susceptible to pathogenic strains of *C. difficile. C. difficile* is the most serious antibiotic-associated diarrhea and is becoming more prevalent. Probiotics, in particular *Saccharomyces boulardii* and *Lactobacillus,* may be helpful in preventing antibiotic-induced diarrhea in some patients.

People who are immunocompromised because of disease (e.g., human immunodeficiency virus [HIV]) or immunosuppressive medications are susceptible to gastrointestinal (GI) tract infection. Patients who are immunocompromised and receiving jejunal enteral nutrition are especially prone to *C. difficile* and other foodborne infections. Jejunostomy and nasointestinal feedings, which bypass the stomach's acid environment, do not contain the poorly digestible fiber that is necessary for the survival of normal colonic bacteria.[5]

Not all diarrhea is due to infection. For example, drugs and specific food intolerances can cause diarrhea. Also, large amounts of undigested carbohydrate in the bowel produce an osmotic diarrhea that promotes rapid transit and prevents absorption of fluid and electrolytes. Lactose intolerance and certain laxatives (e.g., lactulose, sodium phosphate, magnesium

citrate) produce an osmotic diarrhea. Bile salts and undigested fats also lead to excessive fluid secretion in the GI tract. The diarrhea from celiac disease and short bowel syndrome results from malabsorption in the small intestine.

Clinical Manifestations

Infections that attack the upper GI tract (e.g., *Norovirus*, *G. lamblia*) usually produce large-volume, watery stools; cramping; and periumbilical pain. Patients have either a low-grade or no fever and often experience nausea and vomiting before the diarrhea begins. Infections of the colon and distal small bowel (e.g., *Shigella, Salmonella, C. difficile*) produce fever and frequent bloody diarrhea with a small volume.

Leukocytes, blood, and mucus may be present in the stool, depending on the causative agent (see Table 43-1). Severe diarrhea produces life-threatening dehydration, electrolyte disturbances (e.g., hypokalemia), and acid-base imbalances (metabolic acidosis). *C. difficile* infection can progress to fulminant colitis and intestinal perforation.

Diagnostic Studies

Since most cases of diarrhea resolve quickly, stool cultures are indicated only for patients who are very ill, have a significant fever, or have had diarrhea longer than 3 to 5 days. Stools are examined for blood, mucus, white blood cells (WBCs), and parasites, and cultures are performed to identify infectious organisms. A multiple-pathogen test can simultaneously detect 11 common viral, bacterial, and parasitic causes of infectious gastroenteritis from a single patient sample. Toxins produced by *C. difficile* can usually be detected in a sample of a patient's stool.

Testing for ova and parasites is reserved for people who have had diarrhea more than 2 weeks. The WBC count may be elevated. People with long-standing diarrhea can develop anemia from iron and folate deficiencies. Increased hematocrit, blood urea nitrogen (BUN), and creatinine levels are signs of fluid deficit.

In patients with chronic diarrhea, measurements of stool electrolytes, pH, and osmolality help determine whether the diarrhea is related to decreased fluid absorption or increased fluid secretion. Measurement of stool fat and undigested muscle fibers may indicate fat and protein malabsorption conditions, including pancreatic insufficiency. Some patients with secretory diarrhea have elevated serum levels of GI hormones such as vasoactive intestinal polypeptide and gastrin.

Collaborative Care

Treatment depends on the cause. Foods and drugs that cause diarrhea should be avoided. Acute infectious diarrhea is usually self-limiting. The major concerns are preventing transmission, replacing fluid and electrolytes, and protecting the skin. Patients usually tolerate oral fluids. Solutions containing glucose and electrolytes (e.g., Pedialyte) may be sufficient to replace losses from mild diarrhea. Parenteral administration of fluids, electrolytes, vitamins, and nutrition is necessary if losses are severe.

Antidiarrheal agents are sometimes given to coat and protect mucous membranes, absorb irritating substances, inhibit intestinal transit, decrease intestinal secretions, or decrease central nervous system stimulation of the GI tract (Table 43-2). Antidiarrheal agents are contraindicated in the treatment of some infectious diarrheas because they potentially prolong exposure to the organism. They are used cautiously in inflammatory bowel disease (IBD) because of the danger of *toxic megacolon* (colonic dilation greater than 5 cm). Regardless of the cause of diarrhea, antidiarrheal drugs should be given only for a short time.

TABLE 43-2 DRUG THERAPY

Antidiarrheal Drugs

Drug	Mechanism of Action
bismuth subsalicylate (Pepto-Bismol)	Decreases secretions and has weak antibacterial activity. Used to prevent traveler's diarrhea.
calcium polycarbophil (Mitrolan)	Bulk-forming agent that absorbs excessive fluid from diarrhea to form a gel. Used when intestinal mucosa cannot absorb fluid.
loperamide (Imodium, Pepto Diarrhea Control)	Inhibits peristalsis, delays transit, increases absorption of fluid from stools.
diphenoxylate with atropine (Lomotil)	Opioid and anticholinergic. Decreases peristalsis and intestinal motility.
paregoric (camphorated tincture of opium)	Opioid. Decreases peristalsis and intestinal motility.
Donnagel-PG (combination of kaolin, pectin, and paregoric)	Decreases peristalsis and intestinal motility.
octreotide acetate (Sandostatin)	Suppresses serotonin secretion, stimulates fluid absorption from GI tract, decreases intestinal motility.

Antibiotics are rarely used to treat acute diarrhea. However, they may be used for certain infections or when the infected individual is severely ill or immunosuppressed. For example, a nonabsorbable antibiotic, rifaximin (Xifaxan), is used to treat traveler's diarrhea that is caused by *E. coli*.

***Clostridium difficile* Infection.** *C. difficile* infection is a particularly hazardous health care–associated infection. Its spores can survive for up to 70 days on objects, including commodes, telephones, thermometers, bedside tables, and floors. *C. difficile* can be transmitted from patient to patient by health care workers who do not adhere to infection control precautions.

The infection is usually treated by stopping antibiotics and starting the patient on either metronidazole (Flagyl) or vancomycin (Vancocin). Metronidazole is the first line of treatment in mild disease because of concerns about vancomycin-resistant enterococcus (VRE). Since recovery rates are substantially better with vancomycin, it is preferred for serious infections. Both drugs are given orally, but metronidazole may also be given IV. Fidaxomicin (Dificid) is generally reserved for patients who are at risk for relapse or have recurrent infections.

Recurrent *C. difficile* infection occurs in about 20% of patients, and the probability of a recurrence rises with each subsequent infection. Feces transplantation is under investigation as a potential therapeutic option for patients with recurrent and resistant *C. difficile* infections.[6] In this procedure healthy person's feces are inserted into the GI tract using an enema or nasogastric tube, or during colonoscopy.

NURSING MANAGEMENT ACUTE INFECTIOUS DIARRHEA

NURSING ASSESSMENT

Begin the nursing assessment with a thorough history and physical examination (Table 43-3). Ask the patient to describe his or her stool pattern and associated symptoms. Focus on the

TABLE 43-3 NURSING ASSESSMENT

Diarrhea

Subjective Data

Important Health Information

Past health history: Recent travel, infections, stress; diverticulitis or malabsorption; metabolic disorders; inflammatory bowel disease; irritable bowel syndrome

Medications: Laxatives or enemas, magnesium-containing antacids, sorbitol-containing suspensions or elixirs, antibiotics, methyldopa, digitalis, colchicine; OTC antidiarrheal medications

Surgery or other treatments: Stomach or bowel surgery, radiation

Functional Health Patterns

Health perception–health management: Chronic laxative abuse, malaise

Nutritional-metabolic: Ingestion of fatty and spicy foods, food intolerances; anorexia, nausea, vomiting; weight loss; thirst

Elimination: Increased stool frequency, volume, and looseness; change in color and character of stools; steatorrhea, abdominal bloating; decreased urine output

Cognitive-perceptual: Abdominal tenderness, abdominal pain and cramping; tenesmus

Objective Data

General

Lethargy, sunken eyeballs, fever, malnutrition

Integumentary

Pallor, dry mucous membranes, poor skin turgor, perianal irritation

Gastrointestinal

Frequent soft to liquid stools that may alternate with constipation; altered stool color; abdominal distention, hyperactive bowel sounds; pus, blood, mucus, or fat in stools; fecal impaction

Urinary

Decreased output, concentrated urine

Possible Diagnostic Findings

Abnormal serum electrolyte levels; anemia; leukocytosis; eosinophilia, hypoalbuminemia; positive stool cultures; ova, parasites, leukocytes, blood, or fat in stool; abnormal sigmoidoscopy or colonoscopy findings; abnormal lower GI series

duration, frequency, character, and consistency of stool, and the relationship to other symptoms such as pain and vomiting. Inquire about medical conditions that might cause diarrhea and whether the person is taking medications such as antibiotics and laxatives that are known to cause diarrhea, decrease stomach acidity, or cause immunosuppression. Determine whether the patient has traveled to a foreign country or been at a day care facility recently and if family members are also ill. Ask about food preparation practices, food intolerances (e.g., milk), and changes in diet and appetite.

Assess for fever and signs of dehydration (dry skin, low-grade fever, orthostatic changes to pulse and blood pressure, decreased and concentrated urine). Assess the abdomen for distention, pain, and guarding. Inspect the perineal skin for signs of redness and breakdown from the diarrhea.

NURSING DIAGNOSES

Nursing diagnoses for the patient with acute infectious diarrhea may include, but are not limited to, the following:

- Diarrhea *related to* acute infectious process
- Deficient fluid volume *related to* excessive fluid loss and decreased fluid intake

Additional information on nursing diagnoses is presented in eNursing Care Plan 43-1 on the website for this chapter.

PLANNING

The overall goals are that the patient with diarrhea will have (1) no transmission of the microorganism causing the infectious diarrhea; (2) cessation of diarrhea and resumption of normal bowel patterns; (3) normal fluid, electrolyte, and acid-base balance; (4) normal nutritional status; and (5) no perianal skin breakdown.

NURSING IMPLEMENTATION

Consider all cases of acute diarrhea as infectious until the cause is known. Strict infection control precautions are necessary to prevent the illness from spreading to others (see eTable 15-1 on the website for Chapter 15 for CDC Isolation Precautions). Wash your hands before and after contact with each patient and when handling body fluids of any kind. Flush vomitus and stool in the toilet. Teach the patient and caregiver to wash contaminated clothing immediately with soap and water. Also teach them the principles of hygiene, infection control precautions, and the potential dangers of an illness that is infectious to themselves and others. Discuss proper food handling, cooking, and storage with the patient and the caregiver (see Chapter 42, Table 42-24).

Viruses and *C. difficile* spores are extremely difficult to kill. Alcohol-based hand cleaners and ammonia-based disinfectants are ineffective, and even vigorous cleaning with soap and water does not kill everything. Provide private rooms for patients with *C. difficile* infection, and ensure that visitors and health care providers wear gloves and gowns. Infected patients must be given their own disposable stethoscopes and thermometers. Consider all objects in the room contaminated, and ensure they are disinfected with a 10% solution of household bleach.

FECAL INCONTINENCE

Etiology and Pathophysiology

Fecal incontinence is the involuntary passage of stool. It occurs when the normal structures that maintain continence are disrupted. Defecation is a voluntary action when the neuromuscular system is intact (see Chapter 39). Problems with motor function (contraction of sphincters and rectal floor muscles) and/or sensory function (ability to perceive the presence of stool or to experience the urge to defecate) can result in fecal incontinence. Contributing factors to incontinence include weakness or disruption of the internal or external anal sphincter, damage to the pudendal nerve or other nerves that innervate the anorectum, damage to the anal tissue, and trauma to the puborectalis muscle.[7]

For women, obstetric trauma is the most common cause of sphincter disruption. Childbirth, aging, and menopause contribute to the development of fecal incontinence. Other risk factors are listed in Table 43-4. With diarrhea, the likelihood is increased that stool will be accidentally discharged. Chronic constipation can lead to *fecal impaction* (the accumulation of hardened feces in the rectum or sigmoid colon that cannot be expelled). Incontinence occurs as liquid stool seeps around the hardened feces. Fecal impaction is a common problem in older adults with limited mobility. Constipated individuals tend to strain during defecation. Straining contributes to incontinence because it weakens the pelvic floor muscles.

TABLE 43-4 CAUSES OF FECAL INCONTINENCE

Traumatic
- Anorectal surgery for hemorrhoids, fistula, and fissures
- Childbirth injury (episiotomy is a risk factor)
- Perineal trauma or pelvic fracture

Neurologic
- Brain tumor
- Cauda equina nerve injury
- Congenital abnormalities (e.g., spina bifida, myelomeningocele)
- Dementia
- Diabetes mellitus (secondary to neuropathy)
- Multiple sclerosis
- Rectal surgery
- Spinal cord injuries
- Stroke

Inflammatory
- Infection
- Inflammatory bowel disease
- Radiation

Pelvic Floor Dysfunction
- Medications
- Rectal prolapse

Functional
- Physical or mobility impairments affecting toileting ability (e.g., frail older person who cannot get to the bathroom in time)

Other
- Chronic constipation
- Denervation of pelvic muscles from chronic excessive straining
- Fecal impaction
- Loss of rectal elasticity
- Rapid transit of large diarrheal stools

Anorectal surgery such as hemorrhoidectomy and colectomy can damage the sphincters and pudendal nerves. Radiation for prostate cancer decreases rectal compliance. Neurologic conditions, including stroke, spinal cord injury, multiple sclerosis, Parkinson's disease, and diabetic neuropathy, also interfere with defecation. Even people with normally functioning defecation experience incontinence if immobility prevents timely access to a toilet.

Diagnostic Studies and Collaborative Care

The diagnosis and effective management of fecal incontinence require a thorough health history and physical examination. Ask the patient about the number of incontinent episodes per week, stool consistency and volume, and the degree that incontinence interferes with work and social activities. A rectal examination can reveal reduced anal canal muscle tone and contraction strength of the external sphincter, as well as detect internal prolapse, rectocele, hemorrhoids, fecal impaction, and masses. If the impaction is higher in the colon, an abdominal x-ray or a computed tomography (CT) scan may be helpful. Other tests include anorectal manometry, anorectal ultrasonography, and defecography. Sigmoidoscopy or colonoscopy is used to identify inflammation, tumors, fissures, and other pathologic conditions.

Treatment of incontinence depends on the underlying cause. Fecal incontinence from fecal impaction usually resolves after manual disimpaction of the hard feces and cleansing enemas. To prevent recurrence, normal stool consistency is maintained with a bowel management program that includes regular defecation practices, a high-fiber diet, and increased fluid intake. Damage to the anal sphincters may require surgical repair.

Dietary fiber supplements or bulk-forming laxatives such as psyllium in Metamucil increase stool bulk, firm stool consistency, and promote the sensation of rectal filling. Intake of foods that cause diarrhea and rectal irritation may need to be reduced or eliminated. For some patients this may include coffee, dried fruit, onions, mushrooms, green vegetables, fruit with peels, spicy foods, and foods with monosodium glutamate. An antidiarrheal agent (loperamide [Imodium]) is sometimes used to slow intestinal transit.

Kegel exercises (see Table 46-19) are used to strengthen and coordinate the pelvic floor muscles to improve continence. Biofeedback therapy may be recommended to improve awareness of rectal sensation, coordinate internal and external anal sphincters, and increase the strength of external sphincter contraction. Biofeedback training requires intact sensory and motor nerves and motivation to learn. It is a safe, painless, and relatively inexpensive treatment for fecal incontinence.[8]

An injectable treatment, dextranomer/hyaluronic acid gel (Solesta), is reserved for patients who have failed conservative fecal incontinence management. In this treatment, 4 mL of the gel is injected into the deep submucosa of the patient's anal canal. It acts through narrowing of the anal canal. No anesthesia is required. Postinjection pain and bleeding may occur.

Surgery (e.g., sphincter repair procedures) is considered only when nonsurgical conservative treatment fails, the patient has a full-thickness prolapse, and the sphincter needs repair. A colostomy is sometimes necessary.

NURSING MANAGEMENT FECAL INCONTINENCE

NURSING ASSESSMENT

Fecal incontinence is embarrassing, uncomfortable, and irritating to the skin.[9] Its unpredictable nature makes it difficult to maintain school and work activities and hampers social or intimate contact. Be sensitive to the patient's feelings when discussing incontinence. When the underlying cause cannot be corrected, help the patient reestablish a predictable pattern of defecation. Ask about bowel patterns before the incontinence developed; current bowel habits; stool consistency and frequency; and symptoms, including pain during defecation and a feeling of incomplete evacuation *(tenesmus)*. Assess whether the patient has defecation urgency and sensation of passing flatus and leaking stool. Check the perineal area for irritation or breakdown. Ask about daily activities (mealtimes and work), diet, and family and social activities. The Bristol Stool Scale is helpful for assessing stool consistency *(www.poopreport.com/Poll/bristol_scale.html)*.

Patients who are critically ill and have fecal incontinence are at risk for *incontinence-associated dermatitis* (IAD).[9] IAD is characterized by erythema and skin denudement (erosion) of the perianal or genital areas, buttocks, or upper thighs. It is caused by chemical irritants in feces. Dark-skinned patients may have areas of hypopigmentation. These skin changes place the patient at risk for fungal infection.

NURSING DIAGNOSES

Nursing diagnoses for the patient with fecal incontinence include, but are not limited to, the following:
- Bowel incontinence *related to* inability to control bowel function
- Self-care deficit (toileting) *related to* inability to manage bowel evacuation voluntarily
- Risk for situational low self-esteem *related to* inability to control bowel movements
- Risk for impaired skin integrity *related to* incontinence of stool

PLANNING

The overall goals are that the patient with fecal incontinence will (1) have predictable bowel elimination, (2) maintain perianal skin integrity, (3) participate in work and social activities, and (4) avoid self-esteem problems related to bowel control.

NURSING IMPLEMENTATION

Regardless of the cause of fecal incontinence, bowel training is an effective strategy for many patients. Bowel elimination occurs at regular intervals in most people. Knowing the patient's usual bowel pattern can assist you in planning a bowel program that will achieve optimal stool consistency and predictable bowel elimination patterns. For the hospitalized patient, placement on a bedpan, assistance to a bedside commode, or walks to the bathroom at a regular time daily help to establish regular defecation.[10] For many persons, a good time to schedule elimination is within 30 minutes after breakfast.

If these techniques are ineffective in reestablishing bowel regularity, a bisacodyl (Dulcolax) glycerin suppository or a small phosphate enema may be administered 15 to 30 minutes before the usual evacuation time. These preparations stimulate the anorectal reflex. Since stimulation will not occur unless the suppository or enema touches the rectal wall, first check for stool in the rectum and digitally remove it before inserting the laxative. Once a regular pattern is established, these drugs are discontinued. Digital stimulation is another method for stimulating the anorectal reflex and is commonly included in bowel programs for people with neurogenic bowels (e.g., from spinal cord injury). Irrigation of the rectum and colon (usually with tap water) at regular intervals is another method to achieve continence in patients with neurogenic bowel.[11]

Maintenance of perianal skin integrity is of utmost importance, especially in the bedridden and older adult patient. Incontinence can contaminate wounds, damage the skin, cause bladder infections, and spread infection such as *C. difficile*. Containment of the feces is essential, but it is difficult to maintain a seal with pouching systems and incontinence pads. Avoid the use of rectal tubes and urinary catheters because they can decrease responsiveness of the rectal sphincter and cause ulceration of the rectal mucosa. Fecal management systems such as the Zassi Bowel Management System, Flexi-Seal, and ActiFlo indwelling bowel catheter are designed to contain loose and liquid stools of bedridden patients without damaging the rectum or anal sphincters.[12]

Incontinence briefs may help maintain skin integrity if changed frequently. Implementation of a defined skin care program can reduce IAD. This includes prompt cleansing, moisturizing, and skin protection. The skin is cleaned with a mild soap and rinsed to remove feces, the area is dried, and a protective skin barrier cream is applied. For patients unable to care for themselves at home, teach the caregiver practices to maintain skin integrity.

Teach patients with fecal incontinence to avoid foods such as caffeine that worsen symptoms. In addition, exercising after meals can aggravate symptoms of incontinence.

CONSTIPATION

Normal bowel movements are formed and easy to pass. Frequency varies from three bowel movements daily to one bowel movement every 3 days. **Constipation** is characterized by absent or infrequent stools and hard, dry stools that are difficult to defecate. Because individuals vary, it is important to compare the current symptoms with the patient's normal pattern of elimination.

Etiology and Pathophysiology

Common causes of constipation include taking in insufficient dietary fiber or fluids, decreasing physical activity, and ignoring the defecation urge. Many drugs, especially opioids, cause constipation.[13] Constipation occurs with diseases that slow GI transit and hamper neurologic function such as diabetes mellitus, Parkinson's disease, and multiple sclerosis. Emotions, including anxiety, depression, and stress, affect the GI tract and can contribute to constipation.[14] Causes of constipation are summarized in eTable 43-2 (available on the website for this chapter).

Some people believe that they are constipated if they do not have a daily bowel movement. This can result in chronic laxative use and subsequent *cathartic colon syndrome,* a condition in which the colon becomes dilated and atonic (lacking muscle tone). Ultimately, the person cannot defecate without a laxative.

Ignoring the urge to defecate for a prolonged period can cause the muscles and mucosa of the rectum to become insensitive to the presence of feces. In addition, the prolonged retention of feces results in drying of stool due to water absorption. The harder and drier the feces, the more difficult it is to expel.

Clinical Manifestations

The clinical presentation of constipation may vary from a chronic discomfort to an acute event mimicking an "acute abdomen." Stools are absent or hard, dry, and difficult to pass. Abdominal distention, bloating, increased flatulence, and increased rectal pressure may also be present.

Hemorrhoids are the most common complication of chronic constipation. They result from venous engorgement caused by repeated *Valsalva maneuvers* (straining) and venous compression from hard impacted stool. Valsalva maneuver may have serious outcomes for patients with heart failure, cerebral edema, hypertension, and coronary artery disease. During straining, the patient inspires deeply and holds the breath while contracting abdominal muscles and bearing down. This increases both intraabdominal and intrathoracic pressures and reduces venous return to the heart. The heart rate decreases (bradycardia) temporarily, the cardiac output decreases, and a transient drop in arterial pressure occurs. When the patient relaxes, thoracic pressure falls, resulting in a sudden flow of blood into the heart, increased heart rate (tachycardia), and an immediate rise in arterial pressure. These changes may be fatal for the patient who cannot compensate for the sudden increased blood flow returning to the heart.

In the presence of *obstipation* (severe constipation when no gas or stool is expelled) or fecal impaction secondary to constipation, colonic perforation may occur. Perforation, which is life threatening, causes abdominal pain, nausea, vomiting, fever, and an elevated WBC count. Rectal mucosal ulcers and fissures may also occur as a result of stool stasis or straining. Diverticulosis is another potential complication of chronic constipation and is described later in this chapter. These complications are most common in older patients.

Diagnostic Studies and Collaborative Care

Perform a thorough history and physical examination so that the underlying cause of constipation can be identified and

TABLE 43-5 DRUG THERAPY

Constipation

Mechanism of Action	Example	Comments
Bulk Forming		
Absorbs water; increases bulk, thereby stimulating peristalsis *Action:* Usually within 24 hr	methylcellulose (Citrucel) psyllium (Metamucil, Perdiem, Konsyl, Hydrocil, Fiberall)	Contraindicated in patients with abdominal pain, nausea, and vomiting and in patients suspected of having appendicitis, biliary tract obstruction, or acute hepatitis. Must be taken with fluids (≥8 oz); best choice for initial treatment of constipation.
Stool Softeners and Lubricants		
Lubricate intestinal tract and soften feces, making hard stools easier to pass; do not affect peristalsis *Action:* Softeners in 72 hr, lubricants in 8 hr	*Softeners:* docusate (Colace, Surfak, Peri-Colace) *Lubricants:* mineral oil (Fleet's Oil Retention Enema, Kondremul Plain)	Can block absorption of fat-soluble vitamins such as vitamin K, which may increase risk of bleeding in patients on anticoagulants.
Saline and Osmotic Solutions		
Cause retention of fluid in intestinal lumen caused by osmotic effect *Action:* Within 15 min–3 hr	Magnesium salts (magnesium citrate, Milk of Magnesia) Sodium phosphates (Fleet Enema, Phospho-soda) lactulose (Constulose) polyethylene glycol (MiraLAX, GoLYTELY, CoLyte)	Magnesium-containing products may cause hypermagnesemia in patients with renal insufficiency.
Stimulants		
Increase peristalsis by irritating colon wall and stimulating enteric nerves *Action:* Usually within 12 hr	cascara sagrada, senna (Senokot) phenolphthalein: sennosides (Ex-Lax), bisacodyl (Correctol, Feen-a-Mint, Dulcolax), docusate/phenolphthalein (Doxidan)	Cause melanosis coli (brown or black pigmentation of colon). Are most widely abused laxatives. Should not be used in patients with impaction or obstipation.
Selective Chloride Channel Activator		
Increases intestinal fluid secretion and motility *Action:* Usually within 24 hr	lubiprostone (Amitiza)	Used in the treatment of idiopathic constipation and irritable bowel syndrome with constipation (women only). Contraindicated in patients with history of mechanical GI obstruction.
Intestinal Secretagogue		
Increases fluid secretion and accelerates intestinal transit. *Action:* Usually within 24 hr	linaclotide (Linzess)	Used in the treatment of idiopathic constipation and irritable bowel syndrome with constipation (men and women).

treatment started. Ask the patient about usual defecation patterns and habits, diet, exercise, use of laxatives, and conditions such as obstetric injuries that could contribute to difficulties with defecation. Abdominal x-rays, barium enema, colonoscopy, sigmoidoscopy, and anorectal manometry may be performed. Many cases of constipation can be prevented by increasing dietary fiber, fluid intake, and exercise. Laxatives (Table 43-5) and enemas may be used to treat acute constipation, but are used cautiously because overuse leads to chronic constipation.[15]

The choice of laxative or enema depends on the severity of the constipation and the patient's health. Daily bulk-forming preparations are used to prevent constipation because they work like dietary fiber and do not cause dependence. Stool softeners are also used to prevent constipation. Bisacodyl tablets and suppositories, milk of magnesia, and lactulose act more rapidly. They are also more likely to cause dependence. Methylnaltrexone (Relistor) is a peripheral μ-opiate receptor antagonist that decreases constipation caused by opioid use. The drug is administered subcutaneously. This agent does not block the analgesic effects.[16]

Enemas are fast acting and beneficial for immediate treatment of constipation, but must be used cautiously. Soapsuds enemas produce inflammation of colon mucosa, tap water enemas can potentially lead to water intoxication, and sodium phosphate (e.g., Fleet) enemas may cause electrolyte imbalances in patients with cardiac and renal problems.

Biofeedback therapy may benefit patients who are constipated as a result of *anismus* (uncoordinated contraction of the anal sphincter during straining). For the patient whose perceived constipation is related to rigid beliefs regarding bowel function, initiate a discussion about these concerns. Give appropriate information on normal bowel function and discuss the adverse consequences of excessive use of laxatives and enemas.

A patient with severe constipation related to bowel motility or mechanical disorders may require more intensive treatment. Diagnostic studies include anorectal manometry, GI tract transit studies, and sigmoidoscopic rectal biopsies. In a patient with unrelenting constipation, a subtotal colectomy with ileorectal anastomosis may be performed.

Nutritional Therapy. Diet is an important factor in the prevention of constipation. Many patients experience improved symptoms when they increase their intake of dietary fiber and fluids. Dietary fiber is found in fruits, vegetables, and grains (Table 43-6). Wheat bran and prunes are especially effective for preventing and treating constipation. Insoluble fiber is found in higher concentrations in whole wheat and bran.[17]

TABLE 43-6 NUTRITIONAL THERAPY

High-Fiber Foods

High-fiber foods are especially recommended for patients with diverticulosis, irritable bowel syndrome, constipation, hemorrhoids, atherosclerosis, hyperlipidemia, and diabetes mellitus.

	Fiber/ Serving (g)	Serving Size	Calories/ Serving
Vegetables			
Asparagus	3.5	½ cup	18
Beans			
• Navy	8.4	½ cup	80
• Kidney	9.7	½ cup	94
• Lima	8.3	½ cup	63
• Pinto	8.9	½ cup	78
• String	2.1	½ cup	18
Broccoli	3.5	½ cup	18
Carrots, raw	1.8	½ cup	15
Corn	2.6	½ medium ear	72
Peas, canned	6.7	½ cup	63
Potatoes			
• Baked	1.9	½ medium	72
• Sweet	2.1	½ medium	79
Squash, acorn	7.0	1 cup	82
Tomato, raw	1.5	1 small	18
Fruits			
Apple	2.0	½ large	42
Blackberries	6.7	¾ cup	40
Orange	1.6	1 small	35
Peach	2.3	1 medium	38
Pear	2.0	½ medium	44
Raspberries	9.2	1 cup	42
Strawberries	3.1	1 cup	45
Grain Products			
Bread, whole wheat	1.3	1 slice	59
Cereal			
• All Bran (100%)	8.4	⅓ cup	70
• Corn Flakes	2.6	¾ cup	70
• Shredded Wheat	2.8	1 biscuit	70
Popcorn	3.0	3 cups	62

Dietary fiber adds to the stool bulk directly and by attracting water. Therefore adequate fluid intake (2 L/day) is essential. Large, bulky stools move through the colon much more quickly than small stools. However, the recommended fluid intake may be contraindicated in the patient with cardiac disease or renal insufficiency or failure. Inform the patient that increasing fiber intake may initially increase gas production because of fermentation in the colon, but this effect decreases with use.

NURSING MANAGEMENT CONSTIPATION

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with constipation are presented in Table 43-7.

NURSING DIAGNOSIS

Nursing diagnoses for the patient with constipation include, but are not limited to, the following:

- Constipation *related to* inadequate intake of dietary fiber and fluid and decreased physical activity

TABLE 43-7 NURSING ASSESSMENT

Constipation

Subjective Data

Important Health Information

Past health history: Colorectal disease, neurologic dysfunction, bowel obstruction, environmental changes, cancer, irritable bowel syndrome, diabetes mellitus

Medications: Aluminum and calcium antacids, anticholinergics, antidepressants, antihistamines, antipsychotics, diuretics, opioids, iron, laxatives, enemas

Functional Health Patterns

Health perception–health management: Chronic laxative or enema abuse; rigid beliefs regarding bowel function; malaise

Nutritional-metabolic: Changes in diet or mealtime; inadequate fiber and fluid intake; anorexia, nausea

Elimination: Change in usual elimination patterns; hard, difficult-to-pass stool, decrease in frequency and amount of stools; flatus, abdominal distention; tenesmus, rectal pressure; fecal incontinence (if impacted)

Activity-exercise: Change in daily activity routines; immobility; sedentary lifestyle

Cognitive-perceptual: Dizziness, headache, anorectal pain; abdominal pain on defecation

Coping–stress tolerance: Acute or chronic stress

Objective Data

General

Lethargy

Integumentary

Anorectal fissures, hemorrhoids, abscesses

Gastrointestinal

Abdominal distention; hypoactive or absent bowel sounds; palpable abdominal mass; fecal impaction; small, hard, dry stool; stool with blood

Possible Diagnostic Findings

Guaiac-positive stools; abdominal x-ray demonstrating stool in lower colon

PLANNING

The overall goals are that the patient with constipation will (1) increase dietary intake of fiber and fluids; (2) increase physical activity; (3) pass soft, formed stools; and (4) not have any complications, such as bleeding hemorrhoids.

NURSING IMPLEMENTATION

Nursing management should be based on the patient's symptoms and assessment (see Table 43-7). Teach the patient about the importance of diet in the prevention of constipation. A patient and caregiver teaching guide for constipation is presented in Table 43-8. Emphasize using a high-fiber diet, increasing fluid intake, and exercising regularly. Teach the patient to establish a regular time to defecate and not to suppress the urge to defecate. Discourage the use of laxatives and enemas to achieve fecal elimination.

Defecation is easiest when the person is sitting on a commode with the knees higher than the hips. The sitting position allows gravity to aid defecation, and flexing the hips straightens the angle between the anal canal and the rectum so that stool flows out more easily. Place a footstool in front of the toilet to promote flexion of the thighs. It is challenging to defecate while sitting on a bedpan. For a patient in bed, elevate the head of the bed as high as the patient can tolerate.

TABLE 43-8 PATIENT & CAREGIVER TEACHING GUIDE

Constipation

Include the following instructions when teaching the patient and caregiver about management of constipation.

1. Eat Dietary Fiber

Eat 20-30 g of fiber per day. Gradually increase the amount of fiber eaten over 1-2 wk. Fiber softens hard stool and adds bulk to stool, promoting evacuation.

- Foods high in fiber: raw vegetables and fruits, beans, breakfast cereals (All Bran, oatmeal)
- Fiber supplements: Metamucil, Citrucel, FiberCon

Eat prunes or drink prune juice daily. Prunes stimulate defecation.

2. Drink Fluids

Drink 3 quarts per day. Drink water or fruit juices. Avoid caffeinated coffee, tea, and cola. Fluid softens hard stools. Caffeine stimulates fluid loss through urination.

3. Exercise Regularly

Walk, swim, or bike at least three times per wk. Contract and relax abdominal muscles when standing or by doing sit-ups to strengthen muscles and prevent straining. Exercise stimulates bowel motility and moves stool through the colon.

4. Establish a Regular Time to Defecate

First thing in the morning or after the first meal of the day is a good time because people often have the urge to defecate at this time.

5. Do Not Delay Defecation

Respond to the urge to have a bowel movement as soon as possible. Delaying defecation results in hard stools and a decreased "urge" to defecate. Water is absorbed from stool by the intestine over time. The colon becomes less sensitive to the presence of stool in the rectum.

6. Record Your Bowel Elimination Pattern

Develop a habit of recording when you have a bowel movement on your calendar. Regular monitoring of bowel movement will assist in early identification of a problem.

7. Avoid Laxatives and Enemas

Do not overuse laxatives and enemas because they cause dependence. People who overuse them are unable to have a bowel movement without them.

Most people are embarrassed by the sights and sounds of defecation, so provide as much privacy as possible. Encourage patients to exercise abdominal muscles and to contract abdominal muscles several times a day. Sit-ups and straight-leg raises can also help improve abdominal muscle tone.

Teach patients taking bulking products to follow product recommendations in terms of fluid intake. Patients may initially experience an increase in flatus that will decrease with use.

ACUTE ABDOMINAL PAIN

Etiology and Pathophysiology

Acute abdominal pain is pain of recent onset. It may signal a life-threatening problem and therefore requires immediate attention.[18] Causes include damage to organs in the abdomen and pelvis, which leads to inflammation, infection, obstruction, bleeding, and perforation (Fig. 43-1). The most common causes of acute abdominal pain are listed in Table 43-9. Perforation of the GI tract also results in irritation of the *peritoneum* (serous membrane lining the abdominal cavity) and peritonitis. Hypovolemic shock occurs from bleeding or when obstruction and peritonitis cause large amounts of fluid to move from the vascular space into the abdomen (third spacing).

TABLE 43-9 CAUSES OF ACUTE ABDOMINAL PAIN

- Abdominal compartment syndrome
- Acute pancreatitis
- Appendicitis
- Bowel obstruction
- Cholecystitis
- Diverticulitis
- Gastroenteritis
- Pelvic inflammatory disease
- Perforated gastric or duodenal ulcer
- Peritonitis
- Ruptured abdominal aneurysm
- Ruptured ectopic pregnancy

Clinical Manifestations

Pain is the most common symptom of an acute abdominal problem. The patient may also complain of nausea, vomiting, diarrhea, constipation, flatulence, fatigue, fever, and bloating.

Diagnostic Studies and Collaborative Care

Diagnosis begins with a complete history and physical examination. Description of the pain (frequency, timing, duration, location), accompanying symptoms, and sequence of symptoms (e.g., pain before or after vomiting) provide vital clues about the origin of the problem. Note the patient's position. The fetal posture is common with peritoneal irritation (e.g., appendicitis), a supine posture with outstretched legs is seen with visceral pain, and restlessness and a seated posture commonly occur with bowel obstructions and obstructions from kidney stones and gallstones.

Physical examination includes examination of the abdomen, rectum, and pelvis. A complete blood count (CBC), urinalysis, abdominal x-ray, and electrocardiogram are done, along with an ultrasound or CT scan. A pregnancy test is performed in women of childbearing age with acute abdominal pain to rule out ectopic pregnancy (see Table 43-9).

Emergency management of the patient with acute abdominal pain is presented in Table 43-10. The goal of management is to identify and treat the cause, and monitor and treat complications, especially shock. Careful use of pain medications (e.g., morphine) provides pain relief without interfering with diagnostic accuracy when patients have nontraumatic acute abdominal pain.

An immediate surgical consult is needed. The surgeon may perform a diagnostic laparoscopy to inspect the surface of abdominal organs, obtain biopsy specimens, perform laparoscopic ultrasounds, and remove organs. A laparotomy is used when laparoscopic techniques are inadequate. If the cause of the acute abdomen can be surgically removed (e.g., inflamed appendix) or surgically repaired (e.g., ruptured abdominal aneurysm), surgery is considered definitive therapy.

NURSING MANAGEMENT ACUTE ABDOMINAL PAIN

NURSING ASSESSMENT

For the patient complaining of acute abdominal pain, take vital signs immediately and again at frequent intervals. Increased pulse and decreasing blood pressure indicate impending shock. An elevated temperature suggests an inflammatory or infectious process. Intake and output measurement provides essential information about the adequacy of vascular volume. Altered

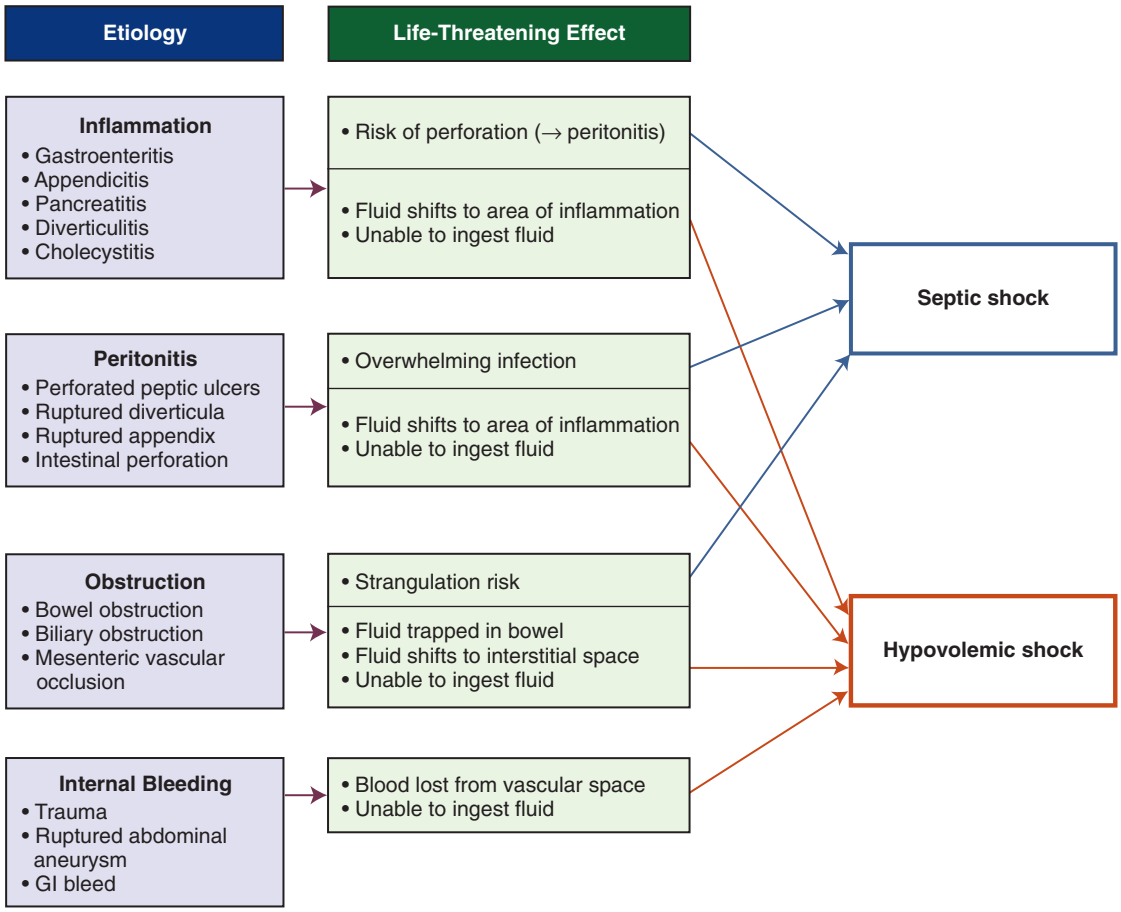

FIG. 43-1 Etiology of acute abdominal pain and pathophysiologic sequelae.

mental status indicates poor cerebral perfusion. Skin color and temperature and peripheral pulse strength provide information about skin perfusion. Inspect the abdomen for distention, masses, abnormal pulsation, symmetry, hernias, rashes, scars, and pigmentation changes. Auscultate bowel sounds. Bowel sounds that are diminished or absent in a quadrant may indicate a bowel obstruction, acute peritonitis, or paralytic ileus. Palpation should be gentle. Determine pain from peritoneal irritation by asking the person to cough, palpating the abdomen gently, or gently shaking the bed.

Ask the patient about the onset, location, intensity, duration, frequency, and character of pain. Note whether the pain has spread or moved to new sites (quadrants) and what makes the pain worse or better. Is the pain associated with other symptoms, such as nausea, vomiting, changes in bowel and bladder habits, or vaginal discharge in women? Assessment of vomiting includes the amount, color, consistency, and odor of the emesis. Also ask about usual and changes in bowel patterns and habits.

NURSING DIAGNOSES

Nursing diagnoses for the patient with acute abdominal pain include, but are not limited to, the following:

- Acute pain *related to* inflammation of the peritoneum and abdominal distention
- Risk for deficient fluid volume *related to* collection of fluid in peritoneal cavity secondary to inflammation or infection
- Anxiety *related to* pain and uncertainty of cause or outcome of condition

PLANNING

The overall goals are that the patient with acute abdominal pain will have (1) relief of abdominal pain, (2) resolution of inflammation, (3) freedom from complications (especially hypovolemic shock), and (4) normal nutritional status.

NURSING IMPLEMENTATION

General care for the patient with acute abdominal pain involves management of fluid and electrolyte imbalances, pain, and anxiety. Assess the quality and intensity of pain at regular intervals, and provide medication and other comfort measures. Maintain a calm environment and provide information to help allay anxiety. A nasogastric (NG) tube may be used to decrease vomiting and relieve discomfort from gastric distention. Conduct ongoing assessments of vital signs, intake and output, and level of consciousness, which are key indicators of hypovolemic shock.

ACUTE INTERVENTION

Preoperative Care. Preoperative care includes the emergency care of the patient described in Table 43-10 and general care of the preoperative patient (see Chapter 18).

Postoperative Care. Postoperative care depends on the type of surgical procedure performed. In some cases a laparotomy is necessary. When appropriate, a laparoscopic approach is used. Laparoscopic procedures result in lower rates of postoperative complications (poor wound healing and paralytic ileus), earlier diet advancement, and shorter hospital stays compared with open surgical procedures. eNursing Care Plan 20-1, a general plan for the postoperative patient, is presented on the website for Chapter 20.

TABLE 43-10 EMERGENCY MANAGEMENT

Acute Abdominal Pain

Etiology	Assessment Findings	Interventions
Inflammation • Appendicitis • Cholecystitis • Crohn's disease • Gastritis • Pancreatitis • Pyelonephritis • Ulcerative colitis **Vascular Problems** • Ruptured aortic aneurysm • Mesenteric vascular occlusion **Gynecologic Problems** • Pelvic inflammatory disease • Ruptured ectopic pregnancy • Ruptured ovarian cyst **Infectious Disease** • *Escherichia coli* O157:H7 • *Giardia* • *Salmonella* **Other** • Obstruction or perforation of abdominal organ • Gastrointestinal bleeding or ischemia • Trauma	**Abdominal and Gastrointestinal Findings** • Diffuse, localized, dull, burning, or sharp abdominal pain or tenderness • Rebound tenderness • Abdominal distention • Abdominal rigidity • Nausea and vomiting • Diarrhea • Hematemesis • Melena **Hypovolemic Shock** • ↓ Blood pressure • ↓ Pulse pressure • Tachycardia • Cool, clammy skin • ↓ Level of consciousness • ↓ Urine output (<0.5 mL/kg/hr)	**Initial** • Ensure patent airway. • Administer O_2 via nasal cannula or non-rebreather mask. • Establish IV access with large-bore catheter and infuse warm normal saline or lactated Ringer's solution. Insert additional large-bore catheter if shock present. • Obtain blood for CBC and electrolyte levels. • Anticipate order for amylase level, pregnancy tests, clotting studies, and type and crossmatch as appropriate. • Insert indwelling urinary catheter. • Obtain urinalysis. • Insert NG tube as needed. **Ongoing Monitoring** • Monitor vital signs, level of consciousness, O_2 saturation, and intake/output. • Assess quality and amount of pain. • Assess amount and character of emesis. • Anticipate surgical intervention. • Keep patient NPO.

Postoperatively an NG tube with low suction may be used in selected patients to empty the stomach and prevent gastric dilation. If the upper GI tract has been entered, drainage from the NG tube may be dark brown to dark red for the first 12 hours. Later it should be light yellowish brown, or it may have a greenish tinge because of bile. If a dark red color continues or if bright red blood is observed, notify the surgeon because of the possibility of hemorrhage. "Coffee-ground" granules in the drainage indicate blood that has been modified by acidic gastric secretions.

Nausea and vomiting are common after a laparotomy and may be caused by the surgery, decreased peristalsis, or pain medications. Antiemetics such as ondansetron (Zofran), trimethobenzamide (Tigan), and prochlorperazine (Compazine) may be ordered. Management of nausea and vomiting is discussed in Chapter 42. Monitor fluid and electrolyte status along with blood pressure, heart rate, and respirations.

Swallowed air and reduced peristalsis from decreased mobility, manipulation of the abdominal organs during surgery, and anesthesia can result in abdominal distention and gas pains. Early ambulation helps restore peristalsis and eliminate flatus and gas pain. Gradually, as intestinal activity increases, distention and gas pain disappear.

AMBULATORY AND HOME CARE. Preparation for discharge begins soon after surgery. Teach the patient and caregiver about any modifications in activity, care of the incision, diet, and drug therapy. Clear liquids are given initially after surgery and, if tolerated, the patient progresses to a regular diet.

Early ambulation speeds recovery, but normal activities are resumed gradually, with planned rest periods. After surgery the patient is generally instructed not to lift anything heavier than a few pounds. The patient and caregiver should be aware of possible complications after surgery. Teach them to notify the surgeon immediately if fever, vomiting, pain, weight loss, incisional drainage, or changes in bowel function occur.

EVALUATION

The expected outcomes are that the patient with acute abdominal pain will have

- Resolution of the cause of the acute abdominal pain
- Relief of abdominal pain and discomfort
- Freedom from complications (especially hypovolemic shock and septicemia)
- Normal fluid, electrolyte, and nutritional status

CHRONIC ABDOMINAL PAIN

Chronic abdominal pain may originate from abdominal structures or may be referred from a site with the same or a similar nerve supply. The pain is often described as dull, aching, or diffuse. Common causes of chronic abdominal pain include irritable bowel syndrome (IBS), peptic ulcer disease, chronic pancreatitis, hepatitis, pelvic inflammatory disease, and vascular insufficiency. (Some of these disorders are discussed in this chapter).

Diagnosis of the cause of chronic abdominal pain begins with a thorough history and description of specific pain characteristics, including severity, location, frequency, duration, and onset. The assessment also includes factors that increase or decrease the pain, such as meals, defecation, and activities.

GENDER DIFFERENCES

Irritable Bowel Syndrome (IBS)

Men
- Report manifestations of diarrhea more commonly than women
- Less likely to admit to symptoms or seek help for them than women

Women
- Affects women 2 to 2.5 times more often than men
- Report manifestations of constipation more commonly than men
- Report more extraintestinal co-morbidities (e.g., migraine headache, insomnia, fibromyalgia) than men
- Alosetron (Lotronex) (antidiarrheal) approved only for women with severe IBS diarrhea

Endoscopy, CT scan, magnetic resonance imaging (MRI), laparoscopy, and barium studies may be done. Treatment for chronic abdominal pain depends on the underlying cause.

IRRITABLE BOWEL SYNDROME

Irritable bowel syndrome (IBS) is a common, chronic functional disorder, meaning that no organic cause is currently known.[19] Symptoms of IBS, including abdominal pain or discomfort and alterations in bowel patterns, are intermittent and may occur for years. Patients often report a history of GI infections and food intolerances. However, the role of food allergies in IBS is unclear. Other dietary factors that may contribute to symptoms include fermentable oligo-, di-, and monosaccharides and polyols (FODMAPs).[20] Examples include fructans (found in wheat), galactans, lactose, fructose, sorbitol, and xylitol.

Psychologic stressors (e.g., depression, anxiety, sexual abuse, posttraumatic stress disorder) are associated with development and exacerbation of IBS.[19] IBS is more frequently diagnosed in women than in men. In addition to abdominal pain and diarrhea or constipation, patients commonly experience abdominal distention, excessive flatulence, bloating, urgency, and sensation of incomplete evacuation. Non-GI symptoms may include fatigue and sleep disturbances.

There are no specific physical findings with IBS. The key to accurate diagnosis is a thorough history and physical examination. Ask patients to describe symptoms, past health history (including psychosocial factors such as stress and anxiety), family history, and drug and diet history. Determine if and how IBS symptoms interfere with school, work, or recreational activities. Diagnostic tests are selectively used to rule out other disorders such as colorectal cancer, IBD, endometriosis, and malabsorption disorders (lactose intolerance, celiac disease). Symptom-based criteria for IBS have been standardized and are referred to as the Rome criteria III (see eTable 43-3 on the website for this chapter).

Treatment is directed at psychologic and dietary factors and drugs to regulate stool output. Patients are more likely to improve with treatment if they have a trusting relationship with their health care provider. Encourage the patient to verbalize concerns. Since treatment is often focused on symptoms, patients may benefit from keeping a diary of symptoms, diet, and episodes of stress to help identify factors that seem to trigger the IBS symptoms. If tolerated, encourage the patient to have a dietary fiber intake of at least 20 g/day (see Table 43-6) or to use a stool bulking agent. Increases in dietary fiber should be started gradually to avoid bloating and abdominal discomfort from gas.

Advise the patient whose primary symptoms are abdominal distention and flatulence to avoid common gas-producing foods such as broccoli and cabbage. Yogurt may be better tolerated than milk products. Probiotics may be used because alterations in intestinal bacteria are believed to exacerbate the condition.[19]

Loperamide, a synthetic opioid that slows intestinal transit, may be used to treat diarrhea when it occurs. Alosetron (Lotronex), a serotonergic antagonist, is used for IBS patients with severe symptoms of pain and diarrhea. Because of serious side effects (e.g., severe constipation, ischemic colitis), alosetron is available only in a restricted access program for women who have not responded to other IBS therapies. Lubiprostone (Amitiza) is approved for the treatment of IBS with constipation in women. Linaclotide (Linzess) is approved for the treatment of IBS with constipation in men and women.

DRUG ALERT: Alosetron (Lotronex)
- Patients may experience severe constipation and ischemic colitis (reduced blood flow to intestines).
- If constipation occurs, drug should be discontinued.
- Symptoms of ischemic colitis include abdominal pain and blood in stool.

Psychologic therapies include cognitive-behavioral therapy, stress management techniques, acupuncture, and hypnosis. Low doses of tricyclic antidepressants seem beneficial, possibly because they decrease peripheral nerve sensitivity. No single therapy has been found to be effective for all patients with IBS.

ABDOMINAL TRAUMA

Etiology and Pathophysiology

Injuries to the abdominal area usually are a result of blunt trauma or penetrating injuries. Common injuries of the abdomen include lacerated liver, ruptured spleen, mesenteric artery tears, diaphragm rupture, urinary bladder rupture, great vessel tears, renal or pancreas injury, and stomach or intestine rupture. *Blunt trauma* commonly occurs with motor vehicle accidents, beatings, and falls and may not be obvious because it does not leave an open wound. Both compression injuries (e.g., direct blow to the abdomen) and shearing injuries (e.g., rapid deceleration in a motor vehicle crash allowing some tissue to move forward while other tissues are held stationary) occur with blunt trauma. *Penetrating injuries* occur when a gunshot or stabbing produces an obvious, open wound into the abdomen.[21]

When solid organs (liver, spleen) are injured, bleeding can be profuse, resulting in hypovolemic shock. When contents from hollow organs (e.g., bladder, stomach, intestines) spill into the peritoneal cavity, the patient is at risk for peritonitis. In addition, abdominal compartment syndrome can develop.

Abdominal compartment syndrome is excessively high pressure in the abdomen (abdominal hypertension). Anything that increases the volume in the abdominal cavity—including edematous organs, bleeding, and third spacing caused by obstruction and inflammation—increases abdominal pressure.[22] High abdominal pressure restricts ventilation, potentially leading to respiratory failure. The high pressure also decreases cardiac output, venous return, and arterial perfusion of organs. Decreased perfusion to the kidneys can lead to renal failure.

Clinical Manifestations

Careful assessment provides important clues to the type and severity of injury. Intraabdominal injuries are often associated with low rib fractures, fractured femur, fractured pelvis, and

TABLE 43-11 EMERGENCY MANAGEMENT

Abdominal Trauma

Etiology	Assessment Findings	Interventions
Blunt • Falls • Motor vehicle collisions • Pedestrian event • Assault with blunt object • Crush injuries • Explosions **Penetrating** • Knife • Gunshot wounds • Other missiles	**Hypovolemic Shock** • ↓ Level of consciousness • Tachypnea • Tachycardia • ↓ Blood pressure • ↓ Pulse pressure **Surface Findings** • Abrasions or ecchymoses on abdominal wall, flank, or peritoneum • Open wounds: lacerations, eviscerations, puncture wounds, gunshot wounds • Impaled object • Healed incisions or old scars **Abdominal and Gastrointestinal Findings** • Nausea and vomiting • Hematemesis • Absent or decreased bowel sounds • Bloody urine (hematuria) • Abdominal distention • Abdominal rigidity • Abdominal pain with palpation • Rebound tenderness • Pain radiation to shoulder and back	**Initial** • Ensure patent airway. • Administer O_2 via non-rebreather mask. • Control external bleeding with direct pressure or sterile pressure dressing. • Establish IV access with two large-bore catheters and infuse warm normal saline or lactated Ringer's solution. • Obtain blood for type and crossmatch and CBC. • Remove clothing. • Stabilize impaled objects with bulky dressing—*do not remove.* • Cover protruding organs or tissue with sterile saline dressing. • Insert indwelling urinary catheter if there is no blood at the meatus, pelvic fracture, or boggy prostate. • Obtain urine for urinalysis. • Insert NG tube if no evidence of facial trauma. • Anticipate diagnostic peritoneal lavage. **Ongoing Monitoring** • Monitor vital signs, level of consciousness, O_2 saturation, and urine output. • Maintain patient warmth using blankets, warm IV fluids, or warm humidified O_2.

thoracic injury. If the patient was in an automobile accident, a contusion or abrasion across the lower abdomen may indicate internal organ trauma due to seat belt use. Seat belts can produce blunt trauma to abdominal organs by pressing the intestine and pancreas into the spinal column.

Clinical manifestations of abdominal trauma are (1) guarding and splinting of the abdominal wall (indicating peritonitis); (2) a hard, distended abdomen (indicating intraabdominal bleeding); (3) decreased or absent bowel sounds; (4) contusions, abrasions, or bruising over the abdomen; (5) abdominal pain; (6) pain over the scapula caused by irritation of the phrenic nerve by free blood in the abdomen; (7) hematemesis or hematuria; and (8) signs of hypovolemic shock (Table 43-11). Ecchymosis around the umbilicus (Cullen's sign) or flanks (Grey Turner's sign) may indicate retroperitoneal hemorrhage. Loss of bowel sounds occurs with peritonitis. If present, bowel sounds are heard in the chest when the diaphragm ruptures. Auscultation of bruits is indicative of arterial damage.

Diagnostic Studies

Laboratory tests include a baseline CBC and urinalysis. Even when bleeding, the patient will have normal hemoglobin and hematocrit because fluids are lost at the same rate as the red blood cells. Deficiencies are evident after fluid resuscitation begins. Blood in the urine may be a sign of damage to the kidney or bladder. Additional laboratory work includes arterial blood gases, prothrombin time, electrolytes, BUN and creatinine, and type and crossmatch (in anticipation of possible blood transfusions). An abdominal CT scan and focused abdominal sonography are the most common diagnostic methods, but the patient must be stable before going for CT. Diagnostic peritoneal lavage can be used to detect blood, bile, intestinal contents, and urine in the peritoneal cavity, but is generally used only for unstable patients to identify blood in the peritoneum.[22]

NURSING AND COLLABORATIVE MANAGEMENT ABDOMINAL TRAUMA

Emergency management of abdominal trauma focuses on establishing a patent airway and adequate breathing, fluid replacement, and prevention of hypovolemic shock (see Table 43-11). IV lines are inserted, and volume expanders or blood is given if the patient is hypotensive. An NG tube is inserted to decompress the stomach and prevent aspiration. Frequent ongoing assessment is necessary to monitor fluid status, detect deterioration in condition, and determine the necessity for surgery. An impaled object should never be removed until skilled care is available. Removal may cause further injury and bleeding. The decision about whether to do surgery depends on clinical findings, diagnostic test results, and the patient's response to conservative management.

INFLAMMATORY DISORDERS

APPENDICITIS

Appendicitis is inflammation of the appendix, a narrow blind tube that extends from the inferior part of the cecum (Fig. 43-2).

Etiology and Pathophysiology

In the United States, about 1 in 15 people will get appendicitis. It is most common in individuals 10 to 30 years of age. It is the most common cause of acute abdominal pain.[23] A common cause of appendicitis is obstruction of the lumen by a fecalith (accumulated feces) (see Fig. 43-2). Obstruction results in distention; venous engorgement; and the accumulation of mucus and bacteria, which can lead to gangrene, perforation, and peritonitis.

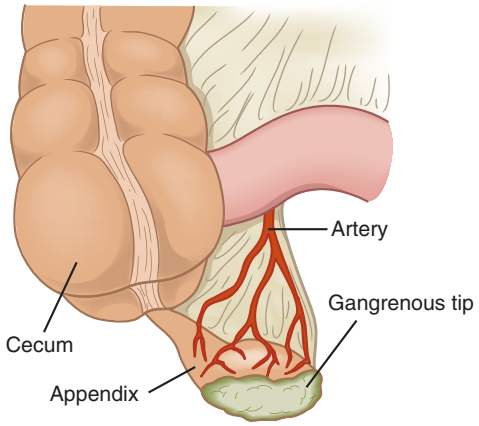

FIG. 43-2 In appendicitis the blood supply of the appendix is impaired by inflammation and bacterial infection in the wall of the appendix, which may result in gangrene.

Clinical Manifestations

Diagnosis can be difficult because many patients do not have classic symptoms. Typically appendicitis begins with periumbilical pain, followed by anorexia, nausea, and vomiting. The pain is persistent and continuous, eventually shifting to the right lower quadrant and localizing at McBurney's point (halfway between the umbilicus and the right iliac crest). Further assessment reveals localized tenderness, rebound tenderness, and muscle guarding. Coughing, sneezing, and deep inhalation magnify the pain. The patient usually prefers to lie still, often with the right leg flexed. Low-grade fever may or may not be present.[23] The older adult may report less severe pain, slight fever, and discomfort in the right iliac fossa.

Diagnostic Studies and Collaborative Care

Examination of the patient includes a complete history, physical examination, and a differential WBC count. The WBC count is mildly to moderately elevated in most cases. A urinalysis is done to rule out genitourinary conditions that mimic the manifestations of appendicitis. CT scan is the preferred diagnostic procedure, but ultrasound is also used.

If diagnosis and treatment are delayed, the appendix can rupture, and the resulting peritonitis can be fatal. The treatment of appendicitis is immediate surgical removal *(appendectomy)* if the inflammation is localized. Surgery, generally performed laparoscopically, is done as soon as the diagnosis is made. Antibiotics and fluid resuscitation are administered before surgery.

If the appendix has ruptured and there is evidence of peritonitis or an abscess, parenteral fluids and antibiotic therapy are given for 6 to 8 hours before the appendectomy to prevent dehydration and sepsis.

NURSING MANAGEMENT APPENDICITIS

Encourage the patient with abdominal pain to see a health care provider and to avoid self-treatment. Laxatives and enemas are especially dangerous because the resulting increased peristalsis may cause perforation of the appendix. To ensure that the stomach is empty in case surgery is needed, keep patients on nothing-by-mouth (NPO) status until they can be seen by a health care provider.

TABLE 43-12 CAUSES OF PERITONITIS

Primary	Secondary
• Blood-borne organisms • Genital tract organisms • Cirrhosis with ascites	• Appendicitis with rupture • Blunt or penetrating trauma to abdominal organs • Diverticulitis with rupture • Ischemic bowel disorders • Pancreatitis • Perforated intestine • Perforated peptic ulcer • Peritoneal dialysis • Postoperative (breakage of anastomosis)

Postoperative nursing management for the patient who has an appendectomy is similar to postoperative care of the patient after laparotomy. Ambulation begins the day of surgery or the first postoperative day. The diet is advanced as tolerated. The patient is usually discharged on the first or second postoperative day and resumes normal activities 2 to 3 weeks after surgery.

PERITONITIS

Etiology and Pathophysiology

Peritonitis results from a localized or generalized inflammatory process of the peritoneum. Causes of peritonitis are listed in Table 43-12. Primary peritonitis occurs when blood-borne organisms enter the peritoneal cavity. For example, the ascites that occurs with cirrhosis of the liver provides an excellent liquid environment for bacteria to flourish. Organisms can also enter the peritoneum during peritoneal dialysis. (Peritoneal dialysis is described in Chapter 47.)

Secondary peritonitis is much more common. It occurs when abdominal organs perforate or rupture and release their contents (bile, enzymes, and bacteria) into the peritoneal cavity. Common causes include a ruptured appendix, perforated gastric or duodenal ulcer, severely inflamed gallbladder, and trauma from gunshot or knife wounds.

Intestinal contents and bacteria irritate the normally sterile peritoneum and produce an initial chemical peritonitis, which is followed a few hours later by a bacterial peritonitis. The resulting inflammatory response leads to massive fluid shifts (peritoneal edema) and adhesions as the body attempts to wall off the infection.

Clinical Manifestations

Abdominal pain is the most common symptom of peritonitis. A universal sign of peritonitis is tenderness over the involved area. Rebound tenderness, muscular rigidity, and spasm are other signs of irritation of the peritoneum. Patients may lie still and take only shallow breaths because movement causes pain. Abdominal distention, fever, tachycardia, tachypnea, nausea, vomiting, and altered bowel habits may also be present. These manifestations vary depending on the severity and acuteness of the underlying condition. Complications of peritonitis include hypovolemic shock, sepsis, intraabdominal abscess formation, paralytic ileus, and acute respiratory distress syndrome. If treatment is delayed, peritonitis can be fatal.

Diagnostic Studies and Collaborative Care

A CBC is done to determine elevations in WBC count and hemoconcentration from fluid shifts (Table 43-13). Peritoneal

TABLE 43-13 COLLABORATIVE CARE

Peritonitis

Diagnostic
- History and physical examination
- CBC, including WBC differential
- Serum electrolytes
- Abdominal x-ray
- Abdominal paracentesis and culture of fluid
- CT scan or ultrasound
- Peritoneoscopy

Collaborative Therapy

Preoperative or Nonoperative
- NPO status
- IV fluid replacement
- Antibiotic therapy
- NG suction
- Analgesics (e.g., morphine)
- Oxygen PRN
- Preparation for surgery to include the above and parenteral nutrition

Postoperative
- NPO status
- NG tube to low-intermittent suction
- Semi-Fowler's position
- IV fluids with electrolyte replacement
- Parenteral nutrition as needed
- Antibiotic therapy
- Blood transfusions as needed
- Sedatives and opioids

aspiration may be performed and the fluid analyzed for blood, bile, pus, bacteria, fungus, and amylase content. An x-ray of the abdomen may show dilated loops of bowel consistent with paralytic ileus, free air if perforation has occurred, or air and fluid levels if an obstruction is present. Ultrasound and CT scans may be useful in identifying ascites and abscesses. Peritoneoscopy may be helpful in the patient without ascites. Direct examination of the peritoneum can be obtained along with biopsy specimens for diagnosis.

Patients with milder cases of peritonitis or those who are poor surgical risks may be managed medically. Treatment consists of antibiotics, NG suction, analgesics, and IV fluid administration. Surgery is indicated to locate the cause of the inflammation, drain purulent fluid, and repair any damage (e.g., perforated organs).

NURSING MANAGEMENT PERITONITIS

NURSING ASSESSMENT

Assessment of the patient's pain, including the location, is important and may help in determining the cause of peritonitis. Assess the patient for the presence and quality of bowel sounds, increasing abdominal distention, abdominal guarding, nausea, fever, and manifestations of hypovolemic shock.

NURSING DIAGNOSES

Nursing diagnoses for the patient with peritonitis include, but are not limited to, the following:
- Acute pain *related to* inflammation of the peritoneum and abdominal distention
- Risk for deficient fluid volume *related to* fluid shifts into the peritoneal cavity secondary to trauma, infection, or ischemia
- Anxiety *related to* uncertainty of cause or outcome of the condition and pain

PLANNING

The overall goals are that the patient with peritonitis will have (1) resolution of inflammation, (2) relief of abdominal pain, (3) freedom from complications (especially sepsis and hypovolemic shock), and (4) normal nutritional status.

NURSING IMPLEMENTATION

The patient with peritonitis is extremely ill and needs skilled supportive care. An IV line is inserted to replace vascular fluids lost to the peritoneal cavity and as an access for antibiotic therapy. Monitor the patient for pain and response to analgesics. The patient may be positioned with knees flexed to increase comfort. Sedatives may be given to allay anxiety.

Accurate monitoring of fluid intake and output and electrolyte status is necessary to determine replacement therapy. Monitor vital signs frequently. Antiemetics may be administered to decrease nausea and vomiting and prevent further fluid and electrolyte losses. The patient is placed on NPO status and may need an NG tube to decrease gastric distention and further leakage of bowel contents into the peritoneum. Low-flow oxygen therapy may be needed.

If the patient has an open surgical procedure, drains are inserted to remove purulent drainage and excess fluid. Postoperative care is similar to that for the patient with an exploratory laparotomy.

GASTROENTERITIS

Gastroenteritis is an inflammation of the mucosa of the stomach and small intestine. Acute gastroenteritis is defined as sudden diarrhea accompanied by nausea, vomiting, and abdominal cramping. Viruses are the most common cause of gastroenteritis. Other causes are presented in Table 43-1.

Norovirus is a leading cause of gastroenteritis from foodborne disease outbreaks in the United States. The Ridascreen Norovirus 3rd Generation EIA is used when a number of people have simultaneously contracted gastroenteritis and there is a clear avenue for virus transmission, such as a shared location or food.

Most cases of gastroenteritis are self-limiting. However, older adults and chronically ill patients may be unable to consume sufficient fluids orally to compensate for fluid loss. If dehydration occurs, IV fluid replacement may be necessary. As soon as tolerated, oral fluids containing glucose and electrolytes (e.g., Pedialyte) should be given. Nursing management of the patient with gastroenteritis is the same as for the patient with acute diarrhea (see pp. 963-964).

INFLAMMATORY BOWEL DISEASE

Inflammatory bowel disease (IBD) is a chronic inflammation of the GI tract. It is characterized by periods of remission interspersed with periods of exacerbation. The exact cause is unknown, and there is no cure. IBD is classified as either **Crohn's disease** or **ulcerative colitis** based on clinical manifestations (Table 43-14). As the name suggests, ulcerative colitis is

TABLE 43-14 COMPARISON OF ULCERATIVE COLITIS AND CROHN'S DISEASE

Characteristic	Ulcerative Colitis	Crohn's Disease
Clinical		
Usual age at onset	Teens to mid-30s*	Teens to mid-30s*
Diarrhea	Common	Common
Abdominal cramping pain	Common	Common
Fever (intermittent)	During acute attacks	Common
Weight loss	Rare	Common, may be severe
Rectal bleeding	Common	Infrequent
Tenesmus	Common	Rare
Malabsorption and nutritional deficiencies	Minimal incidence	Common
Pathologic		
Location	Usually starts in rectum and spreads in a continuous pattern up the colon	Occurs anywhere along GI tract in characteristic skip lesions. Most frequent site is terminal ileum
Distribution	Continuous areas of inflammation	Healthy tissue interspersed with areas of inflammation (skip lesions)
Depth of involvement	Mucosa and submucosa	Entire thickness of bowel wall (transmural)
Granulomas (noted on biopsy)	Occasional	Common
Cobblestoning of mucosa	Rare	Common
Pseudopolyps	Common	Rare
Small bowel involvement	Minimal	Common
Complications		
Fistulas	Rare	Common
Strictures	Occasional	Common
Anal abscesses	Rare	Common
Perforation	Common (because of toxic megacolon)	Common (because inflammation involves entire bowel wall)
Toxic megacolon	Relatively more common	Rare
Carcinoma	Increased incidence of colorectal cancer after 10 yr of disease	Increased incidence of small intestinal cancer Increased incidence of colorectal cancer but not as much as with ulcerative colitis
Recurrence after surgery	Cure with colectomy	Common at site of anastomosis

*Second peak in incidence after age 60.

usually limited to the colon. Crohn's disease can involve any segment of the GI tract from the mouth to the anus.

Both ulcerative colitis and Crohn's disease commonly occur during the teenage years and early adulthood, and both have a second peak in the sixth decade. IBD is more prevalent in industrialized countries and in Ashkenazi Jews. Many people with IBD have a family member with the disorder.

Etiology and Pathophysiology

IBD is an autoimmune disease involving an immune reaction to a person's own intestinal tract. Some agent or a combination of agents triggers an overactive, inappropriate, sustained immune response. The resulting inflammation causes widespread tissue destruction.

Evidence suggests that IBD is caused by a combination of factors, including environmental factors, genetic predisposition, and alterations in the function of the immune system.[24] Environmental factors such as diet, hygiene, stress, smoking, and nonsteroidal antiinflammatory drugs (NSAIDs) increase susceptibility by influencing the environment of the microbial flora and the immune system. IBD is more prevalent in industrialized regions of the world. Whether diet or other factors unique to Western countries contribute to the development of IBD is not known.[25,26] Specific dietary components have not been identified. However, high dietary intake of total fats, polyunsaturated fatty acid (PUFA), omega-6 fatty acids, and meat is associated with an increased risk of IBD.[26] High fiber and fruit intake is associated with decreased risk of Crohn's disease, whereas vegetable intake is associated with decreased risk of ulcerative colitis.[27]

CULTURAL & ETHNIC HEALTH DISPARITIES

Inflammatory Bowel Disease

- Incidence is about four times higher among whites than in other ethnic groups.
- It has the highest incidence among the Ashkenazi Jewish people and those of middle European origin.

Genetic Link

IBD occurs more frequently in whites (particularly those of Jewish descent) and in family members of persons with IBD (especially monozygotic twins). Genetic predisposition has been confirmed by numerous genome-wide association studies.[24] Certain genetic mutations are associated with Crohn's disease, others are associated with ulcerative colitis, and many are associated with both.

Recently, the first gene associated with Crohn's disease, the *NOD2* gene, was identified. Research is ongoing to understand how defects in the *NOD2* gene lead to Crohn's disease and into finding the other genes that cause IBD.

The discovery of numerous gene variations suggests that IBD is a group of diseases that produce similar types of destruction of the mucosa. A genetically susceptible person who is never exposed to the triggering agent will not become ill, and a person

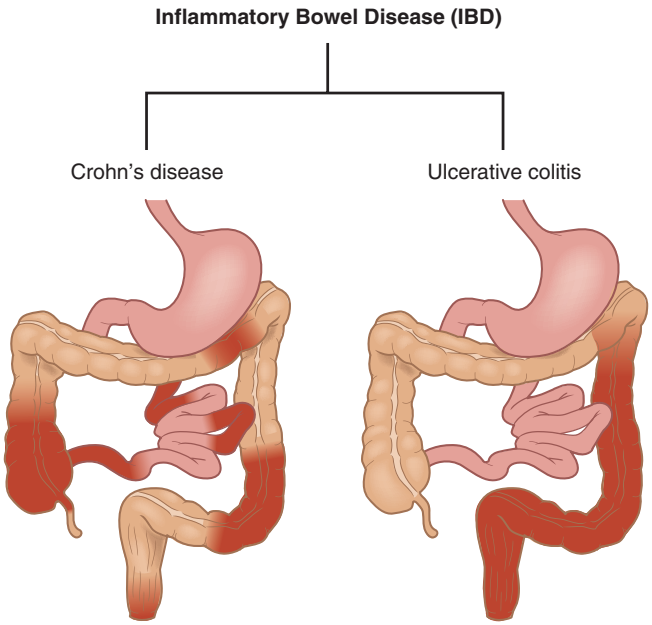

FIG. 43-3 Comparison of distribution patterns of Crohn's disease and ulcerative colitis.

who is not genetically susceptible will not develop IBD even if exposed to the triggering agent. The pathway from genetic mutation to abnormal immune responses varies depending on which gene or genes are affected. This genetic variation may explain differences in patient responses to various pharmacologic therapies for IBD.

Pattern of Inflammation in Ulcerative Colitis Versus Crohn's Disease. The pattern of inflammation differs between Crohn's disease and ulcerative colitis (Fig. 43-3). In Crohn's disease the inflammation involves all layers of the bowel wall. Crohn's disease can occur anywhere in the GI tract from the mouth to the anus, but occurs most commonly in the terminal ileum and colon. Furthermore, segments of normal bowel can occur between diseased portions, the so-called skip lesions (see Table 43-14). Typically, ulcerations are deep and longitudinal and penetrate between islands of inflamed edematous mucosa, causing the classic cobblestone appearance. Strictures at the areas of inflammation may cause bowel obstruction. Since the inflammation goes through the entire wall, microscopic leaks can allow bowel contents to enter the peritoneal cavity and form abscesses or produce peritonitis.

In Crohn's disease, fistulas can develop between adjacent areas of bowel, between the bowel and the bladder, and between the bowel and the vagina. Fistulas can also form a tract through the skin to the outside of the body. Urinary tract infections are usually the first sign of a bowel or bladder fistula, and feces is sometimes seen in the urine. Fistulas between the bowel and the vagina allow feces to leak out through the vagina, and feces leaks onto the skin if there is a skin fistula.

Ulcerative colitis usually starts in the rectum and moves in a continual fashion toward the cecum. Although sometimes mild inflammation occurs in the terminal ileum, ulcerative colitis is a disease of the colon and rectum (see Fig. 43-3). The inflammation and ulcerations occur in the mucosal layer, the innermost layer of the bowel wall. Since it does not extend through all bowel wall layers, fistulas and abscesses are rare. Water and electrolytes cannot be absorbed through inflamed mucosa. Diarrhea with large fluid and electrolyte losses is a characteristic feature of damage to the colonic mucosa epithelium. Breakdown of cells results in protein loss through the stool. Areas of inflamed mucosa form *pseudopolyps,* tongue-like projections into the bowel lumen.

TABLE 43-15 EXTRAINTESTINAL COMPLICATIONS OF IBD

- Joints
  - Peripheral arthritis (colitic)
  - Ankylosing spondylitis
  - Sacroiliitis

  - Conjunctivitis
  - Uveitis
  - Episcleritis
- Gallstones
- Kidney stones
- Liver disease: primary sclerosing cholangitis
- Osteoporosis
- Thromboembolism

Clinical Manifestations

In ulcerative colitis and Crohn's disease, manifestations are often the same (diarrhea, bloody stools, weight loss, abdominal pain, fever, and fatigue). Bloody stools are more common with ulcerative colitis, and weight loss is more common in Crohn's disease because inflammation of the small intestine impairs nutrient absorption. Both forms of IBD are chronic disorders with mild to severe acute exacerbations that occur at unpredictable intervals over many years.

In Crohn's disease, diarrhea and crampy abdominal pain are common symptoms. If the small intestine is involved, weight loss occurs from malabsorption. Rectal bleeding sometimes occurs with Crohn's disease, although not as often as with ulcerative colitis.

In ulcerative colitis, the primary manifestations are bloody diarrhea and abdominal pain. Pain may vary from the mild lower abdominal cramping associated with diarrhea to severe, constant pain associated with acute perforations. With *mild disease,* diarrhea may consist of no more than four semiformed stools daily that contain small amounts of blood. The patient may have no other manifestations. In *moderate disease* the patient has increased stool output (up to 10 stools/day), increased bleeding, and systemic symptoms (fever, malaise, mild anemia, anorexia). In *severe disease,* diarrhea is bloody, contains mucus, and occurs 10 to 20 times a day. In addition, fever, rapid weight loss greater than 10% of total body weight, anemia, tachycardia, and dehydration are present.

Complications

Patients with IBD experience both local (confined to the GI tract) and systemic (extraintestinal) complications (Table 43-15). GI tract complications include hemorrhage, strictures, perforation (with possible peritonitis), fistulas, and colonic dilation (toxic megacolon). Patients with toxic megacolon are at risk of perforation and may need an emergency colectomy. Toxic megacolon is more common with ulcerative colitis. Hemorrhage may lead to anemia and is corrected with blood transfusions and iron supplements. Perineal abscess and fistulas occur in up to a third of patients with Crohn's disease. Some patients develop skin tags around the anus. The incidence and severity of *C. difficile* infection in patients with IBD are increasing.[27]

Nutritional problems are especially common in Crohn's disease when the terminal ileum is involved. Bile salts and cobalamin are exclusively absorbed in the terminal ileum. Thus disease in the terminal ileum can result in fat malabsorption and anemia.

Patients with a history of IBD are considered at increased or high risk for colorectal cancer. In addition, those with Crohn's disease are at increased risk for small intestinal cancer. Screening for cancer at regular intervals is important in persons with IBD.[28]

Some people with IBD suffer from systemic complications, including joint, eye, mouth, kidney, bone, vascular, and skin problems (see Table 43-15). Circulating factors such as cytokines trigger inflammation in these areas. Routine liver function tests are important because primary sclerosing cholangitis, a complication of IBD, can lead to liver failure.

Diagnostic Studies

The diagnosis of IBD includes ruling out other diseases with similar symptoms and then determining whether the patient has Crohn's disease or ulcerative colitis. In early Crohn's disease the symptoms can be similar to those of IBS. Diagnostic studies also provide information about disease severity and complications. A CBC typically shows iron-deficiency anemia from blood loss. An elevated WBC count may be an indication of toxic megacolon or perforation. Decreased serum sodium, potassium, chloride, bicarbonate, and magnesium levels are due to fluid and electrolyte losses from diarrhea and vomiting. Hypoalbuminemia is present with severe disease as a result of poor nutrition or protein loss. Elevated erythrocyte sedimentation rate, C-reactive protein, and WBCs reflect inflammation. Stool cultures are obtained to determine if infection is present. The stool is examined for blood, pus, and mucus.

Imaging studies such as double-contrast barium enema, small bowel series (small bowel follow through), transabdominal ultrasound, CT, and MRI are useful for the diagnosis of IBD. Colonoscopy allows for examination of the entire large intestine lumen and sometimes the most distal ileum. The extent of inflammation, ulcerations, pseudopolyps, and strictures is determined, and biopsy specimens are taken for a definitive diagnosis. Since a colonoscope can enter only the distal ileum, capsule endoscopy (see Chapter 39) may be used in the diagnosis of Crohn's disease in the small intestine.[29] However, biopsies cannot be obtained with either capsule endoscopy or barium enema.

Collaborative Care

The goals of treatment are to (1) rest the bowel, (2) control the inflammation, (3) combat infection, (4) correct malnutrition, (5) alleviate any stress, (6) provide symptomatic relief, and (7) improve quality of life. Since the cause is unknown, treatment relies on drugs to treat the inflammation and maintain a remission. A variety of drugs are available to treat IBD (Tables 43-16 and 43-17). Hospitalization is indicated if the patient fails to respond to drug therapy, if the disease is severe, and if complications are suspected. Since recurrence rate is high after surgical treatment of Crohn's disease, drugs are the preferred treatment.

Drug Therapy. The goals of drug treatment for IBD are to induce and then maintain a remission. Five major classes of medications used to treat IBD are aminosalicylates, antimicrobials, corticosteroids, immunosuppressants, and biologic and targeted therapy (see Table 43-17). Drugs are chosen based on the location and severity of inflammation. Depending on the severity of the disease, patients are treated with either a "step-down" or "step-up" approach. The step-up approach uses less toxic therapies (e.g., aminosalicylates and antimicrobials) first, and more toxic medications (e.g., biologic and targeted therapy) are started when initial therapies do not work. The step-down approach uses biologic and targeted therapy first.

TABLE 43-16 COLLABORATIVE CARE

Inflammatory Bowel Disease

Diagnostic
- History and physical examination
- CBC, erythrocyte sedimentation rate
- Serum chemistries
- Testing of stool for occult blood
- Testing of stool for infection
- Capsule endoscopy
- Radiologic studies with barium contrast
- Sigmoidoscopy and colonoscopy with biopsy

Collaborative Therapy
- High-calorie, high-vitamin, high-protein, low-residue, lactose-free (if lactase deficiency) diet
- Drug therapy (see Table 43-17)
  - Aminosalicylates
  - Antimicrobials
  - Corticosteroids
  - Immunosuppressants
  - Biologic and targeted therapy (immunomodulator)
- Elemental diet or parenteral nutrition
- Physical and emotional rest
- Referral for counseling or support group
- Surgery (see Table 43-18)

Sulfasalazine (Azulfidine) contains sulfapyridine and 5-aminosalicylic acid (5-ASA). The 5-ASA accounts for its therapeutic benefits for IBD. Its exact mechanism of action is unknown, but topical application to the intestinal mucosa suppresses proinflammatory cytokines and other inflammatory mediators. When given orally, 5-ASA alone is absorbed before it reaches the lower GI tract where it is needed. When combined with sulfapyridine, 5-ASA reaches the colon. Because many people cannot tolerate sulfapyridine, preparations such as olsalazine (Dipentum), mesalamine (Pentasa), and balsalazide (Colazal) deliver 5-ASA to the terminal ileum and the colon. These drugs are as effective as sulfasalazine and better tolerated when administered orally.

DRUG ALERT: Sulfasalazine (Azulfidine)
- May cause yellowish orange discoloration of skin and urine.
- Avoid exposure to sunlight and ultraviolet light until photosensitivity is determined.

Preparations with 5-ASA can be administered rectally as suppositories, enemas, and foams. Topical treatment offers the advantage of delivering the 5-ASA directly to the tissue where it is needed and minimizes systemic effects. Aminosalicylates are also first-line therapies for mild to moderate Crohn's disease, especially when the colon is involved, but are more effective for ulcerative colitis. These drugs are recommended for both achieving and maintaining a remission.

Although no specific infectious agent has been identified, antimicrobials (e.g., metronidazole, ciprofloxacin [Cipro]) are used to treat IBD. Corticosteroids such as prednisolone and budesonide (Entocort) are used to achieve remission in IBD.

TABLE 43-17 DRUG THERAPY

Inflammatory Bowel Disease

Class	Action	Examples
5-Aminosalicylates (5-ASA)	Decrease GI inflammation through direct contact with bowel mucosa	*Systemic:* sulfasalazine (Azulfidine), mesalamine (Asacol, Pentasa), olsalazine (Dipentum), balsalazide (Colazal) *Topical:* 5-ASA enema (Rowasa), mesalamine suppositories (Canasa)
Antimicrobials	Prevent or treat secondary infection	metronidazole (Flagyl), ciprofloxacin (Cipro), clarithromycin (Biaxin)
Corticosteroids	Decrease inflammation	*Systemic:* corticosteroids (prednisone, budesonide [Entocort]) (oral); hydrocortisone or methylprednisolone (IV for severe IBD) *Topical:* hydrocortisone suppository or foam (Cortifoam) or enema (Cortenema)
Immunosuppressants	Suppress immune response	azathioprine (Imuran), 6-mercaptopurine (6-MP), methotrexate, cyclosporine
Biologic and targeted therapy (immunomodulators)	Inhibit the cytokine tumor necrosis factor (TNF) Prevent migration of leukocytes from bloodstream to inflamed tissue	infliximab (Remicade), adalimumab (Humira), certolizumab pegol (Cimzia), golimumab (Simponi) natalizumab (Tysabri)
Antidiarrheals	Decrease GI motility*	diphenoxylate with atropine (Lomotil), loperamide (Imodium)
Hematinics and vitamins	Correct iron-deficiency anemia and promote healing	oral ferrous sulfate or gluconate, iron dextran injection (Imferon), cobalamin, zinc, folate

*Used with caution during severe disease because of potential to produce toxic megacolon.

TABLE 43-18 INDICATIONS FOR SURGICAL THERAPY FOR IBD

- Drainage of abdominal abscess
- Failure to respond to conservative therapy
- Fistulas
- Inability to decrease corticosteroids
- Intestinal obstruction
- Massive hemorrhage
- Perforation
- Severe anorectal disease
- Suspicion of carcinoma

Corticosteroids are given for the shortest possible time because of side effects associated with long-term use. Patients with disease in the left colon, sigmoid, and rectum can be given suppositories, enemas, and foams that deliver the corticosteroid directly to the inflamed tissue with minimal systemic effects. Oral prednisone is given to patients with mild to moderate disease who do not respond to either 5-ASA or topical corticosteroids. IV corticosteroids are reserved for those with severe inflammation. Corticosteroids must be tapered to very low levels when surgery is planned to prevent postoperative complications (e.g., infection, delayed wound healing).

Immunosuppressants (6-mercaptopurine, azathioprine [Imuran]) are given to maintain remission after corticosteroid induction therapy. These drugs require regular CBC monitoring because they can suppress the bone marrow and lead to inflammation of the pancreas or gallbladder. They have a delayed onset of action and are therefore useful for maintenance of remission but not for acute flare-ups.

Methotrexate has also been found to be effective for treatment of Crohn's disease, but patients may suffer flu-like symptoms, bone marrow depression, and liver dysfunction. CBCs and liver enzymes are monitored. Methotrexate should not be used in women who are pregnant because it causes birth defects and fetal death.

Currently there are five major biologic and targeted medications.[30] Four are antitumor necrosis factor (TNF) agents: infliximab (Remicade), adalimumab (Humira), certolizumab pegol (Cimzia) and golimumab (Simponi). The fifth, natalizumab (Tysabri), inhibits leukocyte adhesion by blocking α_4-integrin, an adhesion molecule. TNF is a proinflammatory cytokine that is released during inflammation. Infliximab is a monoclonal antibody to TNF. It is given IV to induce and maintain remission in patients with Crohn's disease and in patients with draining fistulas who do not respond to conventional drug therapy. Adalimumab and certolizumab pegol have effects similar to those of infliximab. Adalimumab is self-administered subcutaneously every 1 to 2 weeks, and certolizumab pegol must be administered subcutaneously by a health care provider every 4 weeks. Golimumab is administered subcutaneously twice the first month and then every 4 weeks. Natalizumab is administered by IV infusion every 28 days.

The biologic and targeted agents do not work for everyone. They are costly and may produce allergic reactions.[30] The anti-TNF agents are immunogenic, meaning that patients receiving them frequently produce antibodies against them. Immunogenicity leads to an acute infusion reaction and delayed hypersensitivity-type reactions. The drugs are most effective when given at regular intervals and must not be discontinued unless the patient cannot tolerate them. If the drug is stopped and then restarted, infusion reactions are likely. Natalizumab is associated with increased risk of infection, hepatotoxicity, and hypersensitivity reactions. Its use requires a special safety monitoring program.

The anti-TNF agents have similar side effects. The most common adverse effects are upper respiratory and urinary tract infections, headaches, nausea, joint pain, and abdominal pain. More serious effects include reactivation of hepatitis and tuberculosis (TB); opportunistic infections; and malignancies, especially lymphoma. Patients must be tested for TB and hepatitis before treatment begins and cannot receive live virus immunizations. Patients must be informed of these risks before beginning therapy and taught methods to prevent infection and recognize early signs and symptoms (e.g., fever, cough, malaise, dyspnea).

Surgical Therapy

Ulcerative Colitis. Indications for surgery for ulcerative colitis are presented in Table 43-18. Since ulcerative colitis affects only the colon, a total proctocolectomy is curative. Surgical procedures used to treat ulcerative colitis include

(1) total proctocolectomy with ileal pouch/anal anastomosis and (2) total proctocolectomy with permanent ileostomy. Surgical procedures for ulcerative colitis can be performed laparoscopically.

Total Proctocolectomy With Ileal Pouch/Anal Anastomosis (IPAA). The most commonly used surgical procedure for ulcerative colitis is a total proctocolectomy with ileal pouch/anal anastomosis (IPAA). In this procedure a diverting ileostomy is performed, and an ileal pouch is created and anastomosed directly to the anus (Fig. 43-4). The two surgical procedures are performed approximately 8 to 12 weeks apart. The initial procedure includes colectomy, rectal mucosectomy, ileal pouch (reservoir) construction, ileoanal anastomosis, and temporary ileostomy. The second surgery involves closure of the ileostomy to direct stool toward the new pouch. Adaptation of the pouch occurs over the next 3 to 6 months, which usually results in a decreased number of bowel movements. The patient is able to control defecation at the anal sphincter. The major complication of this procedure is acute or chronic pouchitis.

Total Proctocolectomy With Permanent Ileostomy. A proctocolectomy with a permanent ileostomy is a one-stage operation involving the removal of the colon, rectum, and anus with closure of the anal opening. The end of the terminal ileum is brought out through the abdominal wall and forms a stoma, or ostomy. The stoma is usually placed in the right lower quadrant below the belt line. With a permanent ileostomy, continence is not possible.

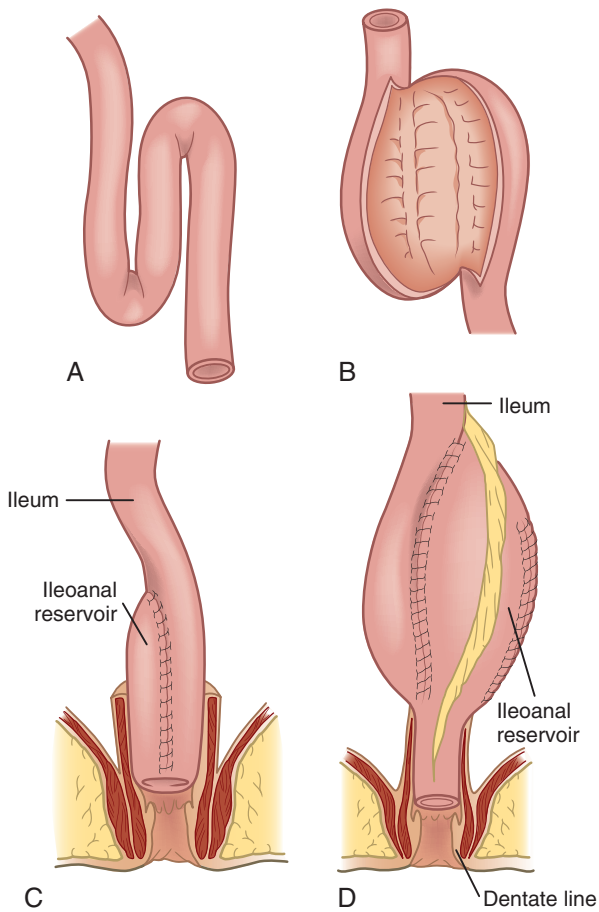

FIG. 43-4 Ileoanal pouch (reservoir). **A,** Formation of a pouch. **B,** Posterior suture lines completed. **C,** J-shaped configuration for ileoanal pouch (J-pouch). **D,** S-shaped configuration for ileoanal pouch (S-pouch).

Crohn's Disease. Surgery for Crohn's disease is usually performed for complications such as strictures, obstructions, bleeding, and fistula (see Table 43-16). Most patients with Crohn's disease eventually require surgery. When segments of the intestine are removed, the remaining intestine is reanastomosed. Unfortunately, the disease often recurs at the anastomosis site.

Repeated removal of sections of small intestine can lead to short bowel syndrome. *Short bowel syndrome* occurs when either surgery or disease leaves too little small intestine surface area to maintain life. Lifetime parenteral nutrition is necessary for survival. (Short bowel syndrome is discussed in this chapter on p. 999.

Conservative surgery is advocated instead of resective surgery in patients with Crohn's disease. Strictures obstructing the bowel can be widened with strictureplasty. If perforation allows bowel contents to drain into the abdominal cavity, the surgeon drains the purulent material, irrigates the abdomen, and makes a temporary ostomy. Abscesses are surgically drained.

Postoperative Care. Postoperative care after surgical procedures for IBD is similar to that described in the general nursing care plan for the postoperative patient (see eNursing Care Plan 20-1 on the website for Chapter 20). If an ileostomy is formed, stoma viability, the mucocutaneous juncture (the area where the mucous membrane of the bowel interfaces with the skin), and peristomal skin integrity must be monitored. (Stoma care is presented later in this chapter on pp. 991-992.)

After surgery, ileostomy output initially may be as high as 1500 to 2000 mL/24 hr. Observe the patient for signs of hemorrhage, abdominal abscess, small bowel obstruction, dehydration, and other related complications. If an NG tube is used, remove it when bowel function returns. Patients, especially those with Crohn's disease, are at risk of early (within 30 days) postoperative bowel obstruction.[31]

Transient incontinence of mucus is a result of intraoperative manipulation of the anal canal. Initial drainage through the ileoanal anastomosis will be liquid. Kegel exercises may help strengthen the pelvic floor and sphincter muscles (see Table 46-19). However, they are not recommended in the immediate postoperative period. Perianal skin care is important to protect the epidermis from mucous drainage and maceration. Instruct the patient to gently clean the skin with a mild cleanser, rinse well, and dry thoroughly. A moisture barrier ointment and a perineal pad may be used.

Nutritional Therapy. Diet is an important component in the treatment of IBD. Consult a dietitian regarding dietary recommendations. The goals of diet management are to (1) provide adequate nutrition without exacerbating symptoms, (2) correct and prevent malnutrition, (3) replace fluid and electrolyte losses, and (4) prevent weight loss.

Nutritional deficiencies are due to decreased oral intake, blood loss, and, depending on the location of the inflammation, malabsorption of nutrients. Patients may reduce food intake in an effort to reduce diarrhea. Inflammatory mediators reduce appetite. Bloody diarrhea leads to iron-deficiency anemia, which is treated with supplemental iron (ferrous sulfate or ferrous gluconate). Parenteral iron may be needed for patients who cannot tolerate oral iron. Iron dextran (Imferon) given intramuscularly by Z-track or IV injection may be necessary if anemia is severe.

Disease of the terminal ileum reduces absorption of cobalamin and bile acids. Reduced cobalamin contributes to anemia, and bile salts are important for fat absorption and contribute to osmotic diarrhea. Cobalamin is available in injection form,

given monthly, or as a daily oral or nasal spray. Cholestyramine, an ion-exchange resin that binds unabsorbed bile salts, helps control the diarrhea. Zinc deficiency can result from severe or chronic diarrhea, and supplementation may be necessary.

Medications can contribute to nutritional problems. Patients receiving sulfasalazine should receive folate (folic acid) daily. Those receiving corticosteroids are prone to osteoporosis and need calcium supplements. Potassium supplements may also be necessary with corticosteroids. Corticosteroids lead to sodium retention, loss of potassium (hypokalemia), and potential toxic megacolon. Vitamin D deficiency is more common in persons with IBD. This may be due to malabsorption due to inflammation, surgical resection of intestine, reduced sunlight exposure, and decreased dietary intake.[32]

Overall, it is essential that people with IBD eat a balanced, healthy diet with sufficient calories, protein, and nutrients. Patients can use MyPlate guidelines to ensure that they get adequate portions from all of the food groups (see Fig. 40-1 and Table 40-1). The diet for each patient must be individualized.

During an acute exacerbation, patients with IBD may not be able to tolerate a regular diet. Liquid enteral feedings are preferred over parenteral nutrition because atrophy of the gut and bacterial overgrowth occur when the GI tract is not used. (Enteral and parenteral nutrition are discussed in Chapter 40.) Enteral nutrition is high in calories and nutrients, lactose free, and easily absorbed. Enteral feedings help achieve remission and improve nutritional status. When regular foods are restarted, they are added gradually to help identify food intolerances or sensitivities.

There are no universal food triggers for IBD, but individuals may find that certain foods cause diarrhea. A food diary helps to identify problem foods to avoid. Because many patients with IBD are lactose intolerant, symptoms improve when milk and milk products are avoided. Lactose-intolerant patients can use yogurt as a substitute. High-fat foods also tend to trigger diarrhea. Cold foods and high-fiber foods (cereal with bran, nuts, raw fruits with peels) may promote diarrhea. Smoking stimulates the GI tract (increases motility and secretion) and should be avoided.

NURSING MANAGEMENT INFLAMMATORY BOWEL DISEASE

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with IBD are presented in Table 43-19.

TABLE 43-19 NURSING ASSESSMENT

Inflammatory Bowel Disease

Subjective Data

Important Health Information

Past health history: Infection, autoimmune disorders
Medications: Antidiarrheal medications

Functional Health Patterns

Health perception–health management: Family history of ulcerative colitis or Crohn's disease; fatigue, malaise
Nutritional-metabolic: Nausea, vomiting; anorexia; weight loss
Elimination: Diarrhea; blood, mucus, or pus in stools
Cognitive-perceptual: Lower abdominal pain (worse before defecation), cramping, tenesmus

Objective Data

General

Intermittent fever, emaciated appearance, fatigue

Integumentary

Pale skin with poor turgor, dry mucous membranes; skin lesions; anorectal irritation, skin tags, cutaneous fistulas

Gastrointestinal

Abdominal distention, hyperactive bowel sounds, abdominal cramps

Cardiovascular

Tachycardia, hypotension

Possible Diagnostic Findings

Anemia; leukocytosis; electrolyte imbalance; hypoalbuminemia; vitamin and trace metal deficiencies; guaiac-positive stool; abnormal sigmoidoscopic, colonoscopic, and/or barium enema findings

NURSING DIAGNOSES

Nursing diagnoses for the patient with IBD include, but are not limited to, the following:

- Diarrhea *related to* bowel inflammation and intestinal hyperactivity
- Imbalanced nutrition: less than body requirements *related to* decreased absorption and increased nutrient loss through diarrhea
- Ineffective coping *related to* chronic disease, lifestyle changes, inadequate confidence in ability to cope

Additional information on nursing diagnoses is presented in eNursing Care Plan 43-2 on the website for this chapter.

PLANNING

The overall goals are that the patient with IBD will (1) have fewer and less severe acute exacerbations, (2) maintain normal fluid and electrolyte balance, (3) be free from pain or discomfort, (4) adhere to medical regimens, (5) maintain nutritional balance, and (6) have an improved quality of life.

NURSING IMPLEMENTATION

During the acute phase, focus your attention on hemodynamic stability, pain control, fluid and electrolyte balance, and nutritional support. Maintain accurate intake and output records, and monitor the number and appearance of stools. It is important to establish rapport and encourage the patient to talk about self-care strategies. An explanation of all procedures and treatment helps to build trust and decrease apprehension.

Because of the relationship between emotions and the GI tract, teach the patient strategies for managing stress (see Chapter 7). Remember that patients experiencing a relapse have been managing their disease and need to feel in control. Ask them what you can do to facilitate their self-care. Once you have established a therapeutic relationship, talk with smokers about quitting, since smoking exacerbates the disease.

IBD is a chronic illness. Given the chronicity and uncertainty related to frequency and severity of flares, the patient may experience frustration, depression, and anxiety. Psychotherapy and behavioral therapies may help the patient experiencing psychologic distress in managing his or her symptoms. Assist the patient in accepting the chronicity of IBD and learning strategies to cope with its recurrent, unpredictable nature. Inadequate coping mechanisms are sometimes result of the childhood onset of the disease before the person has the emotional and developmental maturity needed to cope. Patients may suffer severe fatigue, which limits energy for physical activity. Rest is impor-

tant. Patients may lose sleep because of frequent episodes of diarrhea and abdominal pain. Nutritional deficiencies and anemia leave the patient feeling weak and listless. Schedule activities around rest periods.

Until diarrhea is controlled, help the patient stay clean, dry, and free of odor. Place a deodorizer in the room. Meticulous perianal skin care using plain water (no harsh soap) together with a skin barrier cream prevents skin breakdown. Dibucaine (Nupercainal), witch hazel, or other soothing compresses or prescribed ointment and sitz baths may reduce irritation and discomfort of the anus.

In the majority of patients with IBD the disease is characterized by intermittent exacerbation and remission of symptoms. The patient and caregiver may need help setting realistic short- and long-term goals. Teaching includes (1) the importance of rest and diet management, (2) perianal care, (3) drug action and side effects, (4) symptoms of recurrence of disease, (5) when to seek medical care, and (6) use of diversional activities to reduce stress. Excellent teaching resources written in easily comprehensible language are available from the Crohn's and Colitis Foundation of America *(www.ccfa.org)*.

EVALUATION

The expected outcomes are that the patient with IBD will

- Experience a decrease in the number of diarrhea stools
- Maintain body weight within a normal range
- Be free from pain and discomfort
- Demonstrate the use of effective coping strategies

Additional information on expected outcomes is presented in eNursing Care Plan 43-2 on the website for this chapter.

GERONTOLOGIC CONSIDERATIONS

INFLAMMATORY BOWEL DISEASE

Although IBD is considered a disease of teenagers and young adults, a second peak in occurrence is in the sixth decade. The etiology, natural history, and clinical course of IBD are similar to those observed in younger patients. However, in the older patient with ulcerative colitis, the distal colon (proctitis) is usually involved. Diagnosis is sometimes difficult in older adults, since IBD can be confused with *C. difficile* infection and the colitis associated with diverticulosis or NSAID ingestion. Older adults receive the same medical treatment as younger patients and have similar results after ileoanal reservoir surgery.[33] However, they are more prone to complications from corticosteroids than younger adults.

Collaborative care of the older patient with IBD is similar to care of the younger patient. However, because of increased risk of cardiovascular and pulmonary complications, older adults tend to have increased morbidity associated with surgical procedures.

In addition to Crohn's disease and ulcerative colitis, older adults are also vulnerable to inflammation of the colon (colitis) from drug use and systemic vascular disease. Drugs such as NSAIDs, digitalis, sumatriptan (Imitrex), vasopressin, estrogen, and allopurinol (Zyloprim) have been associated with the development of colitis in the older patient. Colitis may also be secondary to ischemic bowel disease related to atherosclerosis and heart failure.

Older adults, particularly those with diminished renal and cardiovascular function, are more vulnerable to the volume depletion consequences of diarrhea. In older adults with IBD, focus on careful assessment of fluid and electrolyte status and evaluation of the replacement therapies.

INTESTINAL OBSTRUCTION

Intestinal obstruction occurs when intestinal contents cannot pass through the GI tract. The obstruction may occur in the small intestine or colon and can be partial or complete, simple or strangulated.[34] A partial obstruction usually resolves with conservative treatment, whereas a complete obstruction usually requires surgery. A simple obstruction has an intact blood supply, and a strangulated one does not.

TYPES OF INTESTINAL OBSTRUCTION

The causes of intestinal obstruction can be classified as mechanical or nonmechanical.

Mechanical

Mechanical obstruction is a detectable occlusion of the intestinal lumen. Most intestinal obstructions occur in the small intestine.[34] Surgical adhesion is the most common cause of small bowel obstructions and can occur within days of surgery or several years later (Fig. 43-5). Other causes of intestinal obstruction are hernia, strictures from Crohn's disease, and intussusception following bariatric abdominal surgery. The most common cause of colon obstruction is cancer, followed by diverticular disease.

Nonmechanical

Nonmechanical obstruction may result from a neuromuscular or vascular disorder. **Paralytic (adynamic) ileus** (lack of intestinal peristalsis and bowel sounds) is the most common form of nonmechanical obstruction. It occurs to some degree after any abdominal surgery. It can be difficult to know whether postoperative obstruction is due to paralytic ileus or adhesions. One clue is that bowel sounds usually return before postoperative adhesions develop. Other causes of paralytic ileus include peritonitis, inflammatory responses (e.g., acute pancreatitis, acute appendicitis), electrolyte abnormalities (especially hypokalemia), and thoracic or lumbar spinal fractures.

Pseudo-obstruction is a mechanical obstruction of the intestine without demonstration of obstruction by radiologic methods. Collagen vascular diseases and neurologic and endocrine disorders may cause pseudo-obstruction, but many times the cause is unknown.

Vascular obstructions are rare and are the result of an interference with the blood supply to a portion of the intestines. The most common causes are emboli and atherosclerosis of the mesenteric arteries. Emboli may originate from thrombi in patients who have chronic atrial fibrillation, diseased heart valves, and prosthetic valves. Venous thrombosis may be seen in conditions of low blood flow, such as heart failure and shock.

Etiology and Pathophysiology

About 6 to 8 L of fluid enter the small intestine daily. Most of the fluid is absorbed before it reaches the colon. Approximately 75% of intestinal gas is swallowed air. When an obstruction occurs, fluid, gas, and intestinal contents accumulate proximal to the obstruction, and the distal bowel collapses. The distention reduces the absorption of fluids and stimulates intestinal secretions. The proximal bowel becomes increasingly distended, and

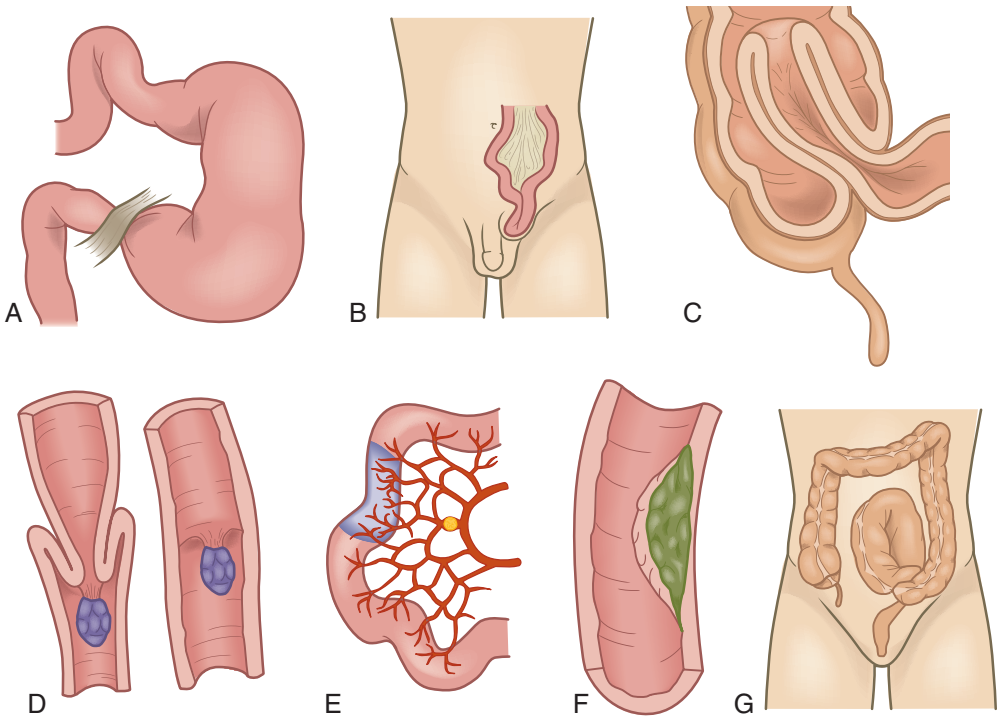

FIG. 43-5 Bowel obstructions. **A,** Adhesions. **B,** Strangulated inguinal hernia. **C,** Ileocecal intussusception. **D,** Intussusception from polyps. **E,** Mesenteric occlusion. **F,** Neoplasm. **G,** Volvulus of the sigmoid colon.

intraluminal bowel pressure rises. The increased pressure leads to an increase in capillary permeability and extravasation of fluids and electrolytes into the peritoneal cavity. Retention of fluids in the intestine and peritoneal cavity (third spacing) leads to a severe reduction in circulating blood volume and results in hypotension and hypovolemic shock.

If blood flow is inadequate, bowel tissue becomes ischemic, then necrotic, and the bowel may perforate. In the most dangerous situation the bowel becomes so distended that the blood flow stops, causing edema, cyanosis, and gangrene of a bowel segment. This is called *intestinal strangulation* or *intestinal infarction.* If it is not corrected quickly, the bowel will become necrotic and rupture, leading to infection, septic shock, and death.

The location of the obstruction determines the extent of fluid, electrolyte, and acid-base imbalances. If the obstruction is high (e.g., upper duodenum), metabolic alkalosis may result from the loss of gastric hydrochloric (HCl) acid through vomiting or NG intubation and suction. When the obstruction is located in the small intestine, dehydration occurs rapidly. Dehydration and electrolyte imbalances do not occur early in large bowel obstruction. If the obstruction is below the proximal colon, solid fecal material accumulates until symptoms of discomfort appear.

Some small intestine obstructions, especially those due to surgical adhesions, may resolve without surgery.[34] Other small intestine obstructions, such as strangulated obstructions, require emergency surgery for survival. *Volvulus* is an intestinal obstruction that occurs by the bowel twisting on itself (see Fig. 43-5). Malignant bowel obstructions are associated with colorectal and ovarian cancer.

Clinical Manifestations

The clinical manifestations of intestinal obstruction vary, depending on its location (Table 43-20). The most important early manifestations of a small bowel obstruction are colicky abdominal pain, nausea, vomiting, and abdominal distention. Constipation and decreased flatus occur later. Patients with obstructions in the proximal small intestine rapidly develop nausea and vomiting, which is sometimes projectile and contains bile. Vomiting from more distal obstructions of the small intestine is more gradual in onset. Foul-smelling vomitus that looks like stool indicates a long-standing obstruction requiring immediate surgery. Signs of colonic obstruction include abdominal distention, constipation (new onset), and lack of flatus.

Vomiting usually relieves abdominal pain in higher intestinal obstructions. Persistent, colicky abdominal pain is seen in patients with lower intestinal obstruction. With mechanical obstruction, pain generally comes and goes in waves. In contrast, paralytic ileus produces a more constant, generalized abdominal discomfort. Strangulation causes severe, constant pain that is rapid in onset. Abdominal distention is usually absent or minimally noticeable in proximal small intestine obstructions and markedly increased in lower intestinal obstructions. Abdominal tenderness and rigidity are usually absent unless strangulation or peritonitis has occurred.

TABLE 43-20 MANIFESTATIONS OF SMALL AND LARGE INTESTINAL OBSTRUCTIONS

Manifestation	Small Intestine	Large Intestine
Onset	Rapid	Gradual
Vomiting	Frequent and copious	Rare
Pain	Colicky, cramplike, intermittent pain	Low-grade, cramping abdominal pain
Bowel movement	Feces for a short time	Absolute constipation
Abdominal distention	Greatly increased	Increased

Auscultation of bowel sounds reveals high-pitched sounds above the area of obstruction. Bowel sounds may also be absent. The patient often notes *borborygmi* (audible abdominal sounds produced by hyperactive intestinal motility). The patient's temperature rarely rises above 100° F (37.8° C) unless strangulation or peritonitis occurs.

Diagnostic Studies

Perform a thorough history and physical examination. CT scans and abdominal x-rays are ordered. Sigmoidoscopy or colonoscopy may provide direct visualization of an obstruction in the colon.

A CBC and blood chemistries may be performed. An elevated WBC count may indicate strangulation or perforation. Elevated hematocrit values may reflect hemoconcentration. Decreased hemoglobin and hematocrit values may indicate bleeding from a neoplasm or strangulation with necrosis. Serum electrolytes, BUN, and creatinine are monitored frequently to assess the degree of dehydration. Metabolic alkalosis can develop as a result of vomiting.

Collaborative Care

Emergency surgery is performed if the bowel is strangulated, but many bowel obstructions resolve with conservative treatment. Initial medical treatment of bowel obstruction caused by adhesions includes placing the patient on NPO status, inserting an NG tube for decompression, providing IV fluid therapy with either normal saline or lactated Ringer's solution (since fluid losses from the GI tract are isotonic), adding potassium to IV fluids after verifying renal function, and administering analgesics for pain control.

The treatment goal for the patient with a malignant bowel obstruction is to regain patency and resolve the obstruction. Stents can be placed via endoscopic or fluoroscopic procedures. They can be used for palliative purposes or until surgery can be performed. Corticosteroids that have antiemetic properties and decrease edema and inflammation may be used in combination with stent placement. A venting gastrostomy tube may be placed endoscopically or percutaneously.[35]

If the obstruction does not improve within 24 hours or if the patient's condition deteriorates, surgery is performed to relieve the obstruction. In some cases, parenteral nutrition may be used to improve the patient's nutritional status before surgery and promote postoperative healing. Surgery may involve simply resecting the obstructed segment of bowel and anastomosing the remaining healthy bowel back together. Partial or total colectomy, colostomy, or ileostomy may be required when extensive obstruction or necrosis is present.

Occasionally obstructions can be removed nonsurgically. A colonoscope can be used to remove polyps, dilate strictures, and remove and destroy tumors with a laser.

NURSING MANAGEMENT INTESTINAL OBSTRUCTION

NURSING ASSESSMENT

Intestinal obstruction is a potentially life-threatening condition. Major concerns are prevention of fluid and electrolyte deficiencies and early recognition of deterioration in the patient's condition (e.g., hypovolemic shock, bowel strangulation). Nursing assessment begins with a detailed patient history and physical examination. The type and location of obstruction usually cause characteristic symptoms. Determine the location, duration, intensity, and frequency of abdominal pain and whether abdominal tenderness or rigidity is present.

Record the onset, frequency, color, odor, and amount of vomitus. Assess bowel function, including the passage of flatus. Auscultate for bowel sounds and document their character and location. Inspect the abdomen for scars, visible masses, and distention. Measure the abdominal girth, and check for signs of peritoneal irritation (e.g., muscle guarding, rebound pain, pain when the bed is shaken). If the surgeon decides to wait and see if the obstruction resolves on its own, assess the patient regularly and notify the surgeon of changes in vital signs, changes in bowel sounds, decreased urine output, increased abdominal distention, and pain.

Maintain a strict intake and output record, including emesis and tube drainage. A urinary catheter is ordered to monitor hourly urine outputs. Immediately report if the urine output is less than 0.5 mL/kg of body weight per hour because this indicates inadequate vascular volume and the potential for acute kidney injury. Rising serum creatinine and BUN levels are additional indicators of acute kidney injury.

NURSING DIAGNOSES

Nursing diagnoses for the patient with intestinal obstructions include, but are not limited to, the following:

- Acute pain *related to* abdominal distention and increased peristalsis
- Deficient fluid volume *related to* a decrease in intestinal fluid absorption, third space fluid shifts into the bowel lumen and peritoneal cavity, NG suction, and vomiting

PLANNING

The overall goals are that the patient with an intestinal obstruction will have (1) relief of the obstruction and return to normal bowel function, (2) minimal to no discomfort, and (3) normal fluid and electrolyte and acid-base status.

NURSING IMPLEMENTATION

Monitor the patient closely for signs of dehydration and electrolyte imbalances. Administer IV fluids as ordered. Watch for signs and symptoms of fluid overload, since some patients, especially older adults, may not tolerate rapid fluid replacement. Monitor serum electrolyte levels closely. A patient with a high intestinal obstruction is more likely to have metabolic alkalosis. A patient with a low obstruction is at greater risk for metabolic acidosis. The patient is often restless and constantly changes position to relieve the pain. Provide comfort measures and promote a restful environment. Nursing care of the patient after surgery for an intestinal obstruction is similar to care of the patient after a laparotomy (see pp. 970-971).

With an NG tube in place, oral care is extremely important. Vomiting leaves an unpleasant taste in the patient's mouth, and fecal odor may be present. The patient breathes through the mouth, drying the mouth and lips. Encourage and help the patient to brush the teeth frequently. Mouthwash and water for rinsing the mouth and water-soluble lubricant for the lips should be readily available to the patient. Check the nose for signs of irritation from the NG tube. Clean and dry this area daily, apply water-soluble lubricant, and retape the tube. Check the NG tube every 4 hours for patency.

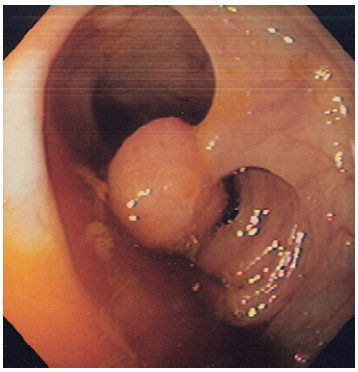

FIG. 43-6 Endoscopic image of pedunculated polyp in descending colon.

POLYPS OF LARGE INTESTINE

Colonic polyps arise from the mucosal surface of the colon and project into the lumen. They may be *sessile* (flat, broad based, and attached directly to the intestinal wall) or *pedunculated* (attached to the intestinal wall by a thin stalk). Polyps tend to be sessile when small and become pedunculated as they enlarge (Fig. 43-6). They may be found anywhere in the large intestine but are most commonly found in the rectosigmoid area. Rectal bleeding and occult blood in the stool are the most common signs. Most patients with polyps are asymptomatic.

Types of Polyps

The most common types of polyps are hyperplastic and adenomatous. *Hyperplastic polyps* are nonneoplastic growths. They rarely grow larger than 5 mm and never cause clinical symptoms. Other benign (nonneoplastic) polyps include inflammatory polyps, lipomas, and juvenile polyps.

Adenomatous polyps are neoplastic. They are closely linked to colorectal adenocarcinoma. The risk of cancer increases with polyp size. Removing adenomatous polyps decreases the occurrence of colorectal cancer.

Genetic Link

Familial adenomatous polyposis (FAP) is the most common polyposis syndrome (see the Genetics in Clinical Practice box). FAP is a genetic disorder characterized by hundreds or sometimes thousands of polyps in the colon that eventually become cancerous, usually by age 40. Since it is autosomal dominant, 50% of the offspring of a patient with FAP carry the FAP gene. Anyone with a family history of FAP should undergo genetic testing during childhood. If the FAP gene is present, colorectal screening begins at puberty, and annual colonoscopy begins at age 16. Since cancer is inevitable, the colon and rectum are removed, usually by age 25, and proctocolectomy with an IPAA or an ileostomy is performed (see p. 980). Patients with FAP are also at risk for cancers of the thyroid, small bowel, liver, and brain, so lifetime cancer surveillance is essential.[36]

Diagnostic Studies and Collaborative Care

Colonoscopy, sigmoidoscopy, barium enema, and virtual colonoscopy (CT or MRI colonography) are used to discover polyps. All polyps are considered abnormal and should be removed. Colonoscopy is preferred because it allows evaluation of the total colon, and polyps can be removed immediately *(polypectomy)*. Polyps can be detected but not removed during barium enema and virtual colonoscopy. If the polyp is not removable during the colonoscopy, a biopsy specimen is taken to stage the cancer in preparation for surgery. After polypectomy, observe the patient for rectal bleeding, fever, severe abdominal pain, and abdominal distention, which may indicate hemorrhage or perforation.

GENETICS IN CLINICAL PRACTICE

Familial Adenomatous Polyposis (FAP)

Genetic Basis

- Classic form of disease
  - Autosomal dominant disorder.
  - Mutations in adenomatous polyposis coli *(APC)* gene.
  - Normally this is a tumor suppressor gene involved in DNA repair.
  - Normally this gene produces a special substance (a protein) that keeps polyps from developing in the colon.
- Autosomal recessive FAP
  - Autosomal recessive disorder.
  - Mutations in the *mutY* homolog *(MUTYH)* gene.
  - Normally this gene is involved in DNA repair.

Incidence

- Affects 1 in 6800 to 30,000 people.
- Men and women are affected equally.

Genetic Testing

- DNA testing is available.

Clinical Implications

- Accounts for at least 1% of all colorectal cancers.
- Classic FAP is characterized by colorectal polyps (usually hundreds to thousands).
- Polyps are not present at birth but appear during adolescence and early adulthood.
- Autosomal recessive FAP is characterized by fewer polyps, typically <100.
- If untreated, classic FAP almost always results in the development of colorectal cancer before age 40.
- With classic FAP, other benign and malignant tumors are sometimes found, especially in the duodenum, stomach, bones, skin, and other tissues.
- Many deaths related to FAP could be prevented with early and aggressive monitoring and treatment, including frequent colonoscopies and total colectomy.
- Individuals with a family history of FAP could benefit from genetic counseling.

COLORECTAL CANCER

Colorectal cancer (CRC) is the third most common form of cancer and responsible for 9% of cancer deaths. It is estimated that annually about 103,170 Americans are diagnosed with CRC.[28] The incidence of CRC is presented in eFig. 43-1 on the website for this chapter.

CRC is more common in men than in women. Mortality rates are highest among African American men and women. The risk of CRC increases with age, with about 90% of new CRC cases detected in people older than 50. However, the incidence of CRC in individuals over 50 is decreasing due to increased screening to detect precancerous lesions.

Etiology and Pathophysiology

Risk factors for CRC include a diet high in red or processed meat, obesity, physical inactivity, alcohol, long-term smoking,

CULTURAL & ETHNIC HEALTH DISPARITIES

Colorectal Cancer

- African Americans are at the highest risk compared with other ethnic groups.
- Incidence is declining in the United States except among African American men.
- Among Asian Americans, this is the second most commonly diagnosed cancer, and it is the third most frequent cause of cancer-related death.

and low intake of fruits and vegetables.[28] Genetic conditions such as FAP and a personal history of IBD place an individual at risk for CRC. About one third of cases of CRC occur in patients with a family history of CRC.

Hereditary diseases (e.g., FAP) account for about 5% to 10% of CRC cases. Hereditary nonpolyposis colorectal cancer (HNPCC) syndrome (also called Lynch syndrome) is the most common form of hereditary CRC (see the Genetics in Clinical Practice box).

Physical exercise and a diet with large amounts of fruits, vegetables, and grains may decrease the risk of CRC. Long-term use of NSAIDs (e.g., aspirin) is associated with reduced CRC risk. (See Table 43-21 for a list of risk factors.)

Adenocarcinoma is the most common type of CRC. Typically it begins as adenomatous polyps. Approximately 85% of CRCs arise from adenomatous polyps (see Fig. 43-6).

As the tumor grows, the cancer invades and penetrates the muscularis mucosae (see eFig. 43-2 on the website for this chapter). Eventually tumor cells gain access to the regional lymph nodes and vascular system and spread to distant sites. (The stages of tumor growth are shown in Fig. 43-7.) Since

GENETICS IN CLINICAL PRACTICE

Hereditary Nonpolyposis Colorectal Cancer (HNPCC) or Lynch Syndrome

Genetic Basis
- Autosomal dominant disorder.
- Mutations in *MSH2, MLH1, MSH6, PMS2* genes.
- These genes are involved in repair of mistakes when DNA is replicated.

Incidence
- Affects 1 in 500 to 2000 people.

Genetic Testing
- DNA testing is available.

Clinical Implications
- Accounts for 5% of all colorectal cancers.
- Individual with genetic mutation has 80% to 90% lifetime risk of developing colorectal cancer.
- People with HNPCC have an increased risk of cancers of stomach, small intestine, liver, gallbladder, upper urinary tract, brain, skin, and prostate. Occasionally, people with HNPCC also have colon polyps, which occur at an earlier age than do colon polyps in the general population and are more prone to become malignant.
- Individuals with known genetic mutations need to be monitored with colonoscopy every year.
- Women with HNPCC also have a greatly increased risk of endometrial and ovarian cancer.
- Examination by pelvic ultrasound and endometrial biopsy should also be considered to screen for endometrial cancer.

TABLE 43-21 RISK FACTORS FOR COLORECTAL CANCER

- Family history of colorectal cancer (first-degree relative)
- Personal history of inflammatory bowel disease
- Personal history of colorectal cancer
- Family or personal history of familial adenomatous polyposis (FAP)
- Family or personal history of hereditary nonpolyposis colorectal cancer (HNPCC) syndrome
- Obesity (body mass index ≥30 kg/m^2)
- Red meat (≥7 servings/wk)
- Cigarette smoking
- Alcohol (≥4 drinks/wk)

venous blood leaving the colon and rectum flows through the portal vein and the inferior rectal vein, the liver is a common site of metastasis. The cancer spreads from the liver to other sites, including the lungs, bones, and brain. CRC can also spread directly into adjacent structures.

Clinical Manifestations

CRC has an insidious onset, and symptoms do not appear until the disease is advanced. Common clinical manifestations include iron-deficiency anemia, rectal bleeding, abdominal pain, change in bowel habits, and intestinal obstruction or perforation.

Physical findings may include the following:
- *Early disease:* Nonspecific findings (fatigue, weight loss) or none at all
- *More advanced disease:* Abdominal tenderness, palpable abdominal mass, hepatomegaly, ascites

Right-sided lesions are more likely to bleed and cause diarrhea, while left-sided tumors are usually detected later and could present with bowel obstruction (Fig. 43-8).

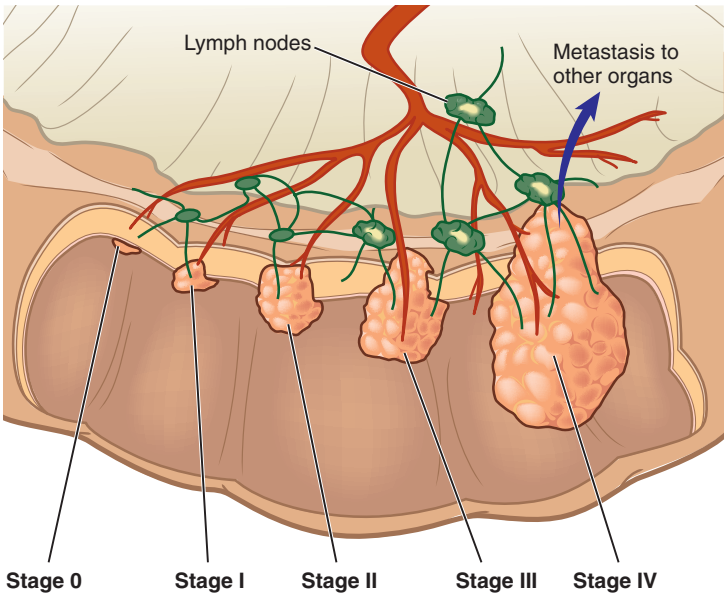

FIG. 43-7 The five stages of colorectal cancer. Stage 0 cancer has not grown beyond the mucosal layer. Stage I cancer has grown beyond the mucosa into the submucosa, but no lymph nodes are involved. Stage II cancer has grown beyond the submucosa into the muscle but there is no lymph node involvement or metastasis. Stage III cancer is any tumor with lymph node involvement but no metastasis. Stage IV cancer is any tumor with lymph node involvement and metastasis.

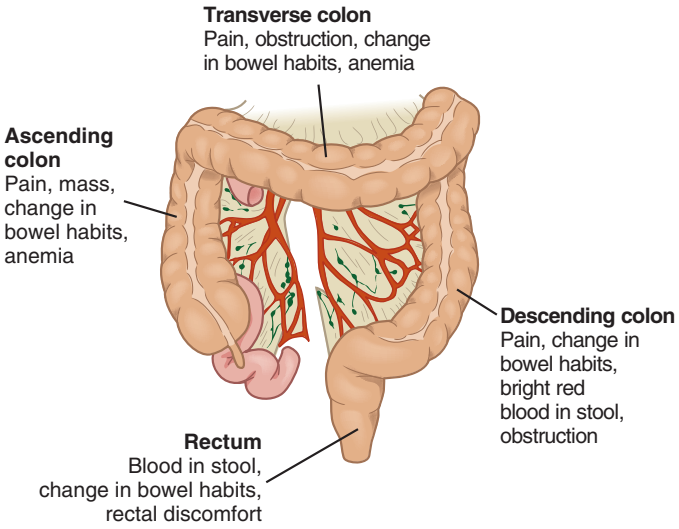

FIG. 43-8 Signs and symptoms of colorectal cancer by location of primary cancer.

Due to increased emphasis on screening practices, colon cancer is now often detected during screening procedures. Complications of CRC include obstruction, bleeding, perforation, peritonitis, and fistula formation.

Diagnostic Studies

Obtain a thorough history with close attention to family history (Table 43-22). Since symptoms of CRC do not become evident until the disease is advanced, regular screening is advocated to detect and remove polyps before they become cancerous. Beginning at age 50, both men and women at average risk for developing CRC should have screening tests to detect both polyps and cancer based on one of these testing schedules.[28]

Tests that find polyps and cancer include the following:

- Flexible sigmoidoscopy (done every 5 years)
- Colonoscopy (done every 10 years)
- Double-contrast barium enema (done every 5 years)
- CT colonography (virtual colonoscopy) (done every 5 years)

Tests that primarily find cancer include the following:

- Fecal occult blood test (FOBT) (done every year)
- Fecal immunochemical test (FIT) (done every year)

Colonoscopy is the gold standard for CRC screening because the entire colon is examined (only 50% of CRCs are detected by sigmoidoscopy), biopsies can be obtained, and polyps can be immediately removed and sent to the laboratory for examination. People at average risk of CRC should have a colonoscopy every 10 years beginning at age 50, except for African Americans, who should have the first colonoscopy at age 45.[37]

Less favorable, but acceptable, screening methods include testing the stool for fecal blood. The FOBT and FIT look for blood in the stool. Stool tests must be done frequently, since tumor bleeding occurs at intervals and may easily be missed if a single test is done.

Persons at risk (see Table 43-21) should begin screening earlier and have screening done more often. Those who have a first-degree relative who developed CRC before age 60 or have two first-degree relatives with CRC should have a colonoscopy every 5 years beginning at age 40 or 10 years earlier than the youngest relative developed cancer. However, those who have one first-degree relative who had CRC after age 60 should have the same screening as the average at-risk person.

Once colonoscopy and tissue biopsies confirm the diagnosis of CRC, additional laboratory studies are done, including a CBC to check for anemia, coagulation studies, and liver function tests. A CT scan or MRI of the abdomen may be helpful in detecting liver metastases, retroperitoneal and pelvic disease, and depth of penetration of tumor into the bowel wall. However, liver function tests may be normal even when metastasis has occurred.

Carcinoembryonic antigen (CEA) is a complex glycoprotein sometimes produced by CRC cells. It may be used to monitor for disease recurrence after surgery or chemotherapy, but is not a good screening tool because of the large number of false positives.

Collaborative Care

The prognosis and treatment of CRC correlate with pathologic staging of the disease. The most commonly used staging system is the tumor, node, metastasis (TNM) staging (Table 43-23). As with other cancers, prognosis worsens with greater size and

TABLE 43-22 COLLABORATIVE CARE

Colorectal Cancer

Diagnostic	Collaborative Therapy
• History and physical examination • Digital rectal examination • Testing of stool for occult blood • Barium enema • Sigmoidoscopy • Colonoscopy • CBC • Liver function tests • CT scan of abdomen • MRI • Ultrasound • Carcinoembryonic antigen (CEA) test	• Surgery • Right hemicolectomy • Left hemicolectomy • Abdominal-perineal resection • Laparoscopic colectomy • Chemotherapy • Targeted therapy • Radiation therapy

TABLE 43-23 TNM CLASSIFICATION OF COLORECTAL CANCER

T	**Primary Tumor**
T_x	Primary tumor cannot be assessed because of incomplete information.
T_{is}	Carcinoma in situ. Cancer is in earliest stage and has not grown beyond mucosa layer.
T_1	Tumor has grown beyond mucosa into the submucosa.
T_2	Tumor has grown through submucosa into muscularis propria.
T_3	Tumor has grown through the muscularis propria into the subserosa but not to neighboring organs or tissues.
T_4	Tumor has spread completely through the colon or rectal wall and into nearby tissues or organs.
N	**Lymph Node Involvement**
N_x	Lymph nodes cannot be assessed.
N_0	No regional lymph node involvement is found.
N_1	Cancer is found in one to three nearby lymph nodes.
N_2	Cancer is found in four or more nearby lymph nodes.
M	**Metastasis**
M_x	Presence of distant metastasis cannot be assessed.
M_0	No distant metastasis is seen.
M_1	Distant metastasis is present.

depth of tumor, lymph node involvement, and metastasis (Table 43-24).

Surgical Therapy. Goals of surgical therapy include (1) complete resection of the tumor together with adequate margins of healthy tissue, (2) a thorough exploration of the abdomen to determine if the cancer has spread, (3) removal of all lymph nodes that drain the area where the cancer is located, (4) restoration of bowel continuity so that normal bowel function will return, and (5) prevention of surgical complications.

Some polyps can be removed during colonoscopy, whereas others require surgery. Polypectomy during colonoscopy can be used to resect CRC in situ and is considered successful when the resected margin of the polyp is free of cancer, the cancer is well differentiated, and there is no apparent lymphatic or blood vessel involvement.

Reduction of colonic bacteria is recommended before surgery to prevent anastomotic leakage of bacteria and to decrease postoperative infection and abscess formation. The bowel is typically cleansed with a polyethylene glycol lavage solution (e.g., MiraLAX, GoLYTELY), and oral antibiotics are given to further decrease the amount of colonic and rectal bacteria.

The site of the CRC dictates the site of the resection (e.g., right hemicolectomy, left hemicolectomy). Surgical removal of stage I cancer includes removal of the tumor and at least 5 cm of intestine on either side of the tumor, plus removal of nearby lymph nodes. The remaining cancer-free ends are sewn back together. Laparoscopic surgery is sometimes used for stage I tumors, especially those in the left colon. Low-risk stage II tumors are treated with wide resection and reanastomosis, but chemotherapy is used in addition to surgery for high-risk stage II tumors.[38] Stage III tumors are treated with surgery and chemotherapy.

Once the cancer has spread to distant sites (stage IV), surgery is palliative and chemotherapy is directed at controlling the spread. Radiation may be used to provide pain relief.

If a patient has a perforation or peritonitis or is hemodynamically unstable, a temporary colostomy may be done. Then later the ends of the colon can be surgically reconnected.

In rectal cancer the surgeon has three major options: (1) local excision, (2) abdominal-perineal resection (APR) with a permanent colostomy, and (3) low anterior resection (LAR) to preserve sphincter function. The surgical decision is based on the location and staging of the cancer and ability to restore normal bowel function and continence. Most patients with rectal cancer require an APR or LAR. The LAR is used more frequently because of the potential for more normal control over defecation. When the tumor is not resectable or metastasis is present, palliative surgery is done to control hemorrhage or relieve a malignant bowel obstruction.

In APR, both the tumor and the entire rectum are removed and the person has a permanent colostomy. The perineal wound may be closed around a drain or left open with packing to allow healing by granulation. Complications that can occur are delayed wound healing, hemorrhage, persistent perineal sinus tracts, infections, and urinary tract and sexual dysfunctions.

An LAR may be indicated for tumors of the rectosigmoid and the mid to upper rectum. If the tumor is far enough from the anal sphincters, the sphincters may be left intact. The use of end-to-end anastomosis staplers has allowed lower (less than 5 cm from anus) and more secure anastomoses.

If the rectum is removed and the anal sphincters remain, an alternative reservoir with either a colonic J-pouch or coloplasty can be made. The colonic J-pouch is created by folding the distal colon back on itself and suturing it to form a pouch, which replaces the rectum as a reservoir for stool. The patient has a temporary colostomy to allow the J-pouch sutures time to heal before stool enters it. *Coloplasty* is an alternative to the pouch. It is created by slitting the side of a section of colon a short distance proximal to the anus, stretching the colon transversely to make it wider, and then suturing it closed in the new widened position. Patients with sphincter-sparing procedures may experience diarrhea, constipation, and incontinence even years after the procedure. The colonic J-pouch has decreased diarrhea and incontinence problems, but patients may have difficulty evacuating stool.

Chemotherapy and Targeted Therapy. Chemotherapy can be used to shrink the tumor before surgery, as an adjuvant therapy after colon resection, and as palliative treatment for nonresectable cancer. Adjuvant chemotherapy is recommended for patients with stage III tumors and high-risk stage II tumors. Current chemotherapy protocols include 5-fluorouracil (5-FU) and folinic acid (leucovorin) alone or in combination with oxaliplatin (Eloxatin). The preferred protocol includes oxaliplatin, but it may be omitted for patients who have too many side effects. Oral fluoropyrimidines (e.g., capecitabine [Xeloda]) have been found as effective as 5-FU/folinic acid monotherapy and can also be given in combination with oxaliplatin.[38]

DRUG ALERT: Capecitabine (Xeloda)
- Instruct patient not to get immunizations without physician's approval.
- Report temperature >100.4° F (38° C) immediately.

A variety of targeted therapies are used to treat metastatic CRC. Angiogenesis inhibitors, which inhibit the blood supply to tumors, include bevacizumab (Avastin) and ziv-aflibercept (Zaltrap). Regorafenib (Stivarga) is a multi-kinase inhibitor that blocks several enzymes that promote cancer growth. Cetuximab (Erbitux) and panitumumab (Vectibix) block the epidermal growth factor receptor.

Bevacizumab can also be used in combination with chemotherapy (e.g., fluoropyrimidine-oxaliplatin or fluoropyrimidine-irinotecan) to treat metastatic CRC. (Chemotherapy and targeted therapy are discussed in more detail in Chapter 16.)

Radiation Therapy. Radiation therapy may be used postoperatively as an adjuvant to surgery and chemotherapy or as a palliative measure for patients with metastatic cancer. As a palliative measure, its primary objective is to reduce tumor size and provide symptomatic relief. (Radiation therapy is described in Chapter 16.)

TABLE 43-25 NURSING ASSESSMENT

Colorectal Cancer

Subjective Data

Important Health Information

Past health history: Previous breast or ovarian cancer, familial polyposis, villous adenoma, adenomatous polyps, inflammatory bowel disease

Medications: Use of any medications affecting bowel function (e.g., laxatives, antidiarrheal drugs)

Functional Health Patterns

Health perception–health management: Family history of colorectal, breast, or ovarian cancer; weakness, fatigue

Nutritional-metabolic: High-calorie, high-fat, low-fiber diet; anorexia, weight loss; nausea and vomiting

Elimination: Change in bowel habits; alternating diarrhea and constipation, defecation urgency; rectal bleeding; mucoid stools; black, tarry stools; increased flatus, decrease in stool caliber; feelings of incomplete evacuation

Cognitive-perceptual: Abdominal and low back pain, tenesmus

Objective Data

General

Pallor, cachexia, lymphadenopathy (later signs)

Gastrointestinal

Palpable abdominal mass, distention, ascites, and hepatomegaly (liver metastasis)

Possible Diagnostic Findings

Anemia; guaiac-positive stools, palpable mass on digital rectal examination; positive sigmoidoscopy, colonoscopy, barium enema, or CT scan; positive biopsy

NURSING MANAGEMENT COLORECTAL CANCER

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with CRC are presented in Table 43-25.

NURSING DIAGNOSES

Nursing diagnoses for the patient with CRC include, but are not limited to, the following:

- Diarrhea or constipation *related to* altered bowel elimination patterns
- Fear and anxiety *related to* diagnosis of CRC, surgical or therapeutic interventions, and possible terminal illness
- Ineffective coping *related to* diagnosis of cancer and side effects of treatment

PLANNING

The overall goals are that the patient with CRC will have (1) normal bowel elimination patterns, (2) quality of life appropriate to disease progression, (3) relief of pain, and (4) feelings of comfort and well-being.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Encourage all persons over 50 to have regular CRC screening. Help identify those at high risk who need screening at an earlier age. Participate in early cancer screening to help decrease mortality rates. Realize that barriers exist, including lack of information and fear of diagnosis.

Endoscopic and radiographic procedures can only reveal polyps when the bowel has been adequately prepared to eliminate stool. Provide teaching about bowel cleansing for outpatient diagnostic procedures, and administer cleansing preparations to inpatients. Generally, the patient is placed on a clear liquid diet for 24 to 48 hours before the procedure and is given 4 L of oral polyethylene glycol (PEG) lavage solution the evening before the procedure. Drinking 2 L the evening before and 2 L the morning of the procedure provides better cleansing, especially for endoscopy scheduled for the afternoon. Because many people find the PEG lavage solution difficult to drink and experience nausea and bloating, manufacturers have modified the PEG solutions to improve taste and palatability. Magnesium citrate solution or bisacodyl tablets are sometimes given before the PEG lavage to remove the bulk of stool so only 2 L of PEG are needed. Encourage the patient to drink all of the solution. Stools will be clear or clear yellow liquid when the colon is clean.

ACUTE INTERVENTION. Acute nursing care for the patient with a colon resection is similar to care of the patient having a laparotomy (see pp. 970-971). If the cancer was resected and the ends reanastomosed, bowel function is maintained and routine postoperative care is appropriate. Inform patients about prognosis and future screening. Provide support for dealing with the diagnosis of cancer. Patients who have an APR will have a permanent ostomy and need emotional support to cope with their prognosis and the radical change in body appearance and function.

Patients with more extensive surgery (e.g., APR) may have an open wound and drains (e.g., Jackson-Pratt, Hemovac) and a permanent stoma. Postoperative care includes sterile dressing changes, care of drains, and patient and caregiver teaching about the stoma. Consult with a wound, ostomy, and continence (WOC) nurse before surgery to select the ostomy site on the abdomen, and then provide follow-up care and teaching.

A patient who has open and packed wounds requires meticulous postoperative care. Reinforce dressings and change them frequently during the first several hours postoperatively when drainage is likely to be profuse. Carefully assess all drainage for amount, color, and consistency. The drainage is usually serosanguineous. Examine the wound regularly and record bleeding, excessive drainage, and unusual odor. Use aseptic technique with dressing changes.

If the patient's wound is closed or partially closed, assess the incision for suture integrity and signs and symptoms of wound inflammation and infection. Examine the drainage for amount, color, and characteristics. Observe the skin around the drain for signs of inflammation, and keep the area around the drain clean and dry. Monitor for edema, erythema, and drainage around the suture line, as well as fever and an elevated WBC count.

The patient may experience phantom rectal sensation because the sympathetic nerves responsible for rectal control are not severed during the surgery. Be astute in distinguishing phantom sensations from perineal abscess pain.

Sexual dysfunction is a possible complication of an APR. Although the likelihood of sexual dysfunction depends on the surgical technique used, the surgeon should discuss the possibility with the patient. Members of the health care team should be available to address the patient's questions and concerns. Erection, ejaculation, and orgasm involve different nerve pathways, and a dysfunction of one does not mean complete sexual dysfunction. The WOC nurse is an important

source of information concerning sexual dysfunction resulting from an APR.

AMBULATORY AND HOME CARE. Psychologic support for the patient and caregiver is important. The cancer could return. Patients need much emotional support because recurrent cancer is painful, debilitating, and demoralizing. (The special needs of the cancer patient are discussed in Chapter 16.) Issues surrounding palliative care, end-of-life preparation, and hospice need to be addressed (see Chapter 10).

Patients with colostomies need to know how to care for them. Even when patients do not have stomas, they may experience diarrhea, constipation, incontinence, or difficulty passing stool depending on the section of the colon removed and the surgical procedure performed. Patients need to know about diet; incontinence products; and strategies for managing bloating, diarrhea, and bowel evacuation. Often a combination of dietary changes and drugs is used to control diarrhea and constipation.

Patients with sphincter-sparing surgery frequently experience diarrhea and incontinence of feces and gas. They often need antidiarrheal drugs or bulking agents to control the diarrhea, but may overuse them and become constipated. Consultation with a dietitian would help patients and caregivers understand how to choose foods that are less likely to cause diarrhea and odor and could help them discover which foods are problematic for them.

EVALUATION

The expected outcomes for the patient with CRC are that the patient will have

- Minimal alterations in bowel elimination patterns
- Balanced nutritional intake
- Quality of life appropriate to disease progression
- Feelings of comfort and well-being

OSTOMY SURGERY

Types

An **ostomy** is a surgical procedure that allows intestinal contents to pass from the bowel through an opening in the skin on the abdomen. The opening is called a **stoma.** The stoma is created when the intestine is brought through the abdominal wall and sutured to the skin. The intestinal contents then empty through the hole on the surface of the abdomen rather than being eliminated through the anus.

An ostomy is used when the normal elimination route is no longer possible. For example, if the person has CRC, the diseased portion is removed together with a certain margin of healthy tissue. Most stage I to III tumors of the colon can be resected, leaving enough healthy tissue to immediately *anastomose* the two remaining ends of healthy bowel, and no ostomy is necessary. If the tumor involves the rectum and is large enough to necessitate the removal of the anal sphincters, the

TABLE 43-26 COMPARISON OF ILEOSTOMY AND COLOSTOMY

		Colostomy		
Characteristic	**Ileostomy**	**Ascending**	**Transverse**	**Sigmoid**
Stool consistency	Liquid to semiliquid	Semiliquid	Semiliquid to semiformed	Formed
Fluid requirement	Increased	Increased	Possibly increased	No change
Bowel regulation	No	No	No	Yes (if there is a history of a regular bowel pattern)
Pouch and skin barriers	Yes	Yes	Yes	Dependent on regulation
Irrigation	No	No	No	Possibly every 24-48 hr (if patient meets criteria)
Indications for surgery	Ulcerative colitis, Crohn's disease, diseased or injured colon, familial polyposis, trauma, cancer	Perforating diverticulum in lower colon, trauma, rectovaginal fistula, inoperable tumors of colon, rectum, or pelvis	Same as for ascending	Cancer of the rectum or rectosigmoidal area, perforating diverticulum, trauma

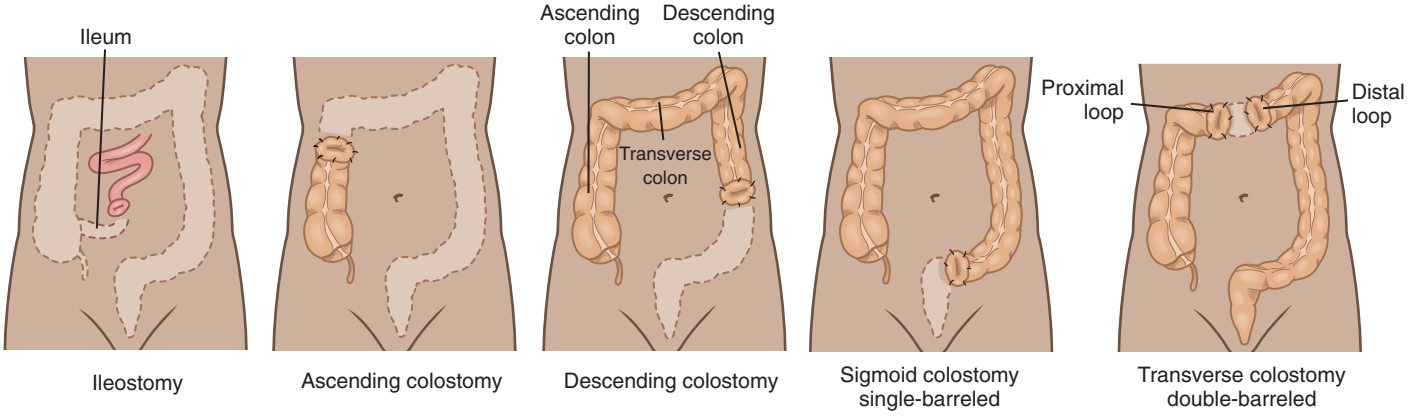

FIG. 43-9 Types of ostomies.

anus is sutured shut and a permanent ostomy is created. Patients at high risk for CRC, such as those with FAP, and patients with ulcerative colitis may have a total colectomy.

Ostomies are described according to location and type (Fig. 43-9). An ostomy in the ileum is called an *ileostomy*. An ostomy in the colon is called a *colostomy*. The ostomy is further characterized by its anatomic site (e.g., sigmoid or transverse colostomy). The more distal the ostomy, the more the intestinal contents resemble feces that are eliminated from an intact colon and rectum. Output from an ileostomy has not entered the colon and thus is liquid. The ileostomy drains continuously, and the patient must constantly wear a bag to collect the drainage. In contrast, output from a sigmoid colostomy resembles normal formed stool, and some patients are able to regulate emptying time so they do not need to wear a collection bag. (See Colostomy Irrigations later in this chapter.) A comparison of colostomies and ileostomies is shown in Table 43-26.

Ostomies may be temporary or permanent. For example, the person with a draining fistula may need a temporary ostomy to prevent stool from reaching the diseased area. Patients who have trauma to the intestines (e.g., gunshot wound, stabbing) may need a temporary ostomy. Cancer involving the rectum requires a permanent ostomy because all bowel distal to the ostomy is removed.

The major types of ostomies are end stoma, double-barreled, and loop ostomy.

End Stoma. An end stoma is surgically constructed by dividing the bowel and bringing out the proximal end as a single stoma. The distal portion of the GI tract is surgically removed, or the distal segment is oversewn and left in the abdominal cavity with its mesentery intact. An end colostomy or ileostomy is then constructed. When the distal bowel is oversewn rather than removed, the procedure is known as a Hartmann's pouch (Fig. 43-10). In this procedure the potential exists for the bowel to be reanastomosed and the stoma to be closed (referred to as a *takedown*). If the distal bowel is removed, the stoma is permanent.

Loop Stoma. A loop stoma is constructed by bringing a loop of bowel to the abdominal surface and then opening the anterior wall of the bowel to provide fecal diversion. This results in one stoma with a proximal opening for feces and a distal opening for mucus drainage (from the distal colon). An intact posterior wall separates the two openings. The loop of bowel is frequently held in place with a plastic rod for 7 to 10 days after surgery to prevent it from slipping back into the abdominal cavity (Fig. 43-11). A loop stoma is usually temporary.

Double-Barreled Stoma. When the bowel is divided, both the proximal and distal ends are brought through the abdominal wall as two separate stomas (see Fig. 43-9). The proximal one is the functioning stoma. The distal, nonfunctioning stoma is referred to as the mucus fistula. The double-barreled stoma is usually temporary.

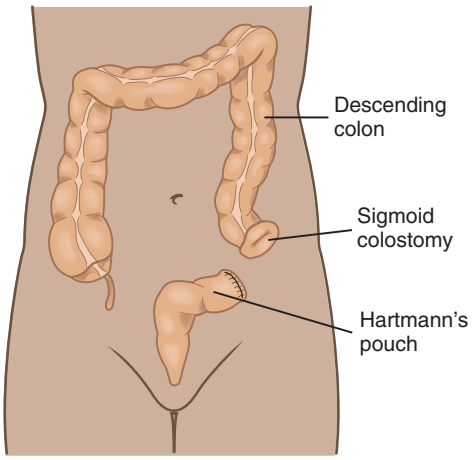

FIG. 43-10 Sigmoid colostomy. Distal bowel is oversewn and left in place to create Hartmann's pouch.

NURSING MANAGEMENT OSTOMY SURGERY

Two major aspects of nursing care are (1) emotional support as the patient copes with a radical change in body image and (2) patient and caregiver teaching about stoma care and the ostomy.[39] People with ostomies lose control over flatus and feces and worry about odor and leakage of feces from around the bag.[40] With time people learn to manage the stoma and make adjustments in work, social interactions, and sexual activities. People with new ostomies may be reluctant to return to work and avoid being around other people. Initially, patients may feel unattractive to their partners and unwilling to engage in sexual activities. However, with emotional support and teaching, patients can learn to manage the ostomy and return to their previous lifestyle.

PREOPERATIVE CARE

Major aspects of preoperative care that are unique to ostomy surgery include (1) psychologic preparation for the ostomy, (2) selection of a flat site on the abdomen that allows secure attachment of the collection bag, and (3) selection of a stoma site that will be clearly visible to the patient who will be taking care of it and is appropriate for clothing habits and activities.[41] Psychologic preparation and emotional support are particularly important as the person copes with the change in body image, the loss of control over elimination, and the odors. Provide the patient opportunities for verbalization of concerns and questions. This will enhance the patient's feelings of control and thus ability to cope.

A WOC nurse should select the site where the ostomy will be positioned and mark the abdomen preoperatively.[41-43] The site should be within the rectus muscle on a flat surface that the patient is able to see. Stomas placed outside the rectus muscle increase the chance of developing a hernia. A flat site makes it much easier to create a good seal and avoid leakage from

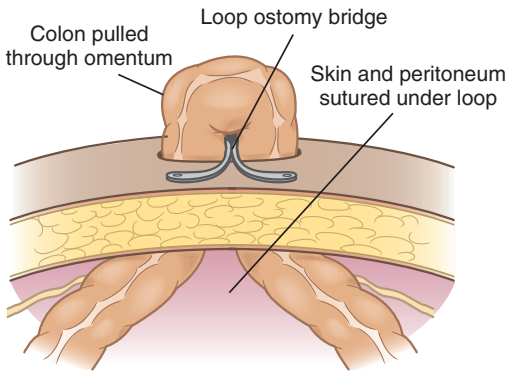

FIG. 43-11 Loop colostomy.

the bag. Patients who cannot see the stoma are unable to care for it.

The patient and caregiver usually have many questions concerning the procedures. If available, a WOC nurse should visit with the patient and the caregiver to determine the patient's ability to perform self-care, identify support systems, and determine any modifications that could facilitate learning during rehabilitation. The patient and the caregiver should understand the extent of surgery, the type of stoma, and related care.

Ask the patient if he or she would like to meet with a person who has adjusted to an ostomy. This gives the patient and caregiver an opportunity to question a person who has adjusted well to an ostomy and who has experienced some of the same feelings and concerns that they have.

POSTOPERATIVE CARE

Postoperative nursing care includes assessment of the stoma and provision of an appropriate pouching system that protects the skin and contains drainage and odor. The stoma should be dark pink to red. A dusky blue stoma indicates ischemia, and a brown-black stoma indicates necrosis. Assess and document stoma color every 4 hours and ensure that there is no excessive bleeding. Teach the patient that the stoma is mildly to moderately swollen the first 2 to 3 weeks after surgery (Table 43-27). A smaller pouch opening will be needed as the swelling goes down to accommodate the stoma's changing size. Determine the size of the stoma with a stoma-measuring card.

The colostomy starts functioning when peristalsis returns. When a temporary colostomy is performed on a colon that was not cleaned out before surgery, stool will drain when peristalsis returns. However, if the bowel was cleansed preoperatively, it will not begin producing stool until days after the surgery when the patient is eating again.

An appropriate pouching system is vital to protect the skin and provide dependable drainage collection. The various pouching systems all have an adhesive skin barrier and a bag or pouch to collect the feces. Flatus is expelled from the bag through a charcoal filter that helps control odor. The skin barrier is a piece of pectin-based or karaya wafer that has a measurable thickness and hydrocolloid adhesive properties. The adhesion occurs in two phases. First, the wafer's backing has adhesive material that forms an immediate bond with the skin. Second, the hydrocolloids interface with the moisture on the skin to form a tighter seal. If the abdominal stoma site has bends or creases, it is difficult to get a good seal and the skin barrier will pull away faster. Also, the weight of drainage from the stoma pulls the wafer away from the skin. For this reason, ostomy bags should be emptied when one-third full.

In the postoperative period an open-ended, transparent, plastic, odor-proof pouch is used to observe the stoma and collect the drainage. Record the volume, color, and consistency of the drainage. Each time the pouch is changed, observe the condition of the skin for irritation. Never place a pouch directly on irritated skin without the use of a skin barrier.

Teach the patient to perform a pouch change, provide appropriate skin care, control odor, care for the stoma, and identify signs and symptoms of complications. Instruct the patient about the importance of fluids and a healthy diet. Provide the names and addresses of United Ostomy Associations of America, and instruct the patient on when to seek health care. Home care and outpatient follow-up by a WOC nurse are highly recommended. Patients should be discharged with written information about their particular ostomy, instructions for pouch changes, a list of supplies and where to purchase them (including names and phone numbers of retailers), outpatient follow-up appointments with the surgeon and WOC nurse, and phone numbers of the surgeon and nurse. Patient and caregiver teaching guidelines are presented in Table 43-28.

Teaching is often complicated by the emotional responses to the stoma. Emotional support, interventions from skillful WOC nurses, and visits from people who have successfully learned to manage their ostomies will help patients learn to cope with and manage the new stoma.

TABLE 43-27 CHARACTERISTICS OF STOMA

Characteristic	Description or Cause
Color*	
Rose to brick-red	Viable stoma mucosa.
Pale	May indicate anemia.
Blanching, dark red to purple	Indicates inadequate blood supply to the stoma or bowel.
Edema†	
Mild to moderate edema	Normal in the initial postoperative period. Trauma to the stoma.
Moderate to severe edema	Obstruction of the stoma, allergic reaction to food, gastroenteritis.
Bleeding	
Small amount	Oozing from the stoma mucosa when touched is normal because of its high vascularity.
Moderate to large amount	Could indicate lower gastrointestinal bleeding, coagulation factor deficiency, stomal varices secondary to portal hypertension.

*Report sustained color changes to surgeon.
†Closely observe and report to the surgeon and adjust the stoma opening size in the pouch.

COLOSTOMY CARE

Nursing care for the patient with a colostomy is presented in eNursing Care Plan 43-3 on the website. A colostomy in the ascending and transverse colon has semiliquid stools. Instruct the patient to use a drainable pouch. A colostomy in the sigmoid or descending colon has semiformed or formed stools and can sometimes be regulated by the irrigation method. For these patients, a drainage pouch may or may not be needed. Gas filters are available for both drainable and nondrainable pouches.

A well-balanced diet and adequate fluid intake are important, and most patients with colostomies can eat anything they choose. However, dietary modifications are helpful for decreasing gas production and odor. eTable 43-4 (on the website for this chapter) lists foods and their effects on stoma output.

Colostomy Irrigations. Colostomy irrigations may be used to stimulate emptying of the colon. When the colon is irrigated and emptied on a regular basis, no stool is eliminated between irrigation sessions. Irrigation requires manual dexterity and adequate vision. However, if bowel control is achieved, little or no spillage should occur between irrigations, and the patient may need to wear only a pad or small pouch over the stoma. Regularity is possible only when the stoma is in the distal colon. Irrigation is not used for more proximal ostomies. People who irrigate regularly should still have ostomy bags readily available in case they develop diarrhea from foods or illness. The proce-

TABLE 43-28 PATIENT & CAREGIVER TEACHING GUIDE

Ostomy Self-Care

Include the following instructions when teaching the patient and/or caregiver about self-care of an ostomy.

1. Explain what an ostomy is and how it functions.
2. Describe the underlying condition that resulted in the need for an ostomy.
3. Demonstrate and allow the patient and caregiver to practice the following activities:
   - Remove the old skin barrier, cleanse the skin, and correctly apply new skin barriers.
   - Apply, empty, clean, and remove the pouch.
   - Empty the pouch before it is one-third full to prevent leakage.
   - Irrigate the colostomy to regulate bowel elimination (optional).
4. Explain how to contact the wound, ostomy, and continence (WOC) nurse with questions.
5. Describe how to obtain additional ostomy supplies.
6. Explain dietary and fluid management.
   - Identify a well-balanced diet and dietary supplements to prevent nutritional deficiencies.
   - Identify foods to avoid to reduce diarrhea, gas, or obstruction (with ileostomy).
   - Promote fluid intake of least 3000 mL/day to prevent dehydration (unless contraindicated).
   - Increase fluid intake during hot weather, excessive perspiration, and diarrhea to replace losses and prevent dehydration.
   - Describe symptoms of fluid and electrolyte imbalance.
   - Explain how to contact the registered dietitian with questions.
   - Explain how to recognize problems (fluid and electrolyte deficits, fever, diarrhea, skin irritation, stomal problems) and how to contact the appropriate health care provider.
7. Describe community resources to assist with emotional and psychologic adjustment to the ostomy.
8. Explain the importance of follow-up care.
9. Describe the ostomy's potential effects on sexual activity, social life, work, and recreation and strategies to manage these changes.

TABLE 43-29 PATIENT & CAREGIVER TEACHING GUIDE

Colostomy Irrigation

Include the following instructions when teaching the patient and caregiver to perform a colostomy irrigation.

Equipment*

Lubricant
Irrigation set (1000- to 2000-mL container, tubing with irrigating stoma cone, clamp)
Irrigating sleeve with adhesive or belt
Toilet tissue to clean around the stoma
Disposal sack for soiled dressing

Procedure

1. Place 500-1000 mL of lukewarm water (not to exceed 105° F [40.5° C]) in container. Titrate the volume for the individual; use enough irrigant to distend the bowel but not enough to cause cramping pain. Most adults use 500-1000 mL of water.
2. Ensure a comfortable position. Patient may sit in chair in front of toilet or on the toilet if the perineal wound is healed.
3. Clear tubing of all air by flushing it with fluid.
4. Hang container on hook or IV pole (18-24 in) above stoma (about shoulder height).
5. Apply irrigating sleeve and place bottom end in toilet bowl.
6. Lubricate stoma cone, insert cone tip gently into the stoma, and hold tip securely in place. The cone is designed to prevent perforation, control the depth of insertion, and prevent water from coming out of the stoma.
7. Allow irrigation solution to flow in steadily for 5-10 min.
8. If cramping occurs, stop the flow of solution for a few seconds, leaving the cone in place.
9. Clamp the tubing and remove irrigating cone when the desired amount of irrigant has been delivered or when the patient senses colonic distention.
10. Allow 30-45 min for the solution and feces to be expelled. Initial evacuation is usually complete in 10-15 min. Close off the irrigating sleeve at the bottom to allow ambulation.
11. Clean, rinse, and dry peristomal skin well.
12. Replace the colostomy drainage pouch or desired stoma covering.
13. Wash and rinse all equipment and hang to dry.

*Commercial sets usually have all the equipment that you will need.

dure for colostomy irrigation is similar to an enema and is presented in Table 43-29.

ILEOSTOMY CARE

An ileostomy stoma protrusion of at least 1 to 1.5 cm makes care easier. When the stoma is flat, seepage occurs, resulting in altered skin integrity. Drainage is frequent and extremely irritating to the skin. Since regularity cannot be established with an ileostomy, a pouch must be worn at all times. An open-ended, drainable pouch is preferable so drainage can be easily emptied. The drainable pouch is usually worn for 4 to 7 days before being changed, unless leakage occurs. In that case, the pouch should be promptly removed, the skin cleansed, and a new pouch applied. A solid skin barrier should always be used.

A transparent pouch should be used in the initial postoperative period to facilitate assessment of stoma viability and pouch application by the patient. Later on patients may prefer opaque pouches. (eNursing Care Plan 43-3 [on the website for this chapter] presents care of the patient with an ileostomy.)

Observe the patient with an ileostomy for signs and symptoms of fluid and electrolyte imbalance, particularly potassium, sodium, and fluid deficits. In the first 24 to 48 hours after surgery the amount of drainage from the stoma may be negligible. Patients with new ileostomies lose the absorptive functions provided by the colon and the delay provided by the ileocecal valve. As a result, they may experience a period of high-volume output of 1000 to 1800 mL/day when peristalsis returns. Later, as the proximal small bowel adapts, the average amount can be 500 mL/day. If the small bowel has been shortened by surgery, drainage from the ileostomy may be greater. Patients need to increase fluid intake to at least 2 to 3 L/day, or more when there are excessive fluid losses from heat and sweating. They may also need to ingest additional sodium. Patients must learn signs and symptoms of fluid and electrolyte imbalance so that they can take appropriate action.

A low-fiber diet is ordered initially, and fiber-containing foods are reintroduced gradually. The ileostomy patient is susceptible to obstruction because the lumen is less than 1 in in diameter and may narrow further at the point where the bowel passes through the fascia/muscle layer of the abdomen. Foods such as popcorn, coconut, mushrooms, olives, stringy vegetables, foods with skins, dried fruits, and meats with casings must be chewed extremely well before swallowing. The goal is for the patient to return to a normal, presurgical diet. If the terminal ileum has been removed, the patient may need cobalamin treatment.

DELEGATION DECISIONS

Ostomy Care

Although licensed practical/vocational nurses (LPN/LVNs) and unlicensed assistive personnel (UAP) provide much of the ostomy care for patients with established ostomies, patients with new ostomies have complex needs and require frequent assessment, planning, intervention, and evaluation by a registered nurse (RN).

Role of Registered Nurse (RN)

- Assess and document stoma appearance.
- For patient with a new ostomy, assess patient's psychologic preparation for ostomy care.
- Choose appropriate ostomy pouching system (skin barrier and bag or pouch) for patient.
- Place ostomy pouching system for a new ostomy.
- Develop plan of care for skin care around the ostomy.
- Teach ostomy care and skin care to patient and caregiver.
- Irrigate new colostomy.
- Teach colostomy irrigation to patient and caregiver.
- Teach patient and caregivers about appropriate dietary choices.
- Consult with wound, ostomy, and continence (WOC) nurse.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Monitor the volume, color, and odor of the ostomy drainage.
- Monitor the skin around the ostomy for breakdown.
- Provide skin care around the ostomy.
- Irrigate colostomy in stable patient.

Role of Unlicensed Assistive Personnel (UAP)

- Empty ostomy bag and measure liquid contents.
- Place the ostomy pouching system for an established ostomy.
- Assist stable patient with colostomy irrigation.

The stoma bleeds easily when it is touched because it has a high vascular supply. Tell the patient that minimal oozing of blood is normal.

ADAPTATION TO AN OSTOMY

Patients experience a grief reaction from the loss of a body part and an alteration in body image. They may feel like they are no longer normal and may experience shame and social isolation. People commonly feel anxiety and fear about stool leaking and the smells and sounds of flatus and stool entering the pouch. They are concerned about how the stoma will affect their lifestyle, including work, eating, sports, sex, and sleeping. They may be angry, depressed, or resentful.

Discuss the psychologic impact of the stoma and how it affects the patient's body image and self-esteem. Assist the patient in identifying ways of coping with depression and anxiety resulting from illness, surgery, or postoperative problems.[44]

Support from the caregiver, family, and friends is vitally important and reassures the patient that he or she is cherished and valued despite having the ostomy. Encourage patients to share their concerns and ask questions, provide information in a manner that is easily understood, recommend support services, and help patients develop confidence and competence in managing the stoma.

The patient can resume activities of daily living within 6 to 8 weeks but should avoid heavy lifting. The patient's physical condition determines when sports may be resumed. Some health care providers recommend avoiding participation in sports where direct trauma to the stoma is likely. Bathing and swimming may be done with or without the pouching system in place because water does not harm the stoma.

Patients want to know how to manage gas and body odors and how to choose clothing that will hide the stoma. Refer patients to the United Ostomy Associations of America *(www.ostomy.org)* for (1) practical information about living with an ostomy (e.g., ostomy products, irrigation, travel, sex), (2) contact information for local support groups, and (3) opportunities for online communication with other people with ostomies.

SEXUAL FUNCTION AFTER OSTOMY SURGERY

The patient with a stoma may fear rejection by a partner or that others will not find him or her desirable. Incorporate a discussion of sexuality and sexual function in the plan of care. Help the patient understand that sexual function or sexual activity may be affected, but sexuality does not have to be altered. Help the patient realize that it takes time to adjust to the pouch and to body changes before feeling secure in his or her sexual functioning. Also, a woman with an ostomy can still become pregnant.

Pelvic surgery can disrupt nerve and vascular supplies to the genitalia. Radiation therapy, chemotherapy, and medications can also alter sexual function. The patient's overall physical health influences sexual desire. Generalized fatigue caused by illness can also influence desire. Understanding this information can help patients better plan the timing of their sexual activity.

Erection of the penis depends on intact parasympathetic nerves and adequate blood supply to the pelvis and to pudendal nerves that transmit sensory responses from the genital area. Nerve-sparing surgical techniques are used when possible to preserve sexual function. Unfortunately, any pelvic surgery that removes the rectum has the potential of damaging the parasympathetic nerve plexus. Pelvic radiation can reduce blood flow to the pelvis by causing scarring in the small blood vessels. Muscle contraction and genital pleasure that occur during orgasm are not disrupted by pelvic surgery. If the sympathetic nerves in the male's presacral area are damaged, ejaculation may be disrupted. This can occur with the APR procedure.

DIVERTICULOSIS AND DIVERTICULITIS

Diverticula are saccular dilations or outpouchings of the mucosa that develop in the colon (Fig. 43-12). Multiple noninflamed diverticula are present in diverticulosis (see eFig. 43-3 on the website for this chapter). *Diverticulitis* is inflammation of the diverticula, resulting in perforation into the peritoneum. Clinically, diverticular disease covers a spectrum from asymptomatic, uncomplicated diverticulosis to diverticulitis with complications such as perforation, abscess, fistula, and bleeding.

Etiology and Pathophysiology

Diverticula are common, especially in older adults, but most people never develop diverticulitis.[45] Diverticula may occur anywhere in the GI tract but are most commonly found in the left (descending, sigmoid) colon. The etiology of diverticulosis of the sigmoid colon is thought to be associated with high luminal pressures from a deficiency in dietary fiber intake. The disease is more prevalent in Western, industrialized populations that consume diets low in fiber and high in refined carbohydrates. Diverticula are uncommon in vegetarians. Inadequate dietary fiber slows transit time, and more water is absorbed

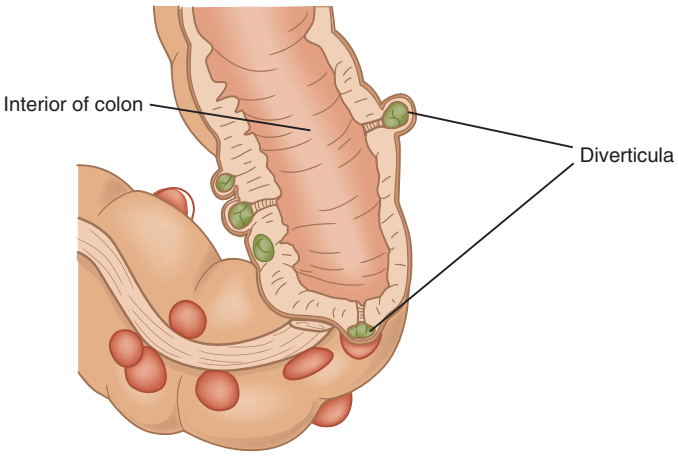

FIG. 43-12 Diverticula are outpouchings of the colon. When they become inflamed, the condition is diverticulitis. The inflammatory process can spread to the surrounding area in the intestine.

from the stool, making it more difficult to pass through the lumen. Decreased stool size raises intraluminal pressure, thus promoting diverticula formation.

Clinical Manifestations and Complications

The majority of patients with diverticulosis have no symptoms. Those with symptoms typically have abdominal pain, bloating, flatulence, or changes in bowel habits. In more serious situations, the diverticula bleed or diverticulitis develops. Diverticulitis is characterized by inflamed diverticula and increased luminal pressures that cause erosion of the bowel wall, and thus perforation into the peritoneum (Fig. 43-13). The most common symptoms of diverticulitis are acute pain in the left lower quadrant (location of sigmoid colon), a palpable abdominal mass, and systemic symptoms of infection (fever, increased C-reactive protein, and leukocytosis with a shift to the left).[45] Older adults with diverticulitis may be afebrile, with a normal WBC count and little, if any, abdominal tenderness. A localized abscess develops when the body is able to wall off the area of perforation. Peritonitis develops if it cannot be contained. Bleeding can be extensive, but usually stops spontaneously.

PATHOPHYSIOLOGY MAP

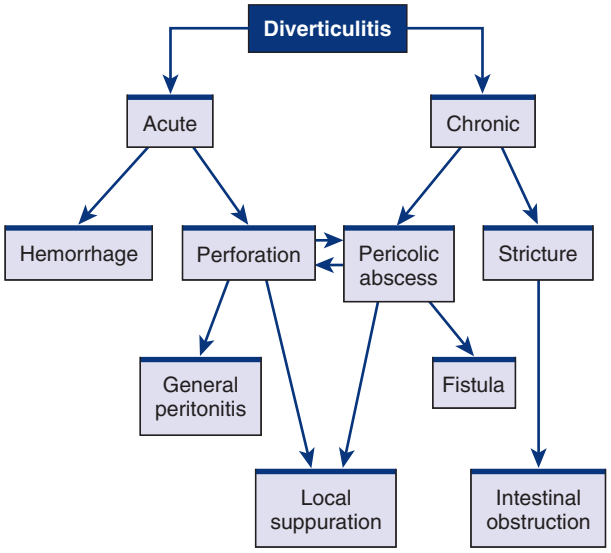

FIG. 43-13 Complications of diverticulitis.

TABLE 43-30 COLLABORATIVE CARE

Diverticulosis and Diverticulitis

Diagnostic

- History and physical examination
- Testing of stool for occult blood
- Barium enema
- Sigmoidoscopy
- Colonoscopy
- CBC
- Urinalysis
- Blood culture
- CT scan with oral contrast
- Abdominal x-ray
- Chest x-ray

Collaborative Therapy

Conservative Therapy

- High-fiber diet
- Dietary fiber supplements
- Stool softeners
- Anticholinergics
- Bed rest
- Clear liquid diet
- Oral antibiotics
- Mineral oil
- Bulk laxatives
- Weight reduction (if overweight)

Acute Care: Diverticulitis

- Antibiotic therapy
- NPO status
- IV fluids
- Bed rest
- NG suction
- Surgery
  - Possible resection of involved colon for obstruction or hemorrhage
  - Possible temporary colostomy

Diagnostic Studies

Diverticular disease can be asymptomatic and is typically discovered during routine sigmoidoscopy or colonoscopy. Diagnosis of diverticulitis is based on the history and physical examination (Table 43-30). Abdominal and chest x-ray rule out other causes of acute abdominal pain, but the preferred diagnostic test is a CT scan with oral contrast.

NURSING AND COLLABORATIVE MANAGEMENT DIVERTICULOSIS AND DIVERTICULITIS

A high-fiber diet, mainly from fruits and vegetables, and decreased intake of fat and red meat are recommended for preventing diverticular disease. High levels of physical activity also seem to decrease the risk. A high-fiber diet (see Table 43-6) is also recommended once diverticular disease is present. Currently there is no evidence to support the theory that diverticulitis can be prevented by avoiding nuts and seeds.

Weight reduction is important for the obese person. A patient with diverticular disease should avoid increased intraabdominal pressure because it may precipitate an attack. Factors that increase intraabdominal pressure are straining at stool, vomiting, bending, lifting, and wearing tight restrictive clothing.

In acute diverticulitis the goal of treatment is to let the colon rest and the inflammation subside. Some patients can be managed at home with oral antibiotics and a clear liquid diet. Hospitalization is necessary if symptoms are severe, the patient is unable to tolerate oral fluids, or the patient has co-morbid diseases.

Patients who are older, are immunosuppressed, or have systemic manifestations of infection (fever, significant leukocytosis) are hospitalized. If hospitalized, the patient is kept on NPO status and bed rest, and fluids and IV antibiotics are given. Observe for signs of abscess, bleeding, and peritonitis, and monitor the WBC count. When the acute attack subsides, give oral fluids first and then progress the diet to semisolids. Ambulation is allowed.

Surgery is reserved for patients with complications such as an abscess or obstruction that cannot be managed medically. The usual surgical procedures involve resection of the involved colon with either a primary anastomosis if adequate bowel cleansing is feasible or a temporary diverting colostomy. The colostomy is reanastomosed after the colon heals.

Provide the patient with diverticular disease with a full explanation of the condition. Patients who understand the disease process well and adhere to the prescribed regimen are less likely to experience an exacerbation of the disease and its complications.

HERNIAS

A **hernia** is a protrusion of the viscus (internal organ such as the intestine) through an abnormal opening or a weakened area in the wall of the cavity in which it is normally contained. A hernia may occur in any part of the body, but it usually occurs within the abdominal cavity (Fig. 43-14). Hernias that easily return to the abdominal cavity are called *reducible*. The hernia can be reduced manually or may reduce spontaneously when the person lies down. If the hernia cannot be placed back into the abdominal cavity, it is known as *irreducible* or *incarcerated*. In this situation the intestinal flow may be obstructed. When the hernia is irreducible and the intestinal flow and blood supply are obstructed, the hernia is strangulated. The result is an acute intestinal obstruction.

Types

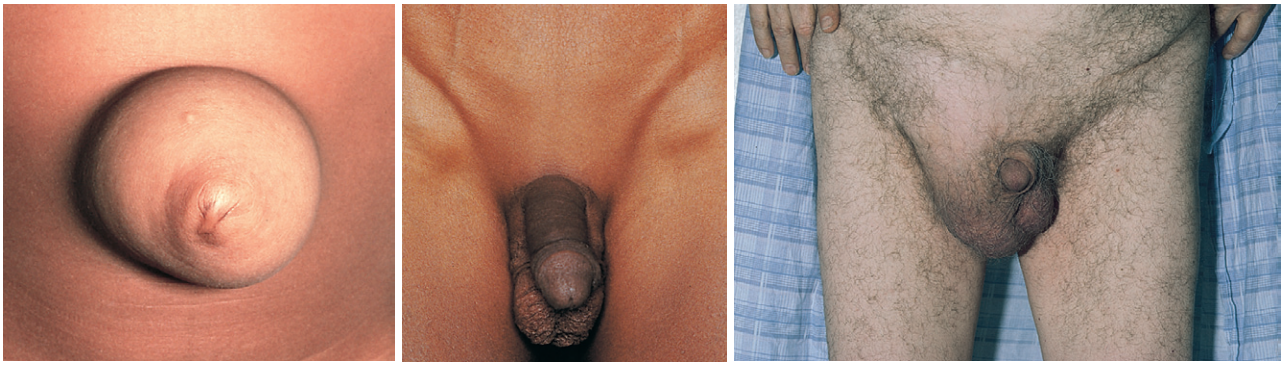
The *inguinal hernia* is the most common type of hernia and occurs at the point of weakness in the abdominal wall where the spermatic cord (in men) or the round ligament (in women) emerges (see Fig. 43-14, *C*). Inguinal hernias are more common in men.

A *femoral hernia* occurs when there is a protrusion through the femoral ring into the femoral canal. It appears as a bulge below the inguinal ligament. It easily becomes strangulated. It occurs more often in women (see Fig. 43-14, *B*). The *umbilical hernia* occurs when the rectus muscle is weak (as with obesity) or the umbilical opening fails to close after birth (see Fig. 43-14, *A*).

Ventral or *incisional hernias* are due to weakness of the abdominal wall at the site of a previous incision. They occur most commonly in patients who are obese, have had multiple surgical procedures in the same area, or have had inadequate wound healing because of poor nutrition or infection.

GENDER DIFFERENCES

Hernia



Men	Women
• Inguinal hernia is more common in men than in women. • The lifetime risk of developing a groin hernia is approximately 25% in men.	• Femoral hernia is more common in women (particularly older women) than in men. • The lifetime risk of developing a groin hernia is <5% in women.

Clinical Manifestations

A hernia may be readily visible, especially when the person tenses the abdominal muscles. There may be some discomfort as a result of tension. If the hernia becomes strangulated, the patient will have severe pain and symptoms of a bowel obstruction such as vomiting, cramping abdominal pain, and distention. Strangulated hernias or painful, inflamed hernias that cannot be reduced require emergency surgery.[46]

NURSING AND COLLABORATIVE MANAGEMENT HERNIAS

Diagnosis is based on history and physical examination findings. Laparoscopic surgery is the treatment of choice for hernias. The surgical repair of a hernia, known as a *herniorrhaphy,* is usually an outpatient procedure. Reinforcement of the weakened area with wire, fascia, or mesh is known as a *hernioplasty.*

A B C

FIG. 43-14 **A,** Umbilical hernia. **B,** Femoral hernias (note swelling below the inguinal ligaments). **C,** Right inguinal hernia.

Strangulated hernias are treated immediately with resection of the involved area or a temporary colostomy so that necrosis and gangrene do not occur.

After a hernia repair, the patient may have difficulty voiding. Measure intake and output and observe for a distended bladder. Scrotal edema is a painful complication after an inguinal hernia repair. A scrotal support with application of an ice bag may help relieve pain and edema. Encourage deep breathing, but not coughing. Teach patients to splint the incision and keep their mouths open when coughing or sneezing are unavoidable. The patient may be restricted from heavy lifting for 6 to 8 weeks.

MALABSORPTION SYNDROME

Malabsorption results from impaired absorption of fats, carbohydrates, proteins, minerals, and vitamins. The stomach, small intestine, liver, and pancreas regulate normal digestion and absorption. Digestive enzymes ordinarily break down nutrients so that absorption can take place. If this process is interrupted at any point, malabsorption may occur. Several problems can cause malabsorption (Table 43-31). Lactose intolerance is the most common malabsorption disorder, followed by IBD, celiac disease, tropical sprue, and cystic fibrosis.

The most common signs of malabsorption are weight loss, diarrhea, and **steatorrhea** (bulky, foul-smelling, yellow-gray, greasy stools with putty-like consistency) (Table 43-32). Steatorrhea does not occur with lactose intolerance.

Tests used to determine the cause of malabsorption include qualitative examination of stool for fat (e.g., Sudan III stain), a 72-hour stool collection for quantitative measurement of fecal fat, serologic testing for celiac disease, and fecal elastase testing to determine if there is pancreatic insufficiency. Near-infrared reflectance analysis (NIRA) for fecal fat is available at some centers in the United States.

Other diagnostic studies include a CT scan and endoscopy to obtain a small bowel biopsy specimen. A small bowel barium enema may be performed to identify abnormal mucosal patterns. Capsule endoscopy can be used to assess the small intestine for alterations in mucosal integrity and inflammation. Tests for carbohydrate malabsorption include the D-xylose test and the lactose tolerance test. Laboratory studies that are frequently ordered include a CBC, measurement of prothrombin time (to see if vitamin K absorption is adequate), serum vitamin A and carotene levels, serum electrolytes, cholesterol, and calcium.

TABLE 43-31 CAUSES OF MALABSORPTION

Biochemical or Enzyme Deficiencies
- Lactase deficiency
- Biliary tract obstruction
- Pancreatic insufficiency
- Cystic fibrosis
- Chronic pancreatitis
- Zollinger-Ellison syndrome

Disturbed Lymphatic and Vascular Circulation
- Lymphoma
- Ischemia
- Lymphangiectasia
- Heart failure

Bacterial Proliferation
- Tropical sprue
- Parasitic infection

Small Intestinal Mucosal Disruption
- Celiac disease
- Whipple's disease
- Crohn's disease

Surface Area Loss
- Billroth II gastrectomy
- Short bowel syndrome
- Distal ileal resection, disease, or bypass

CELIAC DISEASE

Celiac disease is an autoimmune disease characterized by damage to the small intestinal mucosa from the ingestion of wheat, barley, and rye in genetically susceptible individuals.[47] It is a relatively common disease that occurs at all ages and has a wide variety of symptoms. *Celiac sprue* and *gluten-sensitive enteropathy* are other names for celiac disease.

Celiac disease is not the same disease as *tropical sprue,* a chronic disorder acquired in tropical areas that is characterized

TABLE 43-32 MANIFESTATIONS OF MALABSORPTION

Manifestations	Pathophysiology
Gastrointestinal	
Weight loss	Malabsorption of fat, carbohydrates, and protein leading to loss of calories. Marked reduction in caloric intake or increased use of calories.
Diarrhea	Impaired absorption of water, sodium, fatty acids, bile salts, and carbohydrates.
Flatulence	Bacterial fermentation of unabsorbed carbohydrates.
Steatorrhea	Undigested and unabsorbed fat.
Glossitis, cheilosis, stomatitis	Deficiency of iron, riboflavin, cobalamin, folic acid, and other vitamins.
Hematologic	
Anemia	Impaired absorption of iron, cobalamin, and folic acid.
Hemorrhagic tendency	Vitamin C deficiency. Vitamin K deficiency inhibiting production of clotting factors II, VII, IX, and X.
Musculoskeletal	
Bone pain	Osteoporosis from impaired calcium absorption. Osteomalacia secondary to hypocalcemia, hypophosphatemia, inadequate vitamin D.
Tetany	Hypocalcemia, hypomagnesemia.
Weakness, muscle cramps	Anemia, electrolyte depletion (especially potassium).
Muscle wasting	Protein malabsorption.
Neurologic	
Altered mental status	Dehydration.
Paresthesias	Cobalamin deficiency.
Peripheral neuropathy	Cobalamin deficiency.
Night blindness	Thiamine deficiency, vitamin A deficiency.
Integumentary	
Bruising	Vitamin K deficiency.
Dermatitis	Fatty acid deficiency, zinc deficiency, niacin and other vitamin deficiencies.
Brittle nails	Iron deficiency.
Hair thinning and loss	Protein deficiency.
Cardiovascular	
Hypotension	Dehydration.
Tachycardia	Hypovolemia, anemia.
Peripheral edema	Protein malabsorption, protein loss in diarrhea.

by progressive disruption of jejunal and ileal tissue, resulting in nutritional difficulties. Tropical sprue is treated with folic acid and tetracycline.

Celiac disease is most common in people of European ancestry and affects about 1% of the population of the United States. High-risk groups include first- or second-degree relatives of someone with celiac disease and people with disorders associated with the disease such as migraine and myocarditis. It is slightly more common in women, and symptoms often begin in childhood.

Etiology and Pathophysiology

Three factors necessary for developing celiac disease are genetic predisposition, gluten ingestion, and an immune-mediated response.

Genetic Link

About 90% to 95% of patients with celiac disease have human leukocyte antigen (HLA) alleles HLA-DQ2, and the other 5% to 10% have HLA-DQ8. However, not everyone with these genetic markers develops celiac disease, and some people with celiac disease do not have these HLA alleles. (HLAs are discussed in Chapter 14.)

As with other autoimmune diseases, the tissue destruction that occurs with celiac disease is the result of chronic inflammation. Inflammation is activated by the ingestion of gluten found in wheat, rye, and barley. Gluten contains specific peptides called prolamines. In genetically susceptible individuals, partial digestion of gluten releases prolamine peptides, which are absorbed into the intestinal submucosa. The peptides then bind to HLA-DQ2 and/or HLA-DQ8 and activate an inflammatory response. Inflammation damages the microvilli and brush border of the small intestine, ultimately decreasing the amount of surface area available for nutrient absorption. Damage is most severe in the duodenum, probably because it has more exposure to gluten. The inflammation lasts as long as gluten ingestion continues.

Clinical Manifestations

Classic manifestations of celiac disease include foul-smelling diarrhea, steatorrhea, flatulence, abdominal distention, and malnutrition.[48] Some people have no obvious GI symptoms and may instead have atypical signs and symptoms such as decreased bone density and osteoporosis, dental enamel hypoplasia, iron and folate deficiencies, peripheral neuropathy, and reproductive problems. A pruritic, vesicular skin lesion, called *dermatitis herpetiformis,* is sometimes present and occurs as a rash on the buttocks, scalp, face, elbows, and knees.[48] Celiac disease is also associated with other autoimmune diseases, particularly rheumatoid arthritis, type 1 diabetes mellitus, and thyroid disease. The link between celiac disease and reproductive problems is less clear.

Protein, fat, and carbohydrate absorption is affected. Weight loss, muscle wasting, and other signs of malnutrition may be present. Abnormal serum folate, iron, and cobalamin levels can occur. Iron-deficiency anemia is one of the most common manifestations of celiac disease. Patients may exhibit lactose intolerance and need to refrain from lactose-containing products until the disease is under control. Inadequate calcium intake and vitamin D absorption can lead to decreased bone density and osteoporosis.

Diagnostic Studies and Collaborative Care

Early diagnosis and treatment can prevent complications. Screening is recommended for close relatives of patients known to have the disease, young patients with decreased bone density, those with anemia once other causes are ruled out, and certain autoimmune diseases.

Celiac disease is confirmed by (1) histologic evidence of the disease when a biopsy is taken from the small intestine and (2) the symptoms and histologic evidence disappearing when the person eats a gluten-free diet. Diagnostic testing must be done before the person is placed on a gluten-free diet, since the diet will alter the results. Serologic testing for immunoglobulin A (IgA) antitissue transglutaminase and IgA endomysial antibody provides good sensitivity and specificity. Histologic evidence remains the gold standard for confirming the diagnosis. Biopsies show flattened mucosa and noticeable losses of villi. Genotyping involves testing for HLA-DQ2 and/or HLA-DQ8 antigens. Many people spend years seeking treatment for nonspecific complaints before celiac disease is eventually diagnosed.

Treatment with a gluten-free diet (Table 43-33) halts the process. Most patients recover completely within 3 to 6 months of treatment, but they need to maintain a gluten-free diet for the rest of their lives. If the disease is untreated, chronic inflammation and hyperplasia continue. Individuals with celiac disease have an increased risk of non-Hodgkin's lymphoma and GI cancers.

Teach the patient to avoid wheat, barley, oats, and rye products. Although pure oats do not contain gluten, oat products can become contaminated with wheat, rye, and barley during the milling process. Gluten is also found in some medications and in many food additives, preservatives, and stabilizers. A combination of corticosteroids and a gluten-free diet is used to treat individuals with refractory celiac disease who do not respond to a gluten-free diet alone.

Maintenance of a gluten-free diet is difficult, particularly when traveling or eating in restaurants.[49-51] Therefore dietary consultation is imperative. The patient needs to know where to purchase gluten-free products. Gluten-free products are sold in health food stores, in many grocery stores, and through Internet

TABLE 43-33 NUTRITIONAL THERAPY

Celiac Disease

Foods to Eat*	Foods to Avoid
• Eggs • Potatoes • Butter • Cheese, cottage cheese • Meat, fish, poultry (not marinated or breaded) • Yogurt • Fresh fruits • Tapioca • Corn tortillas • Flax, corn, and rice • Soy products • Gluten-free breads, crackers, pasta, and cereals • Unflavored milk • Peanut butter • Coffee, tea, and cocoa	• Wheat • Barley • Oats • Rye • Flour (unless it says gluten-free flour, or is made purely from a nongluten source, such as rice flour) • Baked goods, including muffins, cookies, cakes, pies • Bread, including wheat bread, white bread, "potato" bread • Pasta, pizza, bagels

*Read food labels to look for gluten stabilizers or ingredients that contain gluten.

sites. Check the Internet to get a list of grocery stores that sell gluten-free products. Patients may need referral for financial assistance, since gluten-free products are more expensive than regular foods. The Celiac Sprue Association website *(www.csaceliacs.info)* and the Celiac Disease Foundation *(www.celiac.org)* provide suggestions for maintaining a gluten-free diet and living with celiac disease.

Continually encourage and motivate patients to continue the gluten-free diet. Reinforce that nonadherence to the diet will result in chronic inflammation, which can lead to complications such as anemia and osteoporosis.

LACTASE DEFICIENCY

Lactase deficiency is a condition in which the lactase enzyme is deficient or absent. Lactase is the enzyme that breaks down lactose into two simple sugars: glucose and galactose. Primary lactase insufficiency is most commonly a result of genetic factors. Certain ethnic or racial groups, especially those with Asian or African ancestry, develop low lactase levels in childhood. Less common causes include low lactase levels resulting from premature birth and congenital lactase deficiency, a rare genetic disorder. Lactose malabsorption can also occur when conditions leading to bacterial overgrowth promote lactose fermentation in the small bowel, and when intestinal mucosal damage interferes with absorption. The latter occurs with IBD and celiac disease.

The symptoms of lactose intolerance include bloating, flatulence, cramping abdominal pain, and diarrhea. Symptoms generally occur within 30 minutes to several hours after drinking a glass of milk or ingesting a milk product. The diarrhea of lactose intolerance results from fluid secretion into the small intestine, responding to the osmotic action of undigested lactose.

Many lactose-intolerant persons are aware of their milk intolerance and avoid milk and milk products. Lactose intolerance is diagnosed with a lactose tolerance test, a lactose hydrogen breath test, or genetic testing.

Treatment consists of eliminating lactose from the diet by avoiding milk and milk products and/or replacing lactase with commercially available preparations. Milk and ice cream contain more lactose than cheese. Live culture yogurt is an alternative source of calcium, but the patient needs to be sure that milk products have not been added to the yogurt.

A lactose-free diet is given initially and may be gradually advanced to a low-lactose diet as tolerated by the patient. Teach the patient that adherence to the diet is important. Many lactose-intolerant persons may not exhibit symptoms if lactose is taken in small amounts. In some persons, lactose may be tolerated better if taken with meals. Since avoidance of milk and milk products can lead to calcium deficiency, supplements may be necessary to prevent osteoporosis. Lactase enzyme (Lactaid) is available commercially as an over-the-counter (OTC) product. It is mixed with milk and breaks down the lactose before the milk is ingested.

SHORT BOWEL SYNDROME

Short bowel syndrome (SBS) is a condition in which the small intestine does not have adequate surface area to absorb enough nutrients. Thus the person is unable to meet energy, fluid, electrolyte, and nutritional needs on a standard diet. Causes of SBS include diseases that damage the intestinal mucosa, surgical removal of too much small intestine (primarily in patients with Crohn's disease), and congenital defects. Without adequate surface area, lifetime parenteral nutrition is necessary for survival.

Resections of up to 50% of the small intestine cause little disturbance of bowel function, especially if the terminal ileum and ileocecal valve remain intact. The remaining intestine undergoes adaptive changes that are more pronounced in the ileum. The villi and crypts increase in size, and the absorptive capacity of the remaining intestine increases.

Clinical Manifestations

The predominant manifestations of SBS are diarrhea and steatorrhea (unabsorbed fat in the stool). Signs of malnutrition as well as vitamin and mineral deficiencies include weight loss, cobalamin and zinc deficiency, and hypocalcemia. The patient may develop lactase deficiency and bacterial overgrowth. Oxalate kidney stones may form because of increased colonic absorption of oxalate.

Collaborative Care

The overall goals of treatment are that the patient with SBS will have fluid and electrolyte balance, normal nutritional status, and control of diarrhea. In the period immediately following massive bowel resection, patients receive parenteral nutrition to replace fluid, electrolyte, and nutrient losses and to rest the bowel. An antisecretory agent (histamine [H_2]-blocker or proton pump inhibitor) may be given to decrease gastric acid secretion.

A diet high in carbohydrate and low in fat supplemented with soluble fiber, pectin, and the amino acid glutamine is often recommended. The patient with SBS is encouraged to eat at least six meals per day to increase the time of contact between food and the intestine. Oral intake can be supplemented with elemental nutrient formulas and tube feeding during the night. For patients with severe malabsorption, parenteral nutrition (see Chapter 40) may be used.[52] Oral supplements of calcium, zinc, and multivitamins are typically recommended.

Teduglutide (Gattex) is used in SBS in patients who need additional nutrition from parenteral nutrition. It is a subcutaneous injection given once daily that helps to improve intestinal absorption of fluids and nutrients, reducing the frequency and volume of parenteral nutrition.

Opioid antidiarrheal drugs are the most effective in decreasing intestinal motility (see Table 43-2). For patients who have limited ileal resections (less than 39 in [99 cm]), cholestyramine (Questran) reduces diarrhea resulting from unabsorbed bile acids by increasing their excretion in feces. Bile acids stimulate intestinal fluid secretion and reduce colonic fluid absorption.

Intestinal transplantation is a procedure performed at a few specialized transplant centers in the United States. Candidates for this procedure are patients with SBS, dependence on parenteral nutrition, and chronic liver disease. It is often considered a last-resort treatment option for patients with intestinal failure who develop life-threatening complications from parenteral nutrition. Transplantation may include the intestine alone, liver and intestine, or multivisceral combinations (stomach, duodenum, jejunum, ileum, colon, and pancreas).

GASTROINTESTINAL STROMAL TUMORS

Gastrointestinal stromal tumors (GISTs) are a rare form of cancer that originates in cells found in the wall of the GI tract.[53] These cells, known as interstitial cells of Cajal, help control the movement of food and liquid through the stomach and intestines. About 55% of GISTs are found in the stomach; 35% are found in the small intestine; 5% are found in the rectum; and the rest are found in the esophagus, colon, or peritoneum.[53] GISTs are most frequently diagnosed in people between the ages of 50 and 70. Most GISTs are caused by genetic mutations.

The manifestations of GISTs depend on the part of the GI tract affected. Early manifestations are often subtle, including early satiety, bloating, nausea, and vomiting. Because these manifestations are similar to those of many other GI problems, the cancer is difficult to detect early. Later manifestations may include GI bleeding and obstruction caused by growth of the tumor. Often the GIST is found during evaluation (e.g., endoscopy, x-ray) for other problems such as CRC or stomach cancer. The diagnosis of GIST is based on histologic examination of biopsied tissue. Endoscopic ultrasound can be used to determine the extent of the tumor.

Patients initially undergo surgery to remove the tumor, but the GIST has often metastasized by the time of diagnosis or commonly recurs. GISTs are unresponsive to conventional chemotherapy. However, discovery of genetic mutations led to the development of tyrosine kinase inhibitor drugs (e.g., imatinib mesylate [Gleevec]) that are highly effective against GISTs.[43] (Targeted drug therapies are discussed in Chapter 16.)

ANORECTAL PROBLEMS

HEMORRHOIDS

Hemorrhoids are dilated hemorrhoidal veins. They may be internal (occurring above the internal sphincter) or external (occurring outside the external sphincter) (Figs. 43-15 and 43-16). Symptoms include rectal bleeding, pruritus, prolapse, and pain. In affected persons, hemorrhoids appear periodically, depending on the amount of anorectal pressure.

Etiology and Pathophysiology

Hemorrhoids develop as a result of increased anal pressure and weakened connective tissue that normally supports the hemorrhoidal veins. When supporting tissues in the anal canal weaken, usually as a result of straining at defecation, venules become dilated. In addition, blood flow through the veins of the hemorrhoidal plexus is impaired. An intravascular clot in the venule results in a thrombosed external hemorrhoid.

Hemorrhoids are the most common reason for bleeding with defecation. The amount of blood lost at one time may be small, but over time it may lead to iron-deficiency anemia. Hemorrhoids may be precipitated by many factors, including pregnancy, prolonged constipation, straining in an effort to defecate, heavy lifting, prolonged standing and sitting, and portal hypertension (as found in cirrhosis).

Clinical Manifestations

The classic manifestations of hemorrhoidal disease include bleeding, anal pruritus, prolapse, and pain. The patient with internal hemorrhoids may be asymptomatic. However, when internal hemorrhoids become constricted, the patient will report pain. Internal hemorrhoids can bleed, resulting in blood on toilet paper after defecation or blood on the outside of stool. The patient may report a chronic, dull, aching discomfort, particularly when the hemorrhoids have prolapsed.

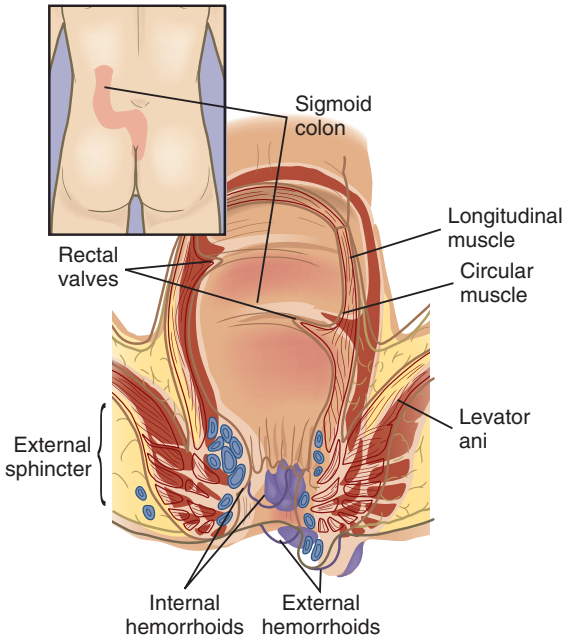


FIG. 43-15 Anatomic structures of the rectum and anus with external and internal hemorrhoids.

External hemorrhoids are reddish blue and seldom bleed. Blood clots in external hemorrhoids cause pain and inflammation, and the hemorrhoids are described as thrombosed. External hemorrhoids cause intermittent pain, pain on palpation, itching, and burning. Patients also report bleeding associated with defecation. Constipation or diarrhea can aggravate these symptoms.

Diagnostic Studies and Collaborative Care

Internal hemorrhoids are diagnosed by digital examination, anoscopy, and sigmoidoscopy. External hemorrhoids can be diagnosed by visual inspection and digital examination.

Therapy is directed toward the causes and the patient's symptoms. A high-fiber diet and increased fluid intake prevent constipation and reduce straining, which allows engorgement of the veins to subside. The resulting stool bulk may also decrease stool leakage and therefore itching. Ointments such as dibucaine; creams, suppositories, and impregnated pads that contain

FIG. 43-16 Thrombosed external hemorrhoids.

antiinflammatory agents (e.g., hydrocortisone); or astringents and anesthetics (e.g., witch hazel, benzocaine) may be used to shrink the mucous membranes and relieve discomfort. The use of topical corticosteroids such as hydrocortisone agents should be limited to 1 week or less to prevent side effects such as contact dermatitis and mucosal atrophy. Stool softeners may be ordered to keep the stools soft, and sitz baths help relieve pain.

External hemorrhoids are usually managed by conservative therapy unless they become thrombosed. For internal hemorrhoids, nonsurgical approaches (rubber band ligation, infrared coagulation, cryotherapy, laser treatment) can be used. Rubber band ligation is the most widely used technique. An anoscope is inserted so the hemorrhoid can be identified and then ligated with a rubber band. The rubber band around the hemorrhoid constricts circulation, and the tissue becomes necrotic, separates, and sloughs off. There is some local discomfort with this procedure, but no anesthetic is required. Aspirin or acetaminophen is usually given for discomfort. Infrared coagulation can be used to treat bleeding internal hemorrhoids. In this procedure, either infrared or electric current produces local inflammation. Cryotherapy involves rapid freezing of the hemorrhoid.

A *hemorrhoidectomy* is the surgical excision of hemorrhoids. Surgery is indicated when there is prolapse, excessive pain or bleeding, or large hemorrhoids. In general, hemorrhoidectomy is reserved for patients with severe symptoms related to multiple thrombosed hemorrhoids or marked protrusion. Surgical removal may be done by cautery, clamp, or excision. One surgical approach is to leave the area open so that healing takes place by secondary intention. In another approach, the hemorrhoids are removed, the tissue is sutured, and wound healing takes place by primary intention.

NURSING MANAGEMENT HEMORRHOIDS

Conservative nursing management for the patient with hemorrhoids includes teaching measures to prevent constipation, avoid prolonged standing or sitting, and properly use OTC drugs for hemorrhoidal symptoms. Teach the patient to seek medical care for severe symptoms of hemorrhoids (e.g., excessive pain and bleeding, prolapsed hemorrhoids). Sitz baths (15 to 20 minutes) two or three times each day for 7 to 10 days may help reduce discomfort and swelling associated with hemorrhoids.

Pain caused by sphincter spasm is a common problem after a hemorrhoidectomy. Be aware that although the procedure is minor, the pain is severe. Opioids are usually given initially. Postoperatively, topical nitroglycerin preparations may be used to decrease pain and subsequent opioid use.

Sitz baths are started 1 or 2 days after surgery. A warm sitz bath provides comfort and keeps the anal area clean. A sponge ring in the sitz bath helps relieve pressure on the area. Initially, the patient should not be left alone because of the possibility of weakness or fainting.

Packing may be inserted into the rectum to absorb drainage, with a T-binder used to hold the dressing in place. If packing is inserted, it usually is removed on the first or second postoperative day. Assess for rectal bleeding. The patient may be embarrassed when the dressing is changed, and privacy should be provided. The patient usually dreads the first bowel movement and often resists the urge to defecate. Pain medication may be given before the bowel movement to reduce discomfort.

A stool softener such as docusate (Colace) is usually ordered for the first few postoperative days. If the patient does not have a bowel movement within 2 or 3 days, an oil-retention enema is given. Teach the patient the importance of diet, care of the anal area, symptoms of complications (especially bleeding), and avoidance of constipation and straining. Sitz baths are recommended for 1 to 2 weeks. The health care provider may order a stool softener to be taken for a time. Hemorrhoids may recur. Occasionally, anal strictures develop and dilation is necessary. Regular checkups are important to prevent any further problems.

ANAL FISSURE

An *anal fissure* is a skin ulcer or a crack in the lining of the anal wall that is caused by trauma, local infection, or inflammation (Fig. 43-17). Fissures are considered either primary or secondary based on their etiology. *Primary fissures* usually occur as a result of local trauma, such as vaginal delivery. High pressure in the internal anal sphincter can result in ischemia, which can lead to fissuring. *Secondary fissures* are due to a variety of conditions, including IBD, prior anal surgery, and infection (syphilis; tuberculosis; gonorrhea; or infection with *Chlamydia,* herpes simplex virus, or HIV).

Anal tissue ulcerates because of ischemia caused by a combination of high resting anal sphincter tone and poor blood supply to the area. The ischemic tissue may ulcerate spontaneously or when traumatized by factors such as hard stools that would not normally cause tissue breakdown. If ischemia is not corrected, the anal fissures will not be able to heal.

The major symptoms are anal pain and bleeding. Pain is especially severe during and after defecation and has been described as "passing broken glass."[54] Bleeding is bright red and usually slight. Constipation results because of fear of pain associated with bowel movements.

Anal fissures are diagnosed through physical examination. Conservative care with fiber supplements, adequate fluid intake, sitz baths, and topical analgesics is successful in some cases, especially if the situation is acute. Topical preparations, including nitrates and calcium channel blockers, are used to decrease rectal anal pressure to allow the fissure to heal without sphincter damage. Local injections of botulinum toxin are also used to decrease rectal anal pressure, and are most effective when

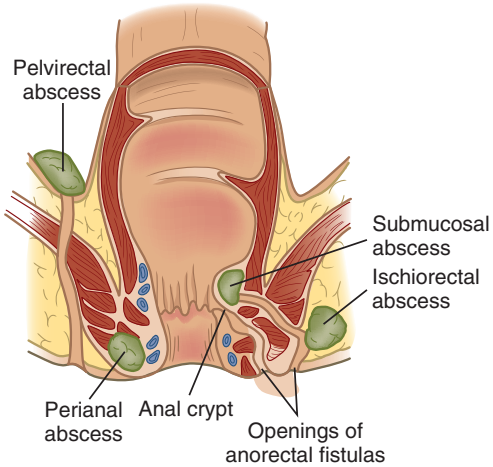

FIG. 43-17 Common sites of anorectal abscesses and fistula formation.

combined with nitrates. Pain may be decreased by softening stools with mineral oil or stool softeners. Warm sitz baths (15 to 20 minutes, three times per day) and anal anesthetic suppositories with hydrocortisone (Anusol-HC) are also ordered.

If topical medications are ineffective, a lateral internal sphincterotomy is the recommended surgical procedure, but it carries the risk of postoperative incontinence. Postoperative nursing care is the same as the care for the patient who has had a hemorrhoidectomy.

ANORECTAL ABSCESS

An *anorectal abscess* is a collection of perianal pus (see Fig. 43-17). The abscess is the result of obstruction of the anal glands, leading to infection and subsequent abscess formation. Abscess formation can occur secondary to anal fissures, trauma, or IBD. The most common causative organisms are *Escherichia coli*, staphylococci, and streptococci. Clinical manifestations include local severe pain and swelling, foul-smelling drainage, tenderness, and elevated temperature. Sepsis can occur as a complication. Anorectal abscesses are diagnosed by rectal examination.

Surgical therapy consists of drainage of abscesses. If packing is used, it should be impregnated with petroleum jelly, and the area should be allowed to heal by granulation. The packing is changed every day, and moist, hot compresses are applied to the area. Care must be taken to avoid soiling the dressing during urination or defecation. A low-fiber diet is given. The patient may leave the hospital with the wound still open. Teach the patient about wound care and the importance of sitz baths, thorough cleaning after bowel movements, and follow-up visits to a health care provider.

ANAL FISTULA

An **anal fistula** is an abnormal tunnel leading from the anus or rectum. It may extend to the outside of the skin, vagina, or buttocks and often precedes an abscess. Anal fistulas are a complication of Crohn's disease and may resolve when drug treatment (i.e., with infliximab) achieves remission of the disease. About 50% of anal fistulas are due to anorectal abscess.

Feces may enter the fistula and cause an infection. There may be persistent, blood-stained, purulent discharge or stool leakage from the fistula. The patient may need to wear a pad to avoid staining clothes.

Surgical therapy involves a fistulotomy or a fistulectomy. In a fistulotomy the fistula is opened, and healthy tissue is allowed to granulate. A fistulectomy is an excision of the entire fistulous tract. Gauze packing is inserted, and the wound is allowed to heal by granulation. Care is the same as that given after a hemorrhoidectomy. In patients with complex fistulas, fibrin glue may be injected to seal the fistula.

ANAL CANCER

Anal cancer is uncommon in the general population, but the incidence is increasing. Human papillomavirus (HPV) is associated with about 80% of the cases of anal cancer. The American Cancer Society estimates that about 7100 people are diagnosed with anal cancer each year in the United States, with more women diagnosed than men.[55] Risk factors include having many sexual partners, genital warts (which are caused by HPV), smoking, receptive anal sex, and HIV infection. The average age at diagnosis is 60. Anal cancer is more common in African Americans than in whites.

Most frequently the initial symptom is rectal bleeding. Other symptoms include rectal pain and sensation of a rectal mass. Some patients have no symptoms, which leads to delayed diagnosis and treatment.

It is especially important to screen high-risk individuals. A swab of the anal mucosa can be obtained during a digital rectal examination. Identification of cell changes (e.g., dysplasia, neoplasia) can be determined. High-resolution anoscopy allows for visualization of the mucosa and biopsy. An endo-anal *(endorectal) ultrasound* may also be done.

The use of condoms to reduce the transmission of HPV is recommended. The HPV vaccine Gardasil is used for the prevention of anal cancer and associated precancerous lesions caused by HPV types 6, 11, 16, and 18. Gardasil is also approved for the prevention of cervical, vulvar, and vaginal cancer and the associated precancerous lesions caused by HPV in women. (It is also approved for the prevention of genital warts in men and women.) Another HPV vaccine, Cervarix, may also be useful in the prevention of HPV-associated anal cancer. After vaccination with HPV vaccine, patients at risk need to continue their recommended screening program.

Treatment of anal cancer depends on the size and depth of the lesions. Topical therapy with bichloroacetic or trichloroacetic acid may be used to kill the HPV virus. Imiquimod (Aldara), an immunomodulator, is also used as a topical agent. Therapy also includes surgery, radiation, and chemotherapy. Chemotherapy may include mitomycin, cisplatin (Platinol), and 5-FU.

PILONIDAL SINUS

A *pilonidal sinus* is a small tract under the skin between the buttocks in the sacrococcygeal area. It is thought to be of congenital origin. It may have several openings and is lined with epithelium and hair, hence the name *pilonidal* ("a nest of hair"). The skin is moist, and movement of the buttocks causes the short, wiry hair to penetrate the skin. The irritated skin becomes infected and forms a pilonidal cyst or abscess. There are no symptoms unless there is an infection. If it becomes infected, the patient complains of pain and swelling at the base of the spine.

The formed abscess requires incision and drainage. The wound may be closed or left open to heal by secondary intention. The wound is packed, and sitz baths are ordered. Nursing care includes warm, moist heat applications when an abscess is present. The patient is usually more comfortable lying on the abdomen or side. Teach the patient to avoid contaminating the dressing when urinating or defecating and to avoid straining whenever possible.

CASE STUDY

Colorectal Cancer

iStockphoto/Thinkstock

Patient Profile

L.C., a 58-year-old Native American man, is from a Pueblo tribe in northern New Mexico. L.C.'s wife and family drove 50 miles to take him to the Indian Health Service hospital because of his deteriorating health (see the case study in Chapter 39).

Subjective Data

See the case study in Chapter 39 on p. 874.

Objective Data

Physical Examination

See the case study in Chapter 39 on p. 877.

Laboratory Tests

- CT scan and colonoscopy show two medium-sized tumors in the transverse colon

Collaborative Care

Surgical Procedure

- Tranverse hemicolectomy performed and lymph node biopsies taken
- Pathology results indicate that the adenocarcinoma tumor has invaded the muscle wall of colon and 2 out of 5 lymph nodes are positive for cancer

Postoperative

- Feels like his life has ended and does not want to leave hospital.
- States that there is no one to take care of him at his home and he is far away from the hospital.

Follow-Up Treatment

- Scheduled for outpatient chemotherapy

Discussion Questions

1. What are the signs and symptoms of colorectal cancer that L.C. manifested (see the case study in Chapter 39 on p. 874)?
2. What types of diagnostic information are available from a colonoscopy versus a sigmoidoscopy?
3. What stage of CRC does L.C. probably have? What treatment is recommended for this stage of CRC?
4. How could you provide emotional support to L.C. and his family?
5. What is a culturally sensitive way for you to support L.C. and his family in making decisions about his continued health care?
6. ***Priority Decision:*** Based on the assessment data, what are the priority nursing diagnoses? Are there any collaborative problems?
7. ***Priority Decision:*** What are the priority nursing interventions for L.C. at this stage of his illness?
8. ***Evidence-Based Practice:*** L.C. had not had a previous colonoscopy. He is worried that other members of his family may have colon cancer. What can you tell him about the recommendations for colorectal cancer screening?

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. The appropriate collaborative therapy for the patient with acute diarrhea caused by a viral infection is to
   a. increase fluid intake.
   b. administer an antibiotic.
   c. administer antimotility drugs.
   d. quarantine the patient to prevent spread of the virus.
2. When a 35-year-old female patient is admitted to the emergency department with acute abdominal pain, which possible diagnosis should you consider that may be the cause of her pain *(select all that apply)?*
   a. Gastroenteritis
   b. Ectopic pregnancy
   c. Gastrointestinal bleeding
   d. Irritable bowel syndrome
   e. Inflammatory bowel disease
3. Assessment findings suggestive of peritonitis include
   a. rebound abdominal pain.
   b. a soft, distended abdomen.
   c. dull, continuous abdominal pain.
   d. observing that the patient is restless.
4. In planning care for the patient with Crohn's disease, the nurse recognizes that a major difference between ulcerative colitis and Crohn's disease is that Crohn's disease
   a. frequently results in toxic megacolon.
   b. causes fewer nutritional deficiencies than ulcerative colitis.
   c. often recurs after surgery, whereas ulcerative colitis is curable with a colectomy.
   d. is manifested by rectal bleeding and anemia more frequently than is ulcerative colitis.
5. The nurse performs a detailed assessment of the abdomen of a patient with a possible bowel obstruction, knowing that manifestations of an obstruction in the large intestine are *(select all that apply)*
   a. persistent abdominal pain.
   b. marked abdominal distention.
   c. diarrhea that is loose or liquid.
   d. colicky, severe, intermittent pain.
   e. profuse vomiting that relieves abdominal pain.
6. A patient with stage I colorectal cancer is scheduled for surgery. Patient teaching for this patient would include an explanation that
   a. chemotherapy will begin after the patient recovers from the surgery.
   b. both chemotherapy and radiation can be used as palliative treatments.
   c. follow-up colonoscopies will be needed to ensure that the cancer does not recur.
   d. a wound, ostomy, and continence nurse will visit the patient to identify an abdominal site for the ostomy.
7. The nurse explains to the patient undergoing ostomy surgery that the procedure that maintains the most normal functioning of the bowel is
   a. a sigmoid colostomy.
   b. a transverse colostomy.
   c. a descending colostomy.
   d. an ascending colostomy.
8. In contrast to diverticulitis, the patient with diverticulosis
   a. has rectal bleeding.
   b. often has no symptoms.
   c. has localized cramping pain.
   d. frequently develops peritonitis.

9. A nursing intervention that is most appropriate to decrease postoperative edema and pain after an inguinal herniorrhaphy is
   a. applying a truss to the hernia site.
   b. allowing the patient to stand to void.
   c. supporting the incision during coughing.
   d. applying a scrotal support with ice bag.
10. The nurse determines that the goals of dietary teaching have been met when the patient with celiac disease selects from the menu
   a. scrambled eggs and sausage.
   b. buckwheat pancakes with syrup.
   c. oatmeal, skim milk, and orange juice.
   d. yogurt, strawberries, and rye toast with butter.
11. What should a patient be taught after a hemorrhoidectomy?
   a. Take mineral oil before bedtime.
   b. Eat a low-fiber diet to rest the colon.
   c. Administer oil-retention enema to empty the colon.
   d. Use prescribed pain medication before a bowel movement.

1. a, 2. a, b, c, d, e, 3. a, 4. c, 5. a, b, 6. c, 7. a, 8. b, 9. d, 10. a, 11. d

LEARNING OUTCOMES

1. Differentiate among the types of viral hepatitis, including etiology, pathophysiology, clinical manifestations, complications, and collaborative care.
2. Describe the nursing management of the patient with viral hepatitis.
3. Describe the pathophysiology, clinical manifestations, complications, and collaborative care of the patient with nonalcoholic fatty liver disease.
4. Explain the etiology, pathophysiology, clinical manifestations, complications, collaborative care, and nursing management of the patient with cirrhosis of the liver.
5. Describe the clinical manifestations and management of liver cancer.
6. Differentiate between acute and chronic pancreatitis related to pathophysiology, clinical manifestations, complications, collaborative care, and nursing management.
7. Explain the clinical manifestations, collaborative care, and nursing management of the patient with pancreatic cancer.
8. Describe the pathophysiology, clinical manifestations, complications, and collaborative care of gallbladder disorders.
9. Describe the nursing management of the patient undergoing surgical treatment of cholecystitis and cholelithiasis.

Nursing management of patients with liver, pancreatic, and gallbladder problems is the focus of this chapter. Viral hepatitis, cirrhosis, acute pancreatitis, cholecystitis, and cholelithiasis are described in detail.

DISORDERS OF THE LIVER

HEPATITIS

Hepatitis is a broad term that means inflammation of the liver. Hepatitis is most commonly caused by viruses but can also be caused by drugs (alcohol), chemicals (see Table 39-6), autoimmune diseases, and metabolic abnormalities.

Viral Hepatitis

The types of viral hepatitis are A, B, C, D, and E. They differ in their modes of transmission and clinical manifestations (Table 44-1). The different hepatitis viruses can be responsible for both acute and chronic liver disease.

Other less common viruses can also cause liver disease. These include cytomegalovirus (CMV), Epstein-Barr virus (EBV), herpesvirus, coxsackievirus, and rubella virus.

Hepatitis A Virus. Hepatitis A viral infection can cause a mild flu-like illness or acute hepatitis with jaundice. It can also cause acute liver failure. It does not result in a chronic (long-term) infection. In the United States the incidence of hepatitis A viral infection has declined since vaccination was recommended for at-risk persons and children (at the age of 1 year).[1]

Hepatitis A virus (HAV) is a ribonucleic acid (RNA) virus that is transmitted primarily through the fecal-oral route. It frequently occurs in small outbreaks caused by fecal contamination of food or drinking water. Poor hygiene, improper handling of food, crowded situations, and poor sanitary conditions are contributing factors. Transmission occurs between family members, institutionalized individuals, and children in day care centers. Foodborne hepatitis A outbreaks are usually due to food contaminated by an infected food handler.

The virus is present in feces during the incubation period, so it can be carried and transmitted by persons who have undetectable, subclinical infections. The greatest risk of transmission occurs before clinical symptoms are apparent. HAV is found in feces 2 or more weeks before the onset of symptoms and up to 1 week after the onset of jaundice (Fig. 44-1). It is present only briefly in blood. Anti-HAV (antibody to HAV) immunoglobulin (Ig) M appears in the serum as the stool becomes negative for the virus. Detection of hepatitis A IgM indicates acute hepatitis. Although not commonly tested clinically, hepatitis A IgG indicates past infection. IgG antibody

FIG. 44-1 Jaundiced patient.

TABLE 44-1 CHARACTERISTICS OF HEPATITIS VIRUSES

Incubation Period and Mode of Transmission	Sources of Infection	Infectivity
Hepatitis A Virus (HAV) 15-50 days (average 28) Fecal-oral (primarily fecal contamination and oral ingestion)	Crowded conditions (e.g., day care, nursing home). Poor personal hygiene. Poor sanitation. Contaminated food, milk, water, shellfish. Persons with subclinical infections, infected food handlers; sexual contact, IV drug users.	Most infectious during 2 wk before onset of symptoms. Infectious until 1-2 wk after the start of symptoms.
Hepatitis B Virus (HBV) 45-180 days (average 56-96) Percutaneous (parenteral) or permucosal exposure to blood or blood products Sexual contact Perinatal transmission	Contaminated needles, syringes, and blood products. Sexual activity with infected partners. Asymptomatic carriers. Tattoos or body piercing with contaminated needles.	Before and after symptoms appear. Infectious for 4-6 mo. Carriers continue to be infectious for life.
Hepatitis C Virus (HCV) 14-180 days (average 56) Percutaneous (parenteral) or mucosal exposure to blood or blood products High-risk sexual contact Perinatal contact	Blood and blood products. Needles and syringes. Sexual activity with infected partners.	1-2 wk before symptoms appear. Continues during clinical course. 75%-85% go on to develop chronic hepatitis C and remain infectious.
Hepatitis D Virus (HDV) 2-26 wk HBV must precede HDV Chronic carriers of HBV always at risk	Same as HBV. Can cause infection only when HBV is present. Routes of transmission same as for HBV.	Blood infectious at all stages of HDV infection.
Hepatitis E Virus (HEV) 15-64 days (average 26-42 days) Fecal-oral route Outbreaks associated with contaminated water supply in developing countries	Contaminated water, poor sanitation. Found in Asia, Africa, and Mexico. Not common in United States.	Not known. May be similar to HAV.

provides lifelong immunity (Fig. 44-2). Hepatitis A vaccination and thorough hand washing are the best measures to prevent outbreaks.

Hepatitis B Virus. Hepatitis B virus (HBV) can cause either acute or chronic disease. Transmission occurs when the virus (from infected blood or body fluids) enters the body of an uninfected person who has not received the HBV vaccine. Since the 1990s, the incidence of HBV infection has decreased because of the widespread use of the HBV vaccine.[1]

About 12 million Americans have been infected with HBV. In the majority of adults with acute hepatitis B, the infection completely resolves. Of the more than 1 million Americans who develop chronic infections, liver impairment may range from a normal liver to severe liver disease. Approximately 15% to 25% of chronically infected persons die from chronic liver disease.

HBV is a deoxyribonucleic acid (DNA) virus. It can be transmitted perinatally by mothers infected with HBV; percutaneously (e.g., IV drug use, accidental needle-stick punctures); or by mucosal exposure to infectious blood, blood products, or other body fluids (e.g., semen, vaginal secretions, saliva). In people with HBV, hepatitis B surface antigen (HBsAg) has been detected in almost every body fluid. Infected semen and saliva contain much lower concentrations of HBV than blood, but the virus can be transmitted via these secretions. If gastrointestinal (GI) bleeding occurs, feces can be contaminated with the virus from the blood. There is no evidence that urine, feces (without GI bleeding), breast milk, tears, and sweat are infective. Organ and tissue transplantation is another potential source of infection. In some patients with acute hepatitis B, there is no readily identifiable risk factor.[1]

Sexual transmission is a common mode of HBV transmission. Men who have sex with men (especially those practicing unprotected anal intercourse) are at risk for HBV infection. Although the risk of transmission is much lower, kissing and sharing food items may spread the virus via saliva. Other at-risk individuals include those who live with chronically infected persons, hemodialysis patients, and health care and public safety workers. HBV can live on a dry surface for at least 7 days; it is much more infectious than human immunodeficiency virus (HIV).

HBV is a complex structure with three distinct antigens: the surface antigen (HBsAg), the core antigen (HBcAg), and the e antigen (HBeAg). HBsAg in the serum for 6 months or longer after infection indicates chronic HBV infection. Each antigen has a corresponding antibody that may develop in response to HBV infection. The presence of hepatitis B surface antibody (anti-HBs) in the blood indicates immunity from the HBV vaccine or from past HBV infection (Fig. 44-3).

Hepatitis C Virus. Infection with the hepatitis C virus (HCV) can result in both acute and chronic illness. Acute hepatitis C, which is usually asymptomatic, can be difficult to detect unless diagnosed with laboratory testing. The most common causes of acute hepatitis C are injection drug use and outbreaks among HIV-positive men who have sex with men.

The majority of patients who acquire hepatitis C usually develop chronic infection.[2] Most are unaware of their infection. Chronic HCV results in a potentially progressive liver disease, with 20% to 30% of these patients developing cirrhosis. Hepa-

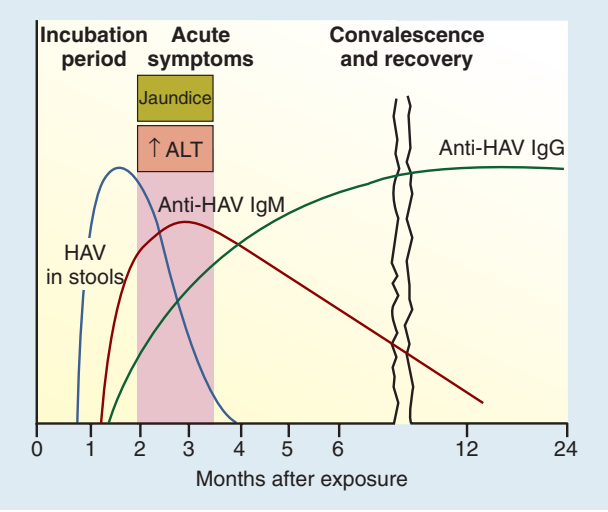

FIG. 44-2 Course of infection with hepatitis A virus *(HAV). ALT,* Alanine aminotransferase.

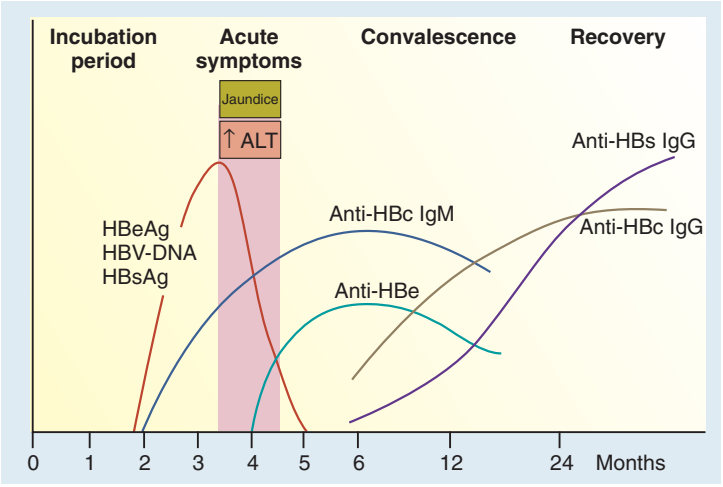

FIG. 44-3 Course of infection with hepatitis B virus *(HBV). ALT,* Alanine aminotransferase; *anti-HBc,* antibody to hepatitis B core antigen; *anti-HBe,* antibody to HBeAg; *anti-HBs,* antibody to HBsAg; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen.

titis C is the most common cause of chronic liver disease and the most common indication for liver transplantation in the United States.[3]

HCV is an RNA virus that is primarily transmitted percutaneously. The most common mode of HCV transmission is the sharing of contaminated needles and equipment among IV drug users.

The proportion of cases attributed to high-risk sexual behavior (e.g., unprotected sex, multiple partners) has increased in recent years. In the United States, 10% of all cases of HCV infection are due to occupational exposure, hemodialysis, and perinatal transmission.[2] Some patients with HCV cannot identify a source. The risk of perinatal HCV transmission is higher in women who are co-infected with both HIV and HCV.

Patients given blood or blood products before 1992 (when blood product testing for HCV began) may be at risk for chronic HCV infection and should be tested. Because of the 15- to 20-year delay between infection and the clinical appearance of liver damage, long-term effects of HCV infection pose important future health care challenges. Chronic HBV and HCV account for 80% of the cases of hepatocellular cancer.

Persons at risk for HCV infection are also at risk for HBV and HIV infections. About 30% to 40% of HIV-infected patients also have HCV. This high rate of co-infection is primarily related to IV drug use. Co-infection with HIV and HCV places the patient at greater risk for progression to cirrhosis.

Hepatitis D Virus. Hepatitis D virus (HDV), also called *delta virus,* is a defective single-stranded RNA virus that cannot survive on its own. It requires hepatitis B to replicate. It can be acquired at the same time as HBV, or a person with HBV can be infected with HDV at a later time. HDV is transmitted percutaneously, similar to HBV. It can cause a spectrum of illness ranging from an asymptomatic chronic carrier state to acute liver failure. There is no vaccine for HDV. However, vaccination against HBV reduces the risk of HDV co-infection.

Hepatitis E Virus. Hepatitis E virus (HEV) is an RNA virus transmitted by the fecal-oral route. The usual mode of transmission is drinking contaminated water. Hepatitis E infection occurs primarily in developing countries, with epidemics reported in India, Asia, Mexico, and Africa. Only a few cases of HEV have been reported in the United States, primarily in persons who recently traveled to an HEV-endemic area.

Pathophysiology

Liver. During an acute viral hepatitis infection, liver damage is mediated by cytotoxic cytokines and natural killer cells that cause lysis of infected hepatocytes. Inflammation can interrupt bile flow (cholestasis). After resolution of an acute infection, liver cells can regenerate and, if no complications occur, resume their normal appearance and function.

A chronic viral hepatitis infection causes chronic inflammation and can cause fibrosis that (over decades) can progress to cirrhosis. (Cirrhosis is discussed later in this chapter.)

Systemic Effects. The antigen-antibody complexes between the virus and its corresponding antibody may form circulating immune complexes in the early phases of hepatitis. The circulating immune complexes activate the complement system (see Chapter 12). The clinical manifestations of this activation are rash, angioedema, arthritis, fever, and malaise. *Cryoglobulinemia* (abnormal proteins found in the blood), glomerulonephritis, and vasculitis have also been found secondary to immune complex activation.

TABLE 44-2 MANIFESTATIONS OF HEPATITIS

Acute Hepatitis	Chronic Hepatitis
• Anorexia • Nausea, vomiting • Right upper quadrant discomfort • Constipation or diarrhea • Decreased sense of taste and smell • Malaise • Headache • Fever • Arthralgias • Urticaria • Hepatomegaly • Splenomegaly • Weight loss • Jaundice • Pruritus • Dark urine • Bilirubinuria • Light stools • Fatigue • Continued hepatomegaly with tenderness • Weight loss	• Malaise • Easy fatigability • Hepatomegaly • Myalgias and/or arthralgias • Elevated liver enzymes (aspartate aminotransferase [AST] and alanine aminotransferase [ALT])

Clinical Manifestations

The clinical manifestations of viral hepatitis can be classified into acute and chronic phases (Table 44-2). A large number of patients with acute hepatitis have no symptoms. As a result, infection during the acute phase may not be detected in all patients. However, others may have intermittent or ongoing malaise, fatigue, myalgias, arthralgias, and hepatomegaly.

The acute phase usually lasts from 1 to 4 months. During the incubation period, symptoms may include malaise, anorexia and weight loss, fatigue, nausea, occasional vomiting, and abdominal (right upper quadrant) discomfort. The patient may find food repugnant, and smokers may have distaste for cigarettes. There is also a decreased sense of smell. Other symptoms may include headache, low-grade fever, arthralgias, and skin rashes. Physical examination may reveal hepatomegaly, lymphadenopathy, and sometimes splenomegaly. The acute phase is the period of maximal infectivity.

The acute phase may be *icteric* (jaundice) or anicteric. (Types of jaundice are presented in Table 44-3.) **Jaundice,** a yellowish discoloration of body tissues, results from an alteration in normal bilirubin metabolism or flow of bile into the hepatic or biliary duct systems. (Normal bilirubin metabolism is presented in Fig. 39-4.) The urine may darken because of excess bilirubin being excreted by the kidneys. If conjugated bilirubin cannot flow out of the liver because of obstruction or inflammation of the bile ducts, the stools will be light or clay colored. *Pruritus* (intense chronic itching) sometimes accompanies jaundice. The pruritus occurs as a result of the accumulation of bile salts beneath the skin.

The convalescent phase following the acute phase begins as jaundice fades and lasts for weeks to months, with an average of 2 to 4 months. During this period, the patient's major complaint is malaise and easy fatigability. Hepatomegaly remains for several weeks, but splenomegaly subsides during this period.

Prior infection with HAV or HBV can provide immunity to that virus *(homologous immunity).* However, the patient can still

TABLE 44-3 CLASSIFICATION OF JAUNDICE

	Hemolytic Jaundice	Hepatocellular Jaundice	Obstructive Jaundice
Causes	• Blood transfusion reactions, sickle cell crisis, hemolytic anemia.	• Hepatitis, cirrhosis, hepatocellular carcinoma.	• Hepatitis, cirrhosis, hepatocellular carcinoma. Common bile duct obstruction from stone(s), biliary strictures, sclerosing cholangitis, and pancreatic cancer.
Description	• Caused by increased breakdown of RBCs, which produces an increased amount of unconjugated bilirubin in blood. • Liver is unable to handle increased load.	• Results from liver's altered ability to take up bilirubin from the blood or to conjugate or excrete it. • In hepatocellular disease, damaged hepatocytes leak bilirubin.	• Results from decreased or obstructed flow of bile through liver or biliary duct system. • Obstruction may occur in intrahepatic or extrahepatic bile ducts. Intrahepatic obstructions are due to swelling or fibrosis of the liver's canaliculi and bile ducts.
Diagnostic Findings			
Serum Bilirubin			
Unconjugated (indirect)	↑	↑	Somewhat ↑
Conjugated (direct)	Normal	↑ or ↓ (severe disease)	Moderately ↑
Urine Bilirubin	Negative	↑	↑
Urobilinogen			
Stool	↑	Normal, ↓	↓
Urine	↑	Normal, ↑	↓

be infected with another type of viral hepatitis. An individual with hepatitis C can be reinfected with another strain of HCV.

Complications

Most patients with acute viral hepatitis recover completely. The overall mortality rate for acute hepatitis is less than 1%. The mortality rate is higher in older adults and those with underlying debilitating illnesses (including chronic liver disease). Complications that can occur include acute liver failure, chronic hepatitis, cirrhosis of the liver, and hepatocellular carcinoma.

Almost all cases of acute hepatitis A resolve, although a small number may have a viral relapse in the first 2 to 3 months after the infection. The disappearance of jaundice does not mean the patient has totally recovered. Some HBV infections and the majority of HCV infections result in chronic (lifelong) viral infection.

Chronic HBV is more likely to develop in infants born to infected mothers and in those who acquire the infection before age 5 than in those who acquire the virus after age 5.[1] Alterations in the patient's cellular immune response may be important in the development of the chronic HBsAg carrier state and the progression of acute HBV to chronic HBV. These immune system alterations may explain why the patient with chronic kidney disease who is undergoing dialysis when hepatitis B is acquired is more at risk for developing chronic infection.[4] Persons with chronic kidney disease have a depressed cellular immune response.

HCV infection is more likely than HBV to become chronic.[5] As previously mentioned, many patients with chronic HCV infection develop chronic liver disease, cirrhosis, and hepatocellular cancer.[6] Risk factors for progression to cirrhosis include male gender, alcohol consumption, and excess iron deposition in the liver. Elevated cholesterol or triglycerides, obesity, and diabetes mellitus are also risk factors for the progression of HCV to cirrhosis.

Diagnostic Studies

The only definitive way to distinguish among the various forms of viral hepatitis is by testing the patient's blood for the specific antigen or antibody. In some types of viral hepatitis, the blood can be tested for the viral level (also known as the *viral load*). Tests for the different types of viral hepatitis are presented in Table 44-4. In viral hepatitis, many of the liver function tests show significant abnormalities. The common abnormalities are shown in Table 44-5.

Several tests are available to determine the presence of HCV. Initial testing for HCV infection includes HCV antibody testing. If the antibody test is positive, HCV RNA testing should be obtained to assess for chronic infection; a positive result confirms chronic infection. A small number of patients may have a false-positive HCV antibody test with a negative HCV RNA test. If recent HCV infection is suspected, HCV RNA testing is usually obtained because it may take several weeks or longer for HCV antibodies to develop. This testing may also be helpful in the immunocompromised patient (e.g., patient with HIV). Because of altered or delayed antibody response to HCV, these patients may not have detectable antibody levels even though they are infected with HCV.

Viral genotype testing is done in patients undergoing drug therapy for HBV or HCV infection. HBV has at least eight different genotypes (A to H). In some centers, HBV genotyping is performed before starting treatment. HBV genotype may be useful in predicting disease and treatment outcomes.[6]

HCV has six genotypes and more than 50 subtypes. In the United States, 75% of HCV infections are caused by HCV genotype 1. Genotype is one of the strongest predictors of response to drug therapy.[7] For patients who test positive for HCV, genotyping is obtained before drug therapy is started.

Physical assessment may reveal hepatic tenderness, hepatomegaly, and splenomegaly. The liver is palpable. A liver biopsy is not indicated in acute hepatitis unless the diagnosis is in doubt. In chronic hepatitis a liver biopsy may be done. Biopsy of liver tissue allows for histologic examination of liver cells and characterization of the degree of inflammation, fibrosis, or cirrhosis that may be present. A patient who has a bleeding disorder may not be an appropriate candidate for biopsy because of the risk of bleeding. In these patients a transjugular biopsy may be an option.

TABLE 44-4 TESTS FOR VIRAL HEPATITIS

Virus	Tests	Significance
A	Anti-HAV immunoglobulin M (IgM)	Acute infection.
	Anti-HAV immunoglobulin G (IgG)	Previous infection or immunization. Not routinely done in clinical practice.
B	HBsAg (hepatitis B surface antigen)	Marker of infectivity. Present in acute or chronic infection. Positive in chronic carriers.
	Anti-HBs (hepatitis B surface antibody)	Indicates previous infection with HBV or immunization.
	HBeAg (hepatitis B e antigen)	Indicates high infectivity. Used to determine the clinical management of patients with chronic hepatitis B.
	Anti-HBe (hepatitis B e antibody)	Indicates previous infection. In chronic hepatitis B, indicates a low viral load and low degree of infectivity.
	Anti-HBc (antibody to hepatitis B core antigen) IgM	Indicates acute infection. Does not appear after vaccination.
	Anti-HBc IgG	Indicates previous infection or ongoing infection with hepatitis B. Does not appear after vaccination.
	HBV DNA quantitation	Indicates active ongoing viral replication. Best indicator of viral replication and effectiveness of therapy in patient with chronic hepatitis B.
	HBV genotyping	Indicates the genotype of HBV.
C	Anti-HCV (antibody to HCV)	Marker for acute or chronic infection with HCV.
	HCV RNA quantitation	Indicates active ongoing viral replication.
	HCV genotyping	Indicates the genotype of HCV.
D	Anti-HDV	Present in past or current infection with HDV.
	HDV Ag (hepatitis D antigen)	Present within a few days after infection.
E*	Anti-HEV IgM and IgG	Present 1 wk–2 mo after illness onset.
	HEV RNA quantitation	Indicates active ongoing viral replication.

*Currently, no serologic tests to diagnose HEV infection are commercially available in the United States. However, diagnostic tests are available in research laboratories to detect IgM and IgG anti-HEV and HEV RNA levels.
A, Hepatitis A virus (HAV); *B,* hepatitis B virus (HBV); *C,* hepatitis C virus (HCV); *D,* hepatitis D virus (HDV); *E,* hepatitis E virus (HEV).

TABLE 44-5 DIAGNOSTIC FINDINGS IN ACUTE HEPATITIS

Test	Abnormal Finding	Etiology
Transaminases (aminotransferases)		
• Aspartate aminotransferase (AST)	Increased in acute phase Decreases as jaundice disappears	Liver cell injury
• Alanine aminotransferase (ALT)	Increased in acute phase Decreases as jaundice disappears	Liver cell injury
γ-Glutamyl transpeptidase (GGT)	Increased	Liver cell injury
Alkaline phosphatase	Moderately increased	Impaired excretory function of the liver
Serum proteins		
• γ-Globulin	Normal or increased	Impaired clearance from liver
• Albumin	Normal or decreased	Liver cell damage
Serum bilirubin (total)	Increased to about 8-15 mg/dL (137-257 µmol/L)	Liver cell damage
Urinary bilirubin	Increased	Conjugated hyperbilirubinemia
Urinary urobilinogen	Increased 2-5 days before jaundice	Diminished reabsorption of urobilinogen
Prothrombin time	Prolonged	Decreased prothrombin production by liver

Techniques for noninvasive assessment of liver fibrosis may eventually replace the need for liver biopsy. Options include the FibroScan, which uses an ultrasound transducer to determine liver fibrosis. FibroSure (FibroTest) is a biomarker that uses the results of serum tests (e.g., liver enzyme levels) to assess the degree of hepatic fibrosis.[8]

Collaborative Care

There is no specific treatment or therapy for acute viral hepatitis. Most patients can be managed at home. Emphasis is on measures to rest the body and assist the liver in regenerating (Table 44-6). Adequate nutrition and rest seem to be most beneficial for healing and liver cell regeneration. Rest reduces the metabolic demands on the liver and promotes cell regeneration. The degree of rest ordered depends on the severity of symptoms, but usually alternating periods of activity and rest are adequate. Counseling should include the importance of avoiding alcohol and notification of possible contacts for testing and prophylaxis, if indicated.

Drug Therapy. There are no drug therapies for the treatment of acute hepatitis A infection. Treatment of acute hepatitis B is indicated only in patients with severe hepatitis and liver failure. In persons with acute hepatitis C, treatment with pegylated interferon within the first 12 to 24 weeks of infection decreases the development of chronic hepatitis C.[2] Supportive drug therapy may include antiemetics for nausea, such as prochlorperazine (Compazine), promethazine (Phenergan), or ondansetron (Zofran).

Chronic Hepatitis B. Drug therapy for chronic HBV is focused on decreasing the viral load and liver enzymes and slowing the rate of disease progression. Long-term goals are prevention of cirrhosis, liver failure, and hepatocellular cancer.

TABLE 44-6 COLLABORATIVE CARE

Viral Hepatitis

Diagnostic

- History and physical examination
- Liver function studies
- Alanine aminotransferase (ALT)
- Aspartate aminotransferase (AST)
- Serum bilirubin
- Prothrombin time (PT) and INR
- Alkaline phosphatase
- γ-Glutamyl transpeptidase
- Hepatitis testing:
  - *Hepatitis A:* Anti-HAV IgM
  - *Hepatitis B:* HBsAg, anti-HBs, HBeAg, anti-HBe, anti-HBc IgM and IgG, HBV DNA quantitation, HBV genotyping
  - *Hepatitis C:* Anti-HCV, HCV RNA quantitation, HCV genotyping
  - *Hepatitis D:* Anti-HDV, HDV Ag
- FibroScan
- FibroSure (FibroTest)

Collaborative Therapy

Acute and Chronic

- Well-balanced diet
- Vitamin supplements
- Rest (degree of strictness varies)
- Avoidance of alcohol intake and drugs detoxified by the liver

Chronic HBV

- Standard interferon (Intron A)
- Pegylated interferon (PegIntron, Pegasys)
- Nucleoside and nucleotide analogs
  - lamivudine (Epivir)
  - adefovir (Hepsera)
  - entecavir (Baraclude)
  - telbivudine (Tyzeka)
  - tenofovir (Viread)

Chronic HCV

- Pegylated interferon
- ribavirin (Rebetol, Copegus)
- Protease inhibitors
  - telaprevir (Incivek)
  - boceprevir (Victrelis)

HAV, hepatitis A virus; *HB,* hepatitis B; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HDV Ag,* hepatitis D antigen; *HDV,* hepatitis D virus; *INR,* international normalized ratio.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Milk Thistle (Silymarin)

Scientific Evidence

- Previous studies suggested that milk thistle may benefit the liver by protecting and promoting the growth of liver cells and inhibiting inflammation. These studies were small and not well designed.
- Two rigorously designed studies found no real benefit from using milk thistle:
  - Silymarin was no better than placebo for chronic hepatitis C in people who had not responded to standard antiviral treatment.*
  - Hepatitis C patients who used silymarin had fewer and milder symptoms of liver disease and somewhat better quality of life but no change in virus activity or liver inflammation.†

Nursing Implications

- Appears to be well tolerated in recommended doses for up to 6 yr.
- May lower blood glucose.
- May interfere with the liver's cytochrome P450 enzyme system.

*Fried MW, Navarro VJ, Afdhal N, et al: Effect of silymarin (milk thistle) on liver disease in patients with chronic hepatitis C who failed interferon therapy: a randomized, placebo-controlled trial, *JAMA* 308(3):274, 2012.
†Seeff LB, Curto TM, Szabo G, et al: Herbal product use by persons enrolled in the hepatitis C Antiviral Long-Term Treatment Against Cirrhosis (HALT-C) Trial, *Hepatology* 47(2):605, 2008.

Current drug therapies for chronic HBV do not eradicate the virus, but work well to suppress viral replication and prevent complications of hepatitis B.[9] First-line therapies include pegylated interferon and nucleoside and nucleotide analogs (see Table 44-6).

Interferon. Interferon has multiple effects on the viral replication cycle. After binding to receptors on host cell membranes, the drug blocks viral entry into cells, synthesis of viral proteins, and viral assembly and release (see Fig. 14-4). There are two forms of interferon: standard (Intron A) and pegylated. Standard (conventional) interferon has a short half-life, necessitating frequent subcutaneous administrations (three times per week). In contrast, the long-acting preparations (pegylated interferons) are administered subcutaneously less frequently (just once per week), making them more convenient. In addition, with the long-acting preparations, blood levels remain high between doses, and therefore clinical responses are better.

The long-acting preparations are made by conjugating a standard interferon with polyethylene glycol (PEG), in a process known as *pegylation.* Therapeutic effects of the pegylated products (Pegasys and PegIntron) are due solely to its interferon component. The PEG component serves only to delay elimination of the drug. Because of their convenience and superior efficacy, these products are preferred to standard interferon and are used in both hepatitis B and hepatitis C treatment.

In patients with HBV receiving interferon, one third will have a significant reduction of serum HBV DNA levels, normalization of alanine aminotransferase (ALT) levels, and loss of HBeAg. The response to treatment may vary based on viral genotype. Interferon treatment is associated with a number of side effects (see eTable 44-1 on the website for this chapter). These side effects are dose related and tend to decrease in severity with continued treatment. Patients receiving interferon should have blood counts and liver function tests performed every 4 to 6 weeks.

Nucleoside and Nucleotide Analogs. HBV reproduces by making copies of its viral DNA nucleosides and nucleotides. The nucleoside and nucleotide analog drugs fool the virus into thinking they are normal building blocks for DNA. Thus the virus is unable to reproduce.

Nucleoside and nucleotide analogs do not prevent all viral reproduction, but they can substantially lower the amount of virus in the body. These medications include lamivudine (Epivir), adefovir (Hepsera), entecavir (Baraclude), telbivudine (Tyzeka), and tenofovir (Viread). These oral medications are used in the treatment of chronic HBV when there is evidence of active viral replication.

Nucleoside and nucleotide analogs have beneficial effects in terms of reducing viral load, decreasing liver damage, and decreasing liver enzymes. Most patients with HBV require long-term treatment with these medications.[10] When these drugs are stopped, the majority of patients (except those who have seroconverted) have HBV DNA and liver enzyme levels that return to pretreatment levels.

Severe exacerbations of hepatitis B have developed after discontinuation of treatment. If these drugs are discontinued, monitor liver function closely for several months.

Chronic Hepatitis C. Drug therapy is directed at eradicating the virus and preventing HCV-related complications.[11] Treatment for HCV includes pegylated interferon given with ribavirin (Rebetol, Copegus). Patients who have HCV genotype 1 also receive either telaprevir (Incivek) or boceprevir (Victrelis), which are HCV protease inhibitors.[11] Protease is an enzyme that is essential in viral replication.

Treatment of chronic hepatitis C is individualized and based on the genotype, the severity of liver disease, potential side effects, presence of co-morbid conditions, patient's readiness for treatment, and presence of other health problems (e.g., HIV). Pegylated interferon is injected once a week, and ribavirin is taken orally twice daily. Both boceprevir and telaprevir are taken orally every 8 hours. Ribavirin, given in combination with pegylated interferon, has a synergistic effect and reduces the rate of relapse following hepatitis C treatment. Ribavirin has a number of side effects (see eTable 44-1 on the website for this chapter).

DRUG ALERT: Ribavirin (Rebetol, Copegus)

- During treatment, pregnancy must be avoided both by women taking the drug and by women whose male partners are taking the drug.

Many patients with HIV also have HCV. Patients who have stable HIV and relatively intact immune systems ($CD4^+$ counts greater than 200/μL) are treated for HCV with the goal of eradicating HCV and reducing the risk of progression to cirrhosis. HCV treatment may reduce $CD4^+$ counts, and increase the patient's risk for anemia and leukopenia.

Patients who have advanced fibrosis or cirrhosis can be treated with drug therapy as long as liver decompensation (e.g., ascites, esophageal hemorrhage, jaundice, wasting, encephalopathy) is not present.

Depression or mood changes are common in patients receiving treatment for HCV. Patients need to be screened for depression and other mood disorders before starting interferon-based treatment and monitored frequently while on therapy.[12]

Nutritional Therapy. No special diet is required in the treatment of viral hepatitis. Emphasis is placed on a well-balanced diet that the patient can tolerate. During acute viral hepatitis, adequate calories are important because the patient usually loses weight. If fat content is poorly tolerated because of decreased bile production, it should be reduced. Vitamin supplements, particularly B-complex vitamins and vitamin K, are frequently used. If anorexia, nausea, and vomiting are severe, IV solutions of glucose or supplemental enteral nutrition therapy may be used. Fluid and electrolyte balance must be maintained.

NURSING MANAGEMENT VIRAL HEPATITIS

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a person with hepatitis are presented in Table 44-7.

TABLE 44-7 NURSING ASSESSMENT

Hepatitis*

Subjective Data

Important Health Information

Past health history: Hemophilia; exposure to infected persons; ingestion of contaminated food or water; exposure to benzene, carbon tetrachloride, or other hepatotoxic agents; crowded, unsanitary living conditions; exposure to contaminated needles; recent travel; organ transplant recipient; exposure to new drug regimens, hemodialysis, transfusion of blood or blood products before 1992; HIV status (if known)

Medications: Use and misuse of acetaminophen, new prescription, over-the-counter, or herbal medications or supplements

Functional Health Patterns

Health perception–health management: IV drug and alcohol abuse; malaise, distaste for cigarettes (in smokers), high-risk sexual behaviors

Nutritional-metabolic: Weight loss, anorexia, nausea, vomiting; feeling of fullness in right upper quadrant

Elimination: Dark urine; light-colored stools, constipation or diarrhea; skin rashes, hives

Activity-exercise: Fatigue, arthralgias, myalgias

Cognitive-perceptual: Right upper quadrant pain and liver tenderness, headache; pruritus

Role-relationship: Exposure as health care worker, long-term care institution resident, incarceration, homeless

Objective Data

General

Low-grade fever, lethargy, lymphadenopathy

Integumentary

Rash or other skin changes, jaundice, icteric sclera, injection sites

Gastrointestinal

Hepatomegaly, splenomegaly

Possible Diagnostic Findings

Elevated liver enzyme levels; ↑ serum total bilirubin, hypoalbuminemia, anemia, bilirubin in urine and increased urobilinogen, prolonged prothrombin time, positive tests for hepatitis, including anti-HAV IgM, HBsAg, anti-HBs, HBeAg, anti-HBe, anti-HBc IgM and IgG, HBV DNA quantitation, anti-HCV, HCV RNA quantitation, anti-HDV; HDV Ag; abnormal liver scan; abnormal results on liver biopsy

*Hepatitis includes both viral and nonviral causes.
HAV, Hepatitis A virus; *HBcAg,* hepatitis B core antigen; *HBeAg,* hepatitis B e antigen; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus; *HDV Ag,* hepatitis D antigen; *HDV,* hepatitis D virus.

NURSING DIAGNOSES

Nursing diagnoses for the patient with viral hepatitis may include, but are not limited to, the following:

- Imbalanced nutrition: less than body requirements *related to* anorexia and nausea
- Activity intolerance *related to* fatigue and weakness
- Risk for impaired liver function *related to* viral infection

Additional information is presented on nursing diagnoses for the patient with viral hepatitis in eNursing Care Plan 44-1 (on the website for this chapter).

PLANNING

The overall goals are that the patient with viral hepatitis will (1) have relief of discomfort, (2) be able to resume normal activities, and (3) return to normal liver function without complications.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Viral hepatitis is a public health problem. Your role is important in the prevention and control of this disease. It is helpful to understand the epidemiology of the different types of viral hepatitis before considering appropriate control measures. Preventive and control measures for hepatitis A, B, and C are summarized in Table 44-8.

TABLE 44-8 PREVENTIVE MEASURES FOR VIRAL HEPATITIS*

Hepatitis A	Hepatitis B and C
General Measures • Hand washing • Proper personal hygiene • Environmental sanitation • Control and screening (signs, symptoms) of food handlers • Serologic screening for those carrying virus • Active immunization: HAV vaccine	**Percutaneous Transmission** Screening of donated blood • *HBV:* HBsAg • *HCV:* Anti-HCV Use of disposable needles and syringes
Use of Immune Globulin • Early administration (1-2 wk after exposure) to those exposed • Prophylaxis for travelers to areas where hepatitis A is common if not vaccinated with HAV vaccine	**Sexual Transmission** • Acute exposure: HBIG administration to sexual partner of HBsAg-positive person • HBV vaccine series administered to uninfected sexual partners • Condoms used for sexual intercourse
Special Considerations for Health Care Personnel • Wash hands after contact with a patient or removal of gloves • Use infection control precautions†	**General Measures** • Hand washing • Avoid sharing toothbrushes and razors • HBIG administration for one-time exposure (needle stick, contact of mucous membranes with infectious material) • Active immunization: HBV vaccine
	Special Considerations for Health Care Personnel • Use infection control precautions† • Reduce contact with blood or blood-containing secretions • Handle the blood of patients as potentially infective • Dispose of needles properly • Use needleless IV access devices when available

*A suggested guideline for general practice to prevent you from contracting viral hepatitis from diagnosed and undiagnosed patients and carriers is for you to wear disposable gloves, goggles, and gowns (sometimes) when fecal or blood contamination is likely in handling (1) soiled bedpans, urinals, and catheters; and (2) when the patient's bed linens are soiled by body excreta or secretions.
†See eTable 15-1 available on the website.
HAV, Hepatitis A virus; *HBIG,* hepatitis B immune globulin; *HBsAg,* hepatitis B surface antigen; *HBV,* hepatitis B virus; *HCV,* hepatitis C virus.

Hepatitis A. Outbreaks of viral hepatitis are usually due to HAV. Preventive measures include personal and environmental hygiene and health education to promote good sanitation. Hand washing is probably the most important precaution. Teach about careful hand washing after bowel movements and before eating.

Vaccination is the best protection against HAV. All children at 1 year of age should receive the vaccine. Adults at risk should also receive the vaccine. These include people who travel to areas with increased rates of hepatitis A, men who have sex with men, injecting and noninjecting drug users, persons with clotting factor disorders (e.g., hemophilia), and persons with chronic liver disease.[1]

There are currently several forms of the HAV vaccine, including Havrix, Vaqta, and Avaxim. HAV vaccine is inactivated HAV. Primary immunization consists of a single dose administered intramuscularly (IM) in the deltoid muscle. A booster is recommended 6 to 12 months after the primary dose to ensure adequate antibody titers and long-term protection. The primary immunization provides immunity within 30 days after a single dose in more than 95% of those vaccinated.

Twinrix, a combined HAV and HBV vaccine, is available for people over 18 years of age. Immunization consists of three doses, given on a 0-, 1-, and 6-month schedule, the same schedule as that used for the single HBV vaccine. Twinrix may be given to high-risk individuals, including patients with chronic liver disease, users of illicit IV drugs, patients on hemodialysis, men who have sex with men, and people with clotting factor disorders who receive therapeutic blood products. The side effects of the vaccine are mild and usually limited to soreness and redness at the injection site.

Isolation is not required for HAV infection. For a patient with HAV infection, use infection control precautions (see eTable 15-1 available on the website for that chapter). A private room is indicated if the patient is incontinent of stool or has poor personal hygiene.

Both hepatitis A vaccine and immune globulin (IG) are used for prevention of HAV infection after exposure to an infected person *(postexposure prophylaxis).* The vaccine is used for preexposure prophylaxis, and IG can be used either before or after exposure. IG provides temporary (1 to 2 months) passive immunity and is effective for preventing hepatitis A if given within 2 weeks after exposure. IG is recommended for persons who do not have anti-HAV antibodies and are exposed as a result of close (household, day care center) contact with persons who have HAV or foodborne exposure. Because patients with HAV are most infectious just before the onset of symptoms (the preicteric phase), those exposed through household contact or foodborne outbreaks should receive IG. Although IG may not prevent infection in all persons, it may modify the illness to a subclinical infection. When hepatitis A occurs in a food handler, IG should be administered to all other food handlers at the establishment. Patrons may also need to be given IG.

Persons who have received a dose of HAV vaccine more than 1 month previously or who have a history of laboratory-confirmed HAV infection do not require IG.

Hepatitis B. The best way to reduce HBV infection is to identify those at risk, screen them for HBV, and vaccinate those who are not infected. Teach individuals at high risk of contracting HBV to reduce risks. Good hygienic practices, including hand washing and using gloves when expecting contact with blood, are important. Patients should not share razors, toothbrushes, and other personal items. Teach patients to use a condom for sexual intercourse, and the partner should be vaccinated.

The HBV vaccine is the best means of prevention. The HBV vaccines (Recombivax HB, Engerix-B) contain HBsAg, which promotes the synthesis of specific antibodies directed against HBV. The vaccine is given in a series of three IM injections in the deltoid muscle. The second dose is administered within 1 month of the first one, and the third one within 6 months of the first. The vaccine is more than 95% effective. Only minor adverse reactions have been reported with vaccination, including transient fever and soreness at the injection site. The vaccine is not contraindicated in pregnancy.

The first dose of hepatitis B vaccine should be given at birth, with the vaccine series completed by age 6 to 18 months. Older children and adolescents who did not previously receive the hepatitis B vaccine should also be vaccinated.[13] It is also important to vaccinate adults in the at-risk groups discussed above. Household members of the patient with HBV should be tested

and vaccinated if they are HBsAg and antibody negative. Hepatitis vaccination is recommended for patients with chronic kidney disease before they start dialysis. Dialysis patients should routinely have their antibody titer levels checked to determine the need for revaccination.[13]

For postexposure prophylaxis, the HBV vaccine and hepatitis B immune globulin (HBIG) are used. HBIG contains antibodies to HBV and confers temporary passive immunity. HBIG is prepared from plasma of donors with a high titer of anti-HBs. HBIG is recommended for postexposure prophylaxis in cases of needle stick, mucous membrane contact, or sexual exposure and for infants born to mothers who are positive for HBsAg. Ideally HBIG should be given within 24 hours of exposure. The vaccine series should also be started.

According to Centers for Disease Control and Prevention (CDC) guidelines, follow infection control precautions for the patient with HBV. This includes using disposable needles and syringes and disposing of them in puncture-resistant units without recapping, bending, or breaking. (See eTable 15-1 on the website for that chapter for various types of infection control precautions.)

Hepatitis C. No vaccine is currently available for hepatitis C. The primary measures to prevent HCV transmission include screening of blood, organ, and tissue donors; use of infection control precautions; and modification of high-risk behavior. Identify individuals at high risk for contracting HCV and teach methods to reduce risks. Because of the number of people with hepatitis C who have not been diagnosed, the CDC recommends that all persons born between 1945 and 1965 undergo HCV testing regardless of risk factor status.[14] The CDC does not recommend IG or antiviral agents such as interferon for postexposure prophylaxis (e.g., needle-stick exposure from an infected patient) for HCV infection. After an acute exposure (e.g., needle stick), the person should have anti-HCV testing done. For the person exposed to HCV, baseline anti-HCV and ALT levels should be measured, with follow-up testing at 4 to 6 months. Testing for HCV RNA may be performed at 4 to 6 weeks.[15,16]

ACUTE INTERVENTION. In patients with hepatitis, assess for the presence and degree of jaundice. In light-skinned persons, jaundice is usually observed first in the sclera of the eyes and later in the skin. In dark-skinned persons, jaundice is observed in the hard palate of the mouth and inner canthus of the eyes. The urine may have a dark brown or brownish red color because of bilirubin. Comfort measures to relieve pruritus (if present), headache, and arthralgias are helpful (see eNursing Care Plan 44-1 on the website for this chapter).

Ensuring that the patient receives adequate nutrition is not always easy. The anorexia and distaste for food cause nutritional problems. Assess the patient's tolerance of specific foods and eating pattern. Small, frequent meals may be preferable to three large ones and may also help prevent nausea. Often a patient with hepatitis finds that anorexia is not as severe in the morning, so it is easier to eat a good breakfast than a large dinner. Measures to stimulate the appetite, such as mouth care, antiemetics, and attractively served meals in pleasant surroundings, should be included in your nursing care plan. Drinking carbonated beverages and avoiding very hot or very cold foods may help alleviate anorexia. Adequate fluid intake (2500 to 3000 mL/day) is important.

Rest is an important factor in promoting hepatocyte regeneration. Assess the patient's response to the rest and activity plan, and modify it accordingly. Liver function tests and symptoms are used as a guide to activity.

Psychologic and emotional rest is as essential as physical rest. Limited activity may produce anxiety and extreme restlessness in some patients. Diversional activities, such as reading and hobbies, may help.

AMBULATORY AND HOME CARE. Most patients with viral hepatitis are cared for at home, so you need to assess the patient's knowledge of nutrition and provide the necessary dietary teaching. Caution the patient about overexertion and the need to follow the health care provider's advice about when to return to work. Teach the patient and the caregiver how to prevent transmission to other family members. Also teach what symptoms should be reported to the health care provider.

Assess the patient for manifestations of complications. Bleeding tendencies with increasing prothrombin time values, symptoms of encephalopathy, or elevated liver function tests indicate problems.

Instruct the patient to have regular follow-up for at least 1 year after the diagnosis of hepatitis. Because relapses occur with hepatitis B and C, teach the patient the symptoms of recurrence and the need for follow-up evaluations. All patients with chronic HBV or HCV should avoid alcohol, since it can accelerate disease progression.

The patient who is receiving interferon for the treatment of HBV or HCV requires education regarding this drug. Because interferon is administered subcutaneously, the patient or the caregiver needs to be taught how to administer the drug. The numerous side effects with the therapy, including flu-like symptoms (e.g., fever, malaise, fatigue), make adherence to therapy challenging for some patients. Patients who are positive for HBsAg (chronic carrier status) or HCV antibody should not be blood donors.

EVALUATION

Expected outcomes are that the patient with hepatitis will

- Maintain food and fluid intake adequate to meet nutritional needs
- Demonstrate gradual increase in activity tolerance
- Perform daily activities with scheduled rest periods

Additional information on expected outcomes for the patient with hepatitis is provided in eNursing Care Plan 44-1 on the website for this chapter.

DRUG- AND CHEMICAL-INDUCED LIVER DISEASES

Alcohol consumption is a frequent cause of both acute and chronic liver disease. It can cause a spectrum of symptoms, ranging from mild elevation in liver enzymes (aspartate aminotransferase [AST] and ALT); to acute alcoholic hepatitis; to advanced fibrosis and cirrhosis, which usually occurs after decades of excessive alcohol intake. Patients may have serious liver disease caused by another chronic disease (e.g., chronic HCV infection) in combination with alcoholic liver disease.

Acute alcoholic hepatitis is a syndrome of enlarged liver (hepatomegaly), jaundice, elevation in liver enzyme tests (AST, ALT, alkaline phosphate), low-grade fever, and possibly ascites and prolonged prothrombin time. These symptoms may improve with cessation of alcohol intake.

Patients may have undetected liver disease and be seen with complications of cirrhosis. Even at this stage, abstinence can

result in significant reversal in some patients. If liver function does not recover after abstaining from alcohol for several months or longer, liver transplantation may be considered.

Chemical hepatotoxicity is due to systemic poisons (e.g., carbon tetrachloride, gold compounds). However, because of their declining use, the incidence of these reactions has declined since the 1980s.

Drug-induced liver injury (DILI) is one of the more common causes of jaundice.[17] Many medications (prescription, over-the-counter [OTC], and herbal supplements) can cause an increase in liver enzymes and, in severe cases, jaundice and acute liver failure. The pattern of injury depends on the drug causing the reaction. The most common cause of DILI is acetaminophen.

DRUG ALERT: Acetaminophen (Tylenol)

- Drug is safe if taken at recommended levels. However, its prevalence in a variety of pain relievers, fever reducers, and cough medicines may mean that patients do not realize they are taking several drugs that all contain acetaminophen.
- Many Americans each year experience acute liver failure as a result of taking acetaminophen. About 100 people die annually from overdosing, either intentionally or unintentionally.
- Combining the drug with alcoholic beverages increases the risk of liver damage.

AUTOIMMUNE, GENETIC, AND METABOLIC DISEASES

Autoimmune Hepatitis

Autoimmune hepatitis is a chronic inflammatory disorder of the liver of unknown cause. It is characterized by the presence of autoantibodies, high levels of serum immunoglobulins, and frequent association with other autoimmune diseases. The majority of patients with autoimmune hepatitis are women. Laboratory tests are used to distinguish it from other forms of hepatitis. Serologic markers are often useful in the diagnosis. These include antinuclear antibodies (ANAs) and anti-DNA antibodies.

The disease process involves an autoimmune reaction against normal hepatocytes. Although it can cause acute liver failure, the course of the disease is variable, with most patients developing chronic hepatitis. Untreated autoimmune hepatitis can progress to cirrhosis. Prednisone with or without azathioprine (Imuran) is the recommended treatment for active autoimmune hepatitis. Cyclosporine (Gengraf), tacrolimus (Prograf, FK506), budesonide (Entocort), methotrexate, and mycophenolate mofetil (CellCept) have also been used in patients who do not respond to prednisone and azathioprine.

Wilson's Disease

Wilson's disease is an autosomal recessive defect in cellular copper transport. A defect in biliary excretion leads to accumulation of copper in the liver, causing progressive liver injury and cirrhosis. Approximately one in 40,000 people have Wilson's disease. It affects both men and women equally. Symptoms appear between ages 5 and 35.[18]

Once cirrhosis occurs, copper leaks into the plasma; accumulates in and damages other tissues; and can cause neurologic, hematologic, and renal disease. The hallmark of Wilson's disease is corneal Kayser-Fleischer rings. These are brownish red rings that can be seen in the cornea near the limbus on eye examination. Low serum ceruloplasmin levels and measurable copper concentrations from liver biopsy samples are also present. Diagnosis is based on clinical findings, including the corneal rings and neurologic symptoms. First-degree relatives of patients with Wilson's disease should be screened for the disease.

The recommended initial treatment of symptomatic patients or those with active disease is with chelating agents such as D-penicillamine (Cuprimine) or trientine (Syprine), which promote the excretion of urinary copper. Zinc acetate (Galzin), which has also been used as therapy, interferes with the absorption of copper. Liver transplantation may be required in patients who develop cirrhosis.

Hemochromatosis

Hemochromatosis is an iron overload disorder. Although it is primarily caused by a genetic defect *(hereditary hemochromatosis),* it may also be caused by liver disease and chronic blood transfusions that are used to treat thalassemia and sickle cell disease. (Hemochromatosis is discussed in Chapter 31.)

Primary Biliary Cirrhosis

Primary biliary cirrhosis (PBC) is a chronic disease of the small bile ducts of the liver. In PBC, there is a T-cell–mediated attack of the small bile duct cells resulting in loss of bile ducts and ultimately *cholestasis* (blockage of bile flow). Over time, this leads to liver fibrosis and cirrhosis.

Most patients diagnosed with PBC are women between ages 30 and 65. The disease is associated with other autoimmune disorders such as rheumatoid arthritis, Sjögren's syndrome, and scleroderma. Elevated serum alkaline phosphatase levels, antimitochondrial antibodies (AMAs), ANAs, and serum lipid levels are seen in patients with PBC.

The goals of treatment are the suppression of ongoing liver damage, prevention of complications, and symptom management. The only approved drug for PBC is ursodeoxycholic acid (ursodiol [Actigall]). Management focuses on malabsorption, skin disorders such as pruritus and xanthomas (cholesterol deposits in the skin), hyperlipidemia, vitamin deficiencies, anemia, and fatigue. Cholestyramine (Questran) is used to treat pruritus. Patients are monitored for progression to cirrhosis. Liver transplantation is a treatment option for end-stage liver disease in patients with PBC.

Primary Sclerosing Cholangitis

Primary sclerosing cholangitis (PSC) is a disease of unknown etiology characterized by chronic inflammation, fibrosis, and strictures (narrowing) of the medium and large bile ducts. The majority of patients with PSC also have ulcerative colitis. Complications of PSC can include cholangitis, cholestasis with jaundice, cholangiocarcinoma (bile duct cancer), and cirrhosis.

Drug therapy has not been beneficial. Treatment is directed at reducing the incidence of biliary complications and screening for bile duct and colorectal cancer, which is related to the high incidence of ulcerative colitis. Patients with advanced liver disease may require liver transplantation.

Nonalcoholic Fatty Liver Disease and Nonalcoholic Steatohepatitis

Nonalcoholic fatty liver disease (NAFLD) refers to a wide spectrum of *liver diseases* ranging from a fatty liver (steatosis) to **nonalcoholic steatohepatitis (NASH)** to *cirrhosis*. In the spectrum of NAFLD, the common characteristic is the accumulation of fatty infiltration in the hepatocytes. In NASH the fat accumulation is associated with varying degrees of inflamma-

tion and fibrosis of the liver. NASH is a serious liver disease that can cause cirrhosis, hepatocellular cancer, and liver failure.

The term *nonalcoholic* is used because NAFLD and NASH occur in individuals who do not consume excessive amounts of alcohol. However, a pathologic analysis of liver cells in NAFLD is similar to that in alcoholic liver disease.

Currently, NAFLD affects about 10% to 20% of the U.S. population. This percentage is increasing because of the growing number of people who are obese. NAFLD should be considered in patients with risk factors such as obesity, diabetes, hyperlipidemia, and hypertension. NASH affects 2% to 5% of the U.S. population.[19] Elevations in liver function tests (ALT, AST) are often the first signs of NAFLD. Definitive diagnosis is by liver biopsy. Ultrasound and computed tomography (CT) scans are also used to diagnose NAFLD.

There is no definitive treatment, and therapy is directed at reduction of risk factors. This includes treatment of diabetes, reduction in body weight, and management of hyperlipidemia.

CIRRHOSIS

Cirrhosis is a chronic progressive disease of the liver characterized by extensive degeneration and destruction of the liver cells (Fig. 44-4). The development of cirrhosis is an insidious, prolonged course, usually after decades of chronic liver disease. Cirrhosis (combined with chronic liver diseases) ranks as the eighth leading cause of death in the United States. Cirrhosis is twice as common in men as in women.

Etiology and Pathophysiology

Any chronic liver disease, including disease from excessive alcohol intake and NAFLD, can cause cirrhosis. The specific cause of cirrhosis may not be determined in all patients. The most common causes of cirrhosis in the United States are chronic hepatitis C infection and alcohol-induced liver disease. In patients with alcohol-induced liver disease, some controversy exists as to whether the cause is the alcohol or the malnutrition that often coexists with alcoholism. A common problem in people who abuse alcohol is protein malnutrition. Some cases of nutrition-related cirrhosis have resulted from extreme dieting, malabsorption, and obesity. Environmental factors and genetic predisposition may also lead to the development of cirrhosis, regardless of dietary or alcohol intake.

Approximately 20% of patients with chronic hepatitis C and 10% to 20% of those with chronic hepatitis B develop cirrhosis.

FIG. 44-4 Cirrhosis that developed secondary to alcoholism. The characteristic diffuse nodularity of the surface is due to the combination of regeneration and scarring of the liver.

CULTURAL & ETHNIC HEALTH DISPARITIES

Liver, Pancreas, and Gallbladder Disorders

Hepatitis

- Hepatitis C has a higher incidence among African Americans and Hispanics than whites.
- Hepatitis B has a higher incidence among Asian Americans and African Americans than non-Hispanic whites.
- Deaths caused by viral hepatitis are more common in African Americans.

Cirrhosis

- Death from cirrhosis occurs more frequently among African Americans than in other ethnic groups.

Liver and Pancreatic Cancer

- Primary liver cancer has a higher incidence among African Americans, Asian Americans, and Alaska Natives than whites.
- Pancreatic cancer occurs more frequently among African Americans and Asian Americans than whites.

Gallbladder Disease

- Whites and Native Americans have a higher incidence of gallbladder disease than African Americans or Asian Americans.

Chronic inflammation and cell necrosis result in fibrosis and, ultimately, cirrhosis. Chronic hepatitis combined with alcohol ingestion is synergistic in accelerating liver damage.

Biliary causes of cirrhosis include primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC). Both are described earlier in this chapter on the facing page.

Cardiac cirrhosis includes a spectrum of hepatic derangements that result from long-standing, severe, right-sided heart failure. The treatment is aimed at managing the patient's underlying heart failure.

In cirrhosis the liver cells attempt to regenerate, but the regenerative process is disorganized, resulting in abnormal blood vessel and bile duct architecture. The overgrowth of new and fibrous connective tissue distorts the liver's normal lobular structure, resulting in lobules of irregular size and shape with impeded blood flow. Eventually, irregular and disorganized liver regeneration, poor cellular nutrition, and hypoxia (from inadequate blood flow and scar tissue) result in decreased functioning of the liver.

Clinical Manifestations

Early Manifestations. The onset of cirrhosis is usually insidious. Early symptoms include fatigue. Many patients with normal liver function (compensated cirrhosis) may not be aware of their liver condition. The diagnosis may not be discovered until later, when they manifest symptoms of more advanced liver disease.

Later Manifestations. Later symptoms may be severe and result from liver failure and portal hypertension (Fig. 44-5). Jaundice, peripheral edema, and ascites develop gradually. Other late symptoms include skin lesions, hematologic disorders, endocrine disturbances, and peripheral neuropathies (Fig. 44-6). In the advanced stages, the liver becomes small and nodular.

Jaundice. Jaundice results from the functional derangement of liver cells and compression of bile ducts by connective tissue overgrowth. Jaundice occurs as a result of the decreased ability to conjugate and excrete bilirubin (see Table 44-3). (Normal bilirubin metabolism is presented in Fig. 39-4.) The jaundice

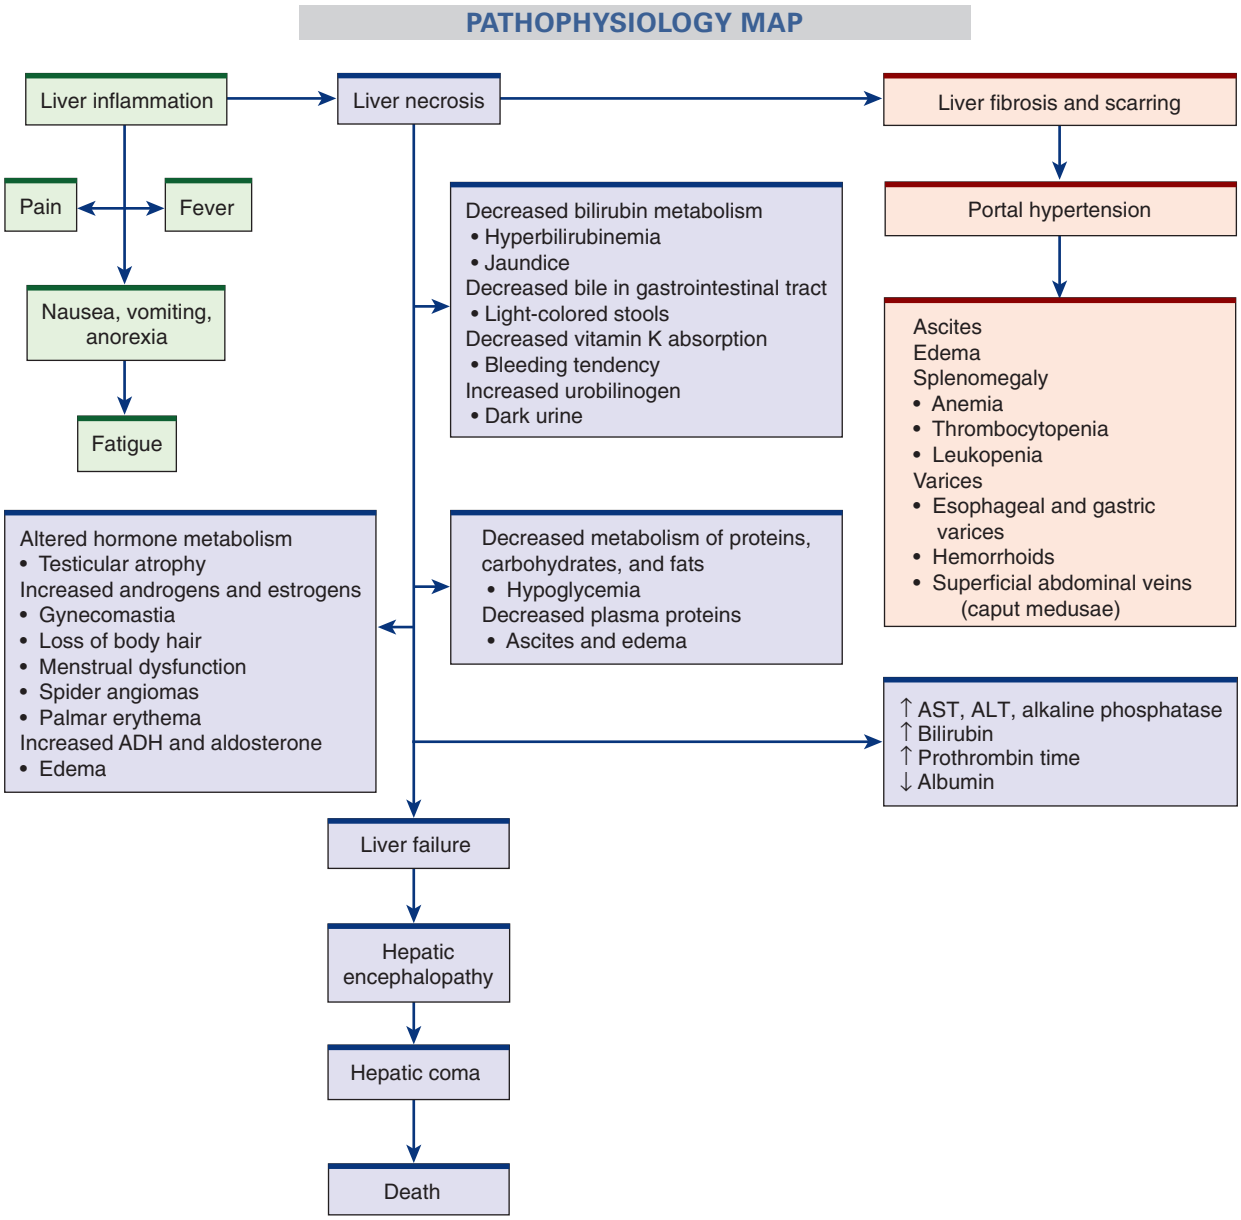

FIG. 44-5 Continuum of liver dysfunction in cirrhosis and resulting manifestations. *ADH,* Antidiuretic hormone; *ALT,* alanine aminotransferase; *AST,* aspartate aminotransferase.

may be minimal or severe, depending on the degree of liver damage.

Skin Lesions. Various skin manifestations are commonly seen in cirrhosis. **Spider angiomas** (*telangiectasia* or *spider nevi*) are small, dilated blood vessels with a bright red center point and spiderlike branches. They occur on the nose, cheeks, upper trunk, neck, and shoulders. *Palmar erythema* (a red area that blanches with pressure) is located on the palms of the hands. Both of these lesions are attributed to an increase in circulating estrogen as a result of the damaged liver's inability to metabolize steroid hormones.

Hematologic Problems. Hematologic problems include thrombocytopenia, leukopenia, anemia, and coagulation disorders. Thrombocytopenia, leukopenia, and anemia are probably caused by the splenomegaly that results from backup of blood from the portal vein into the spleen (portal hypertension). Overactivity of the enlarged spleen results in increased removal of blood cells from circulation. Anemia is also due to inadequate red blood cell (RBC) production and survival, poor diet, poor absorption of folic acid, and bleeding from varices.

The coagulation problems result from the liver's inability to produce prothrombin and other factors essential for blood clotting. Coagulation problems are manifested by hemorrhage or bleeding tendencies, such as epistaxis, purpura, petechiae, easy bruising, gingival bleeding, and heavy menstrual bleeding.

Endocrine Problems. Normally the liver is important in the metabolism of adrenocortical hormones, estrogen, and testosterone. In men with cirrhosis, gynecomastia (benign growth of the glandular tissue of the male breast), loss of axillary and pubic hair, testicular atrophy, and impotence with loss of libido may occur because of increased estrogen levels. Younger women with cirrhosis may develop amenorrhea, and older women may have vaginal bleeding. The liver fails to metabolize aldosterone

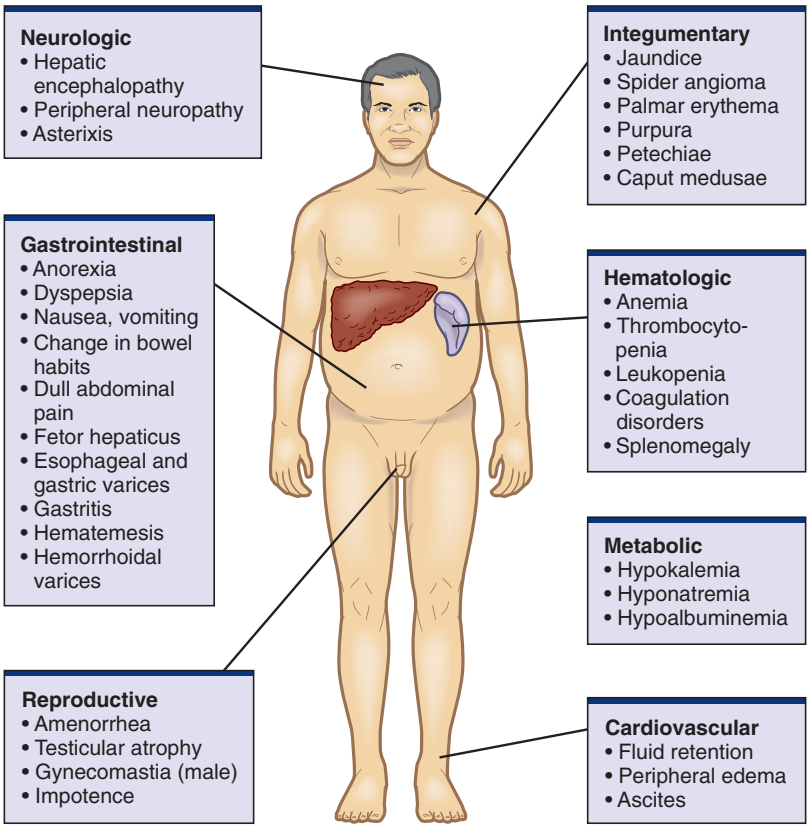

FIG. 44-6 Systemic clinical manifestations of liver cirrhosis.

adequately, resulting in hyperaldosteronism with subsequent sodium and water retention and potassium loss.

Peripheral Neuropathy. Peripheral neuropathy is a common finding in alcoholic cirrhosis and is probably due to a dietary deficiency of thiamine, folic acid, and cobalamin. The neuropathy usually results in mixed nervous system symptoms, but sensory symptoms may predominate.

Complications

Major complications of cirrhosis are portal hypertension with resultant esophageal and gastric varices, peripheral edema and ascites, hepatic encephalopathy (mental status changes, including coma), and hepatorenal syndrome. Patients without complications of cirrhosis have *compensated cirrhosis.* Those who have one or more complications of their liver disease have *decompensated cirrhosis*.

Portal Hypertension and Esophageal and Gastric Varices. Structural changes in the liver result in compression and destruction of the portal and hepatic veins and sinusoids. These changes cause obstruction to the normal flow of blood through the portal system, resulting in portal hypertension. **Portal hypertension** is characterized by increased venous pressure in the portal circulation, splenomegaly, large collateral veins, ascites, and gastric and esophageal varices. Collateral circulation develops in an attempt to reduce high portal pressure and the increased plasma volume and lymphatic flow. The collateral channels commonly form in the lower esophagus (the anastomosis of the left gastric vein and the azygos veins), anterior abdominal wall, parietal peritoneum, and rectum. Varicosities may develop in areas where the collateral and systemic circulations communicate, resulting in esophageal and gastric varices, *caput medusae* (ring of varices around the umbilicus), and hemorrhoids.

Esophageal varices are a complex of tortuous veins at the lower end of the esophagus, which are enlarged and swollen as a result of portal hypertension. **Gastric varices** are located in the upper portion (cardia, fundus) of the stomach. These varices contain little elastic tissue and are fragile. They tolerate high pressure poorly and, as a result, bleed easily. Large varices are more likely to bleed. Esophageal varices are responsible for approximately 80% of variceal hemorrhages. The remaining 20% of variceal hemorrhages are due to gastric varices.

Bleeding esophageal varices are the most life-threatening complication of cirrhosis. The patient may have melena or hematemesis. There may be slow oozing or massive hemorrhage. Massive hemorrhage is a medical emergency.

Peripheral Edema and Ascites. Peripheral edema sometimes precedes ascites, but in some patients its development coincides with or occurs after ascites. Edema results from decreased colloidal oncotic pressure from impaired liver synthesis of albumin and increased portacaval pressure from portal hypertension. Peripheral edema occurs as ankle and presacral edema.

Ascites is the accumulation of serous fluid in the peritoneal or abdominal cavity. It is a common manifestation of cirrhosis. With portal hypertension, proteins shift from the blood vessels via the larger pores of the sinusoids (capillaries) into the lymph space (Fig. 44-7). When the lymphatic system is unable to carry off the excess proteins and water, they leak through the liver capsule into the peritoneal cavity. The osmotic pressure of the proteins pulls additional fluid into the peritoneal cavity (Table 44-9).

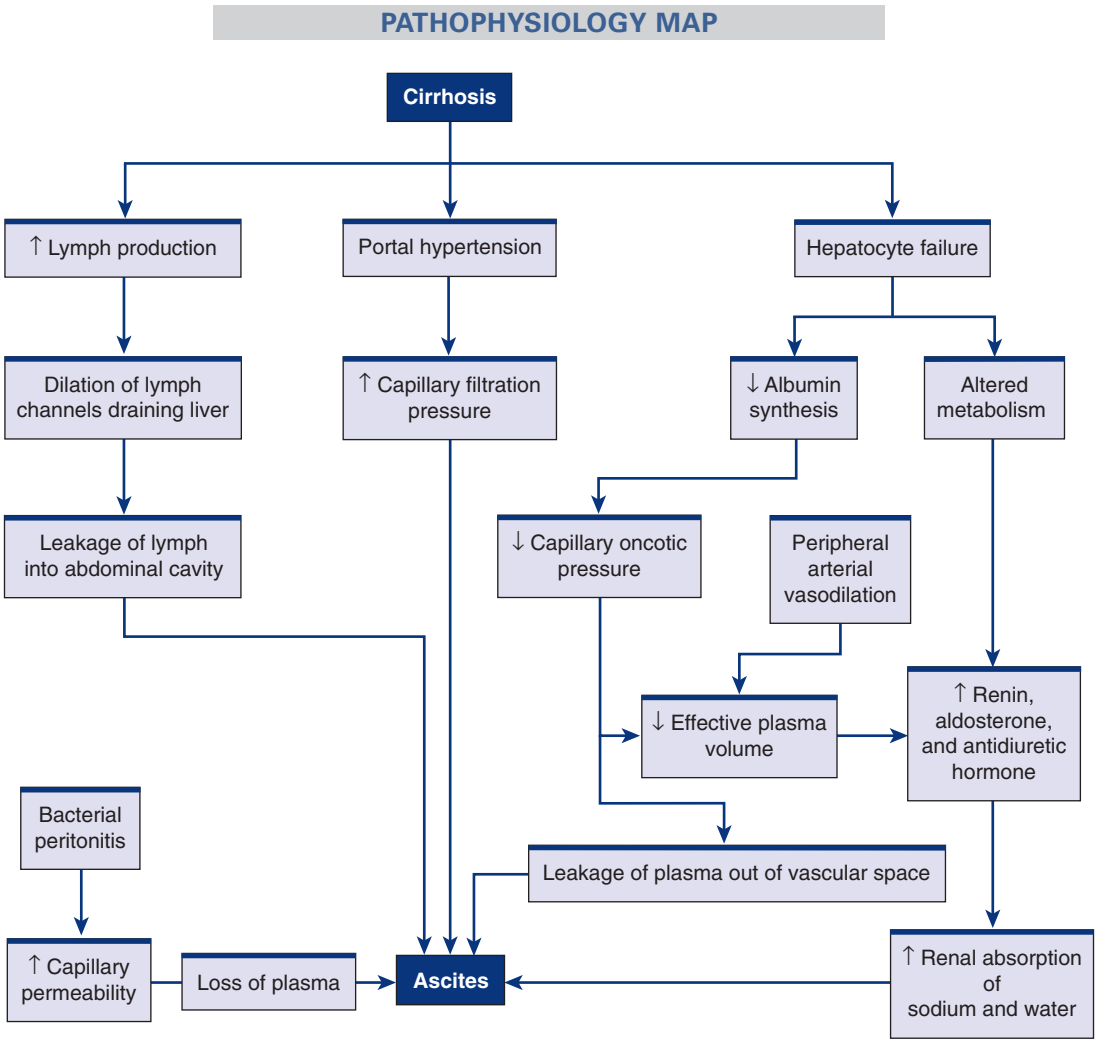

FIG. 44-7 Mechanisms for development of ascites.

TABLE 44-9 FACTORS INVOLVED IN ASCITES

Factor	Mechanism
Portal hypertension	Increase in resistance of blood flow through liver.
Increased flow of hepatic lymph	Leaking of protein-rich lymph from surface of cirrhotic liver. Intrahepatic blockage of lymph channels.
Decreased serum colloidal oncotic pressure	Impairment of liver synthesis of albumin. Loss of albumin into peritoneal cavity.
Hyperaldosteronism	Increase in aldosterone secretion stimulated by decreased renal blood flow. Decreased liver metabolism of aldosterone.
Impaired water excretion	Reduction in renal blood flow and high serum levels of antidiuretic hormone (ADH).

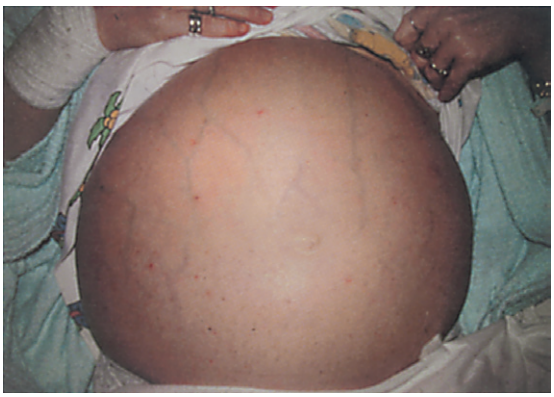

FIG. 44-8 Gross ascites.

A second mechanism of ascites formation is hypoalbuminemia resulting from the liver's inability to synthesize albumin. The hypoalbuminemia results in decreased colloidal oncotic pressure. A third mechanism is hyperaldosteronism, which occurs when aldosterone is not metabolized by damaged hepatocytes. The increased level of aldosterone causes increased sodium reabsorption by the renal tubules. This retention of sodium, combined with an increase in antidiuretic hormone, causes additional water retention. Because of edema formation, there is decreased intravascular volume and, subsequently, decreased renal blood flow and glomerular filtration.

Ascites is manifested by abdominal distention with weight gain (Fig. 44-8). If the ascites is severe, the umbilicus may be everted. Abdominal striae with distended abdominal wall veins may be present. The patient has signs of dehydration (e.g., dry tongue and skin, sunken eyeballs, muscle weakness) and a

decrease in urine output. Hypokalemia is common and is due to an excessive loss of potassium caused by hyperaldosteronism. Low potassium levels can also result from diuretic therapy used to treat the ascites.

Because of alterations in immune function associated with cirrhosis, patients with ascites are at risk for *spontaneous bacterial peritonitis* (SBP). SBP is a bacterial infection of the ascites fluid. This occurs in approximately 15% to 25% of hospitalized patients with cirrhosis and ascites and is particularly common after variceal hemorrhage.[20] The bacteria most frequently found are gram-negative enteric pathogens such as *Escherichia coli.*

Hepatic Encephalopathy. **Hepatic encephalopathy** is a neuropsychiatric manifestation of liver disease. The pathogenesis is multifactorial and includes the neurotoxic effects of ammonia, abnormal neurotransmission, astrocyte swelling, and inflammatory cytokines. A major source of ammonia is the bacterial and enzymatic deamination of amino acids in the intestines. The ammonia that results from this deamination process normally goes to the liver via the portal circulation and is converted to urea, which is then excreted by the kidneys. When blood is shunted past the liver via the collateral vessels or the liver is unable to convert ammonia to urea, the levels of ammonia in the systemic circulation increase. The ammonia crosses the blood-brain barrier and produces neurologic toxic manifestations. Factors that increase ammonia in the circulation may precipitate hepatic encephalopathy (Table 44-10).

TABLE 44-10 FACTORS PRECIPITATING HEPATIC ENCEPHALOPATHY

Factor	Mechanism
GI hemorrhage	Increase in ammonia in GI tract.
Constipation	Increase in ammonia from bacterial action on feces.
Hypokalemia	Potassium is needed by brain to metabolize ammonia.
Hypovolemia	Increase in blood ammonia because of hepatic hypoxia. Impairment of cerebral, hepatic, and renal function because of decreased blood flow.
Infection	Increase in catabolism and increase in cerebral sensitivity to toxins.
Cerebral depressants (e.g., opioids)	Decrease in metabolism by liver, causing higher drug levels and cerebral depression.
Metabolic alkalosis	Facilitation of transport of ammonia across blood-brain barrier. Increase in renal production of ammonia.
Paracentesis	Loss of sodium and potassium ions. Decrease in blood volume.
Dehydration	Potentiation of ammonia toxicity.
Increased metabolism	Increase in workload of liver.
Uremia (renal failure)	Retention of nitrogenous metabolites.

Hepatic encephalopathy can occur after placement of transjugular intrahepatic portosystemic shunt (TIPS), which is used to treat portal hypertension.[21]

Clinical manifestations of encephalopathy are changes in neurologic and mental responsiveness; impaired consciousness; and inappropriate behavior, ranging from sleep disturbances to lethargy to deep coma.[21] Changes may occur suddenly because of an increase in ammonia in response to bleeding varices or infection or gradually as blood ammonia levels slowly increase. A grading system is often used to classify the stages of hepatic encephalopathy (Table 44-11).

A characteristic manifestation of hepatic encephalopathy is **asterixis** (flapping tremors). This may take several forms, with the most common involving the arms and hands. When asked to hold the arms and hands stretched out, the patient is unable to hold this position and performs a series of rapid flexion and extension movements of the hands. Impairments in writing involve difficulty in moving the pen or pencil from left to right and *apraxia* (the inability to construct simple figures). Other signs include hyperventilation, hypothermia, and grimacing and grasping reflexes.

Fetor hepaticus (musty, sweet odor of the patient's breath) occurs in some patients with encephalopathy. This odor is from the accumulation of digestive by-products that the liver is unable to degrade.

Hepatorenal Syndrome. **Hepatorenal syndrome** can occur in patients with decompensated cirrhosis. It is a type of renal failure with advancing azotemia, oliguria, and intractable ascites. In this syndrome the kidneys have no structural abnormality. The etiology is complex, but the final common pathway is likely to be portal hypertension along with liver decompensation resulting in splanchnic and systemic vasodilation and decreased arterial blood volume. As a result, renal vasoconstriction occurs, and renal failure follows. This renal failure can be reversed by liver transplantation. In the patient with cirrhosis, hepatorenal syndrome frequently follows diuretic therapy, GI hemorrhage, or paracentesis.

Diagnostic Studies

Patients with cirrhosis have abnormalities in most of the liver function studies. Enzyme levels, including alkaline phosphatase, AST, ALT, and γ-glutamyl transpeptidase (GGT), are initially elevated because of their release from damaged liver cells. However, in end-stage liver disease AST and ALT levels may be normal. Patients with cirrhosis have decreased total protein, decreased albumin, increased serum bilirubin, and increased globulin levels. Fat metabolism abnormalities are reflected by decreased cholesterol levels. The prothrombin time is prolonged, and bilirubin metabolism is altered (see Table 44-3). A liver ultrasound may be used to assess the severity of cirrhosis. A liver biopsy may be done to identify liver cell changes and

TABLE 44-11 GRADING SCALE FOR HEPATIC ENCEPHALOPATHY

Grade	Level of Consciousness	Intellectual Function	Neurologic Findings
0	Insomnia, sleep disturbances	Subtle change in computational skills	Impaired handwriting, tremor
1	Lack of awareness, personality change	Short attention span, mild confusion, depression	Incoordination, asterixis
2	Lethargy, drowsiness, inappropriate behavior	Disoriented	Asterixis, abnormal reflexes
3	Asleep, rousable	Loss of meaningful conversation, marked confusion, incomprehensible speech	Asterixis, abnormal reflexes
4	Not rousable	Absent	Decerebrate May be responsive to painful stimuli

TABLE 44-12 COLLABORATIVE CARE

Cirrhosis of the Liver

Diagnostic
- History and physical examination
- Liver function studies
- Liver biopsy (percutaneous needle)
- Upper endoscopy (esophagogastroduodenoscopy)
- CT scan, multiphase
- Liver ultrasound (e.g., FibroScan for stiffness)
- Serum electrolytes
- Prothrombin time
- Serum albumin
- Complete blood count

Collaborative Therapy

Conservative Therapy
- Rest
- Administration of B-complex vitamins
- Avoidance of alcohol
- Minimization or avoidance of aspirin, acetaminophen, and NSAIDs

Ascites
- Low-sodium diet
- Diuretics
- Paracentesis (if indicated)

Esophageal and Gastric Varices
- Drug therapy
  - Nonselective β-blocker (e.g., propranolol [Inderal])
  - octreotide (Sandostatin)
  - vasopressin (Pitressin)
- Endoscopic band ligation or sclerotherapy
- Balloon tamponade
- Transjugular intrahepatic portosystemic shunt (TIPS)

Hepatic Encephalopathy
- Antibiotics (rifaximin [Xifaxan])
- lactulose (Cephulac)

alterations in the lobular structure. Differential analysis of ascitic fluid may help confirm the cause of cirrhosis.

Collaborative Care

The goal of treatment is to slow the progress of cirrhosis and prevent and treat any complications. Collaborative care measures are listed in Table 44-12. Management of specific problems associated with cirrhosis is described next.

Ascites. Management of ascites focuses on sodium restriction, diuretics, and fluid removal. The amount of sodium restriction is based on the degree of ascites. Initially the patient may be encouraged to limit sodium intake to 2 g/day.[22] Patients with severe ascites may need to restrict their sodium intake to 250 to 500 mg/day. Very low sodium intake can result in reduced nutritional intake and subsequent problems associated with malnutrition. The patient is usually not on restricted fluids unless severe ascites develops. Accurately assess and monitor fluid and electrolyte balance. Albumin infusion may be used to help maintain intravascular volume and adequate urine output by increasing plasma colloid osmotic pressure.

Diuretic therapy is an important part of management. Often a combination of drugs that work at multiple sites in the nephron is more effective. Spironolactone (Aldactone) is an effective diuretic, even in patients with severe sodium retention. Spironolactone is an antagonist of aldosterone and is potassium sparing. Other potassium-sparing diuretics include amiloride (Midamor) and triamterene (Dyrenium). A high-potency loop diuretic, such as furosemide (Lasix), is frequently used in combination with a potassium-sparing drug.

Tolvaptan (Samsca), a vasopressin-receptor antagonist, is used to correct hyponatremia in patients with cirrhosis. It causes an increase in water excretion, resulting in an increase in serum sodium concentrations.[23]

A **paracentesis** (needle puncture of the abdominal cavity) may be performed to remove ascitic fluid or to test the fluid for infection (spontaneous bacterial peritonitis). However, this procedure is reserved for the patient with impaired respiration or abdominal pain caused by severe ascites. It is only a temporary measure because the fluid tends to reaccumulate.

TIPS (discussed later in this section) is used to alleviate ascites that does not respond to diuretics. Peritoneovenous shunt is a surgical procedure that provides continuous reinfusion of ascitic fluid into the venous system. Its use has almost been eliminated because of the high rate of complications.

Esophageal and Gastric Varices. The main therapeutic goal for esophageal and gastric varices is to prevent bleeding and hemorrhage. The patient who has esophageal varices should avoid ingesting alcohol, aspirin, and nonsteroidal antiinflammatory drugs (NSAIDs).

All patients with cirrhosis should have an upper endoscopy (esophagogastroduodenoscopy [EGD]) to screen for varices. The diagnosis of esophageal or gastric variceal bleeding needs to be made by endoscopic examination as soon as possible. Patients with varices at risk of bleeding are started on a nonselective β-blocker (nadolol [Corgard] or propranolol [Inderal]) to reduce the incidence of hemorrhage. β-Blockers decrease high portal pressure.

When variceal bleeding occurs, the first step is to stabilize the patient and manage the airway. IV therapy is initiated and may include administration of blood products. Management that involves a combination of drug therapy and endoscopic therapy is more successful than either approach alone.

Drug therapy for bleeding varices may include the somatostatin analog octreotide (Sandostatin) or vasopressin (VP). The main goal of drug therapy is to stop bleeding so that treatment measures can be initiated. IV administration of VP produces vasoconstriction of the splanchnic arterial bed, decreases portal blood flow, and decreases portal hypertension. However, VP has many side effects, including decreased coronary blood flow, dysrhythmias, and increased BP. Because of this, IV nitroglycerin is often given in combination with VP. The nitroglycerin reduces the adverse effects of the VP while enhancing its beneficial effect. VP should be avoided or used cautiously in the older adult because of the risk of cardiac ischemia.

At the time of endoscopy, band ligation or sclerotherapy may be used to prevent rebleeding. Endoscopic variceal ligation (EVL, or "banding") is performed by placing a small rubber band (elastic O-ring) around the base of the *varix* (enlarged vein). Sclerotherapy involves injection of a sclerosant solution into the varices through an injection needle that is placed through the endoscope.

Balloon tamponade may be used in patients with acute esophageal or gastric variceal hemorrhage that cannot be controlled on initial endoscopy. Balloon tamponade controls the hemorrhage by mechanical compression of the varices. Different types of tubes are available. The Sengstaken-Blakemore tube

has two balloons, gastric and esophageal, with three lumens: one for the gastric balloon, one for the esophageal balloon, and one for gastric aspiration (see eFig. 44-1 on the website for this chapter). Two other types of balloons are the Minnesota tube (a modified Sengstaken-Blakemore tube with an esophageal suction port above the esophageal balloon) and the Linton-Nachlas tube.

SAFETY ALERT

- Label each lumen to avoid confusion.
- Deflate balloons for 5 min every 8-12 hr per institutional policy to prevent tissue necrosis.

Supportive measures during an acute variceal bleed include administration of fresh frozen plasma and packed RBCs, vitamin K, and proton pump inhibitors (e.g., pantoprazole [Protonix]). Lactulose (Cephulac) and rifaximin (Xifaxan) may be administered to prevent hepatic encephalopathy from breakdown of blood and the release of ammonia in the intestine. Antibiotics are given to prevent bacterial infection.

Because of the high incidence of recurrent bleeding with each bleeding episode, continued therapy is necessary. Long-term management of patients who have had an episode of bleeding includes nonselective β-blockers, repeated band ligation of the varices, and portosystemic shunts in patients who develop recurrent bleeding.

Shunting Procedures. Nonsurgical and surgical methods of shunting blood away from the varices are available. Shunting procedures tend to be used more after a second major bleeding episode than during an initial bleeding episode. *Transjugular intrahepatic portosystemic shunt (TIPS)* is a nonsurgical procedure in which a tract (shunt) between the systemic and portal venous systems is created to redirect portal blood flow (see eFig. 44-2 on the website for this chapter). A catheter is placed in the jugular vein and then threaded through the superior and inferior vena cava to the hepatic vein. The wall of the hepatic vein is punctured, and the catheter is directed to the portal vein. Stents are positioned along the passageway, overlapping in the liver tissue and extending into both veins.

This procedure reduces portal venous pressure and decompresses the varices, thus controlling bleeding. TIPS does not interfere with a future liver transplantation. Limitations of the procedure include the increased risk of hepatic encephalopathy and stenosis of the stent. TIPS is contraindicated in patients with severe hepatic encephalopathy, hepatocellular carcinoma, severe hepatorenal syndrome, and portal vein thrombosis.

Various surgical shunting procedures may be used to decrease portal hypertension by diverting some of the portal blood flow while allowing adequate liver perfusion. Currently, the surgical shunts most commonly used are the portacaval shunt and the distal splenorenal shunt (Fig. 44-9).

Hepatic Encephalopathy. The goal of management of hepatic encephalopathy is the reduction of ammonia formation. Ammonia formation in the intestines is reduced with lactulose, a drug that traps ammonia in the gut. It can be given orally, as an enema, or through a nasogastric (NG) tube. The laxative effect of the drug expels the ammonia from the colon. Antibiotics such as rifaximin may also be given, particularly in patients who do not respond to lactulose. Constipation should be prevented.

Control of hepatic encephalopathy also involves treatment of precipitating causes (see Table 44-10). This includes controlling GI bleeding and removing the blood from the GI tract to decrease the protein in the intestine.

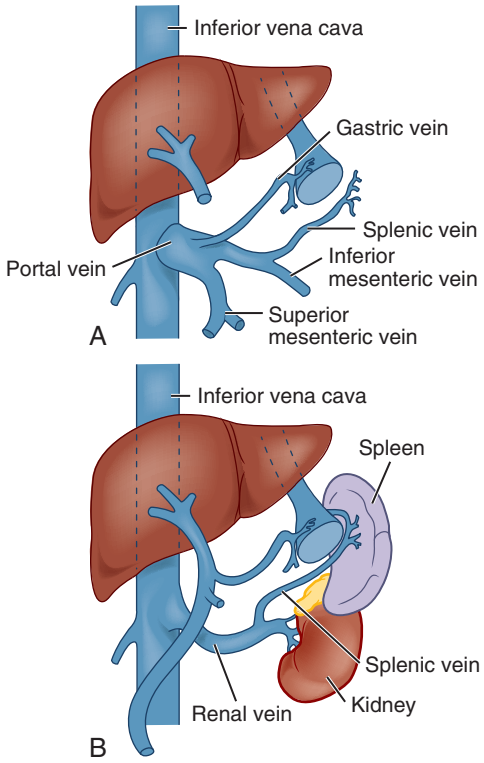

FIG. 44-9 Portosystemic shunts. **A,** Portacaval shunt. The portal vein is anastomosed to the inferior vena cava, diverting blood from the portal vein to the systemic circulation. **B,** Distal splenorenal shunt. The splenic vein is anastomosed to the renal vein. The portal venous flow remains intact while esophageal varices are selectively decompressed. (The short gastric veins are decompressed.) The spleen conducts blood from the high pressure of the esophageal and gastric varices to the low-pressure renal vein.

Drug Therapy. There is no specific drug therapy for cirrhosis. However, a number of drugs are used to treat symptoms and complications of advanced liver disease (Table 44-13).

Nutritional Therapy. The diet for the patient who has cirrhosis without complications is high in calories (3000 cal/day) with high carbohydrate content and moderate to low levels of fat. Protein restriction may be appropriate in some patients immediately after a severe flare of symptoms (i.e., episodic hepatic encephalopathy). However, protein restriction is rarely justified in patients with cirrhosis and persistent hepatic encephalopathy. Malnutrition is a more serious clinical problem than hepatic encephalopathy for many of these patients.[24]

A patient with alcoholic cirrhosis frequently has protein-calorie malnutrition. Enteral formula supplements containing protein from branched-chain amino acids that are metabolized by the muscles may be recommended. These supplements provide protein that is more easily metabolized by the liver. Parenteral nutrition or enteral nutrition therapy may be required.

The patient with ascites and edema is on a low-sodium diet. The degree of sodium restriction depends on the patient's condition. The patient needs instruction regarding the degree of restriction. Table salt is a well-known source of sodium, but sodium is also present in baking soda and baking powder. Foods that are high in sodium content include canned soups and vegetables, many frozen foods, salted snacks (e.g., potato chips), nuts, smoked meats and fish, crackers, breads, olives, pickles, ketchup, and beer. Advise the patient to read labels. The patient and the caregiver may need assistance in making the diet

TABLE 44-13 DRUG THERAPY

Cirrhosis

Drug	Mechanism of Action
vasopressin (Pitressin) octreotide (Sandostatin)	Hemostasis and control of bleeding in esophageal and gastric varices, constriction of splanchnic arterial bed
propranolol (Inderal) nadolol (Corgard)	Reduction of portal venous pressure, reduction of esophageal varices bleeding
lactulose (Cephulac)	Acidification of feces in bowel and trapping of ammonia, causing its elimination in feces
rifaximin (Xifaxan) neomycin sulfate	Decrease in bacterial flora, decreased formation of ammonia
magnesium sulfate	Magnesium replacement, hypomagnesemia possible with liver dysfunction
Vitamin K	Correction of clotting abnormalities from decreased levels of this vitamin
Proton pump inhibitors (e.g., pantoprazole [Protonix])	Decrease in gastric acidity
Diuretics	
• spironolactone (Aldactone)	Blocks action of aldosterone, potassium sparing
• furosemide (Lasix)	Acts on distal tubule and loop of Henle to decrease reabsorption of sodium and water

more palatable by using seasonings such as garlic, parsley, onion, lemon juice, and spices.

NURSING MANAGEMENT CIRRHOSIS

NURSING ASSESSMENT

Subjective and objective data that should be obtained from an individual with cirrhosis are presented in Table 44-14.

NURSING DIAGNOSES

Nursing diagnoses for the patient with cirrhosis include, but are not limited to, the following:

- Imbalanced nutrition: less than body requirements *related to* anorexia, nausea, and impaired utilization and storage of nutrients
- Impaired skin integrity *related to* peripheral edema, ascites, and pruritus
- Excess fluid volume *related to* portal hypertension and hyperaldosteronism
- Ineffective self-health management *related to* ineffective coping and abuse of alcohol

Additional information on nursing diagnoses for the patient with cirrhosis is presented in eNursing Care Plan 44-2 (available on the website for this chapter).

PLANNING

The overall goals are that the patient with cirrhosis will (1) have relief of discomfort, (2) have minimal to no complications (ascites, esophageal varices, hepatic encephalopathy), and (3) return to as normal a lifestyle as possible.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Common risk factors for cirrhosis include alcoholism, malnutrition, viral hepatitis, biliary obstruction, obesity, and right-sided heart failure. Prevention and early treatment of cirrhosis focus on reducing or eliminating these risk factors. Alcoholism must be treated. Urge patients to avoid alcohol ingestion, and support their efforts. (The treatment of alcohol dependence is discussed in Chapter 11.)

Adequate nutrition, especially for the alcoholic and other individuals at risk for cirrhosis, is essential to promote liver regeneration. Identify and treat acute hepatitis early so that it does not progress to chronic hepatitis and cirrhosis. Bariatric surgery for morbidly obese individuals has been shown to reduce the incidence of liver disease.[25]

ACUTE INTERVENTION. Nursing care for the patient with cirrhosis focuses on conserving the patient's strength while maintaining muscle strength and tone (see eNursing Care Plan 44-2 on the website for this chapter). When the patient requires complete bed rest, implement measures to prevent pneumonia, thromboembolic problems, and pressure ulcers. Modify the

TABLE 44-14 NURSING ASSESSMENT

Cirrhosis

Subjective Data

Important Health Information

Past health history: Previous viral, toxic, or idiopathic hepatitis; NASH, chronic biliary obstruction and infection; severe right-sided heart failure

Medications: Adverse reaction to any medication; use of anticoagulants, aspirin, NSAIDs, acetaminophen

Functional Health Patterns

Health perception–health management: Chronic alcoholism; weakness, fatigue

Nutritional-metabolic: Anorexia, weight loss, dyspepsia, nausea and vomiting; gingival bleeding

Elimination: Dark urine, decreased urine output; light-colored or black stools, flatulence, change in bowel habits; dry, yellow skin, bruising

Cognitive-perceptual: Dull, right upper quadrant or epigastric pain; numbness, tingling of extremities; pruritus

Sexuality-reproductive: Impotence, amenorrhea

Objective Data

General

Fever, cachexia, wasting of extremities

Integumentary

Icteric sclera, jaundice, petechiae, ecchymoses, spider angiomas, palmar erythema, alopecia, loss of axillary and pubic hair, peripheral edema

Respiratory

Shallow, rapid respirations, epistaxis

Gastrointestinal

Abdominal distention, ascites, distended abdominal wall veins, palpable liver and spleen, foul breath; hematemesis; black, tarry stools; hemorrhoids

Neurologic

Altered mentation, asterixis

Reproductive

Gynecomastia and testicular atrophy (men), impotence (men), loss of libido (men and women), amenorrhea or heavy menstrual bleeding (women)

Possible Diagnostic Findings

Anemia, thrombocytopenia; leukopenia; ↓ serum albumin, potassium; abnormal liver function studies; ↑ INR, ↓ platelets, ↑ ammonia, and ↑ bilirubin levels; abnormal abdominal ultrasound or MRI

INR, International normalized ratio; *NASH,* nonalcoholic steatohepatitis.

activity and rest schedule according to signs of clinical improvement (e.g., decreasing jaundice, improvement in liver function studies).

Anorexia, nausea and vomiting, pressure from ascites, and poor eating habits all interfere with adequate intake of nutrients. Oral hygiene before meals may improve the patient's taste sensation. Make between-meal snacks available so the patient can eat them at times when he or she can best tolerate them. Provide food preferences whenever possible. Explain the reason for any dietary restrictions to the patient and caregiver.

Nursing assessment and care should include the patient's physiologic response to cirrhosis. Is jaundice present? Where is it observed—sclera, skin, hard palate? What is the progression of jaundice? If the jaundice is accompanied by pruritus, carry out measures to relieve itching. Cholestyramine or hydroxyzine (Atarax) may be ordered to help relieve the pruritus. Other measures to alleviate pruritus include baking soda or Alpha Keri baths, lotions containing calamine, antihistamines, soft or old linens, and control of the temperature (not too hot and not too cold). Keep the patient's nails short and clean. Teach patients to rub with their knuckles rather than scratch with their nails when they cannot resist scratching.

Note the color of urine and stools. When jaundice is present, the urine is often dark brown and foamy when shaken. The stool is gray or tan.

Edema and ascites are frequent manifestations of cirrhosis and require nursing assessments and interventions. Accurate calculation and recording of intake and output, daily weights, and measurements of extremities and abdominal girth help in the ongoing assessment of the location and extent of the edema. Mark the abdomen with a permanent marker so the girth is measured at the same location each time.

Immediately before a paracentesis have the patient void to prevent a puncture of the bladder. When a paracentesis is done, the patient sits on the side of the bed or is placed in high Fowler's position. After the procedure, monitor for hypovolemia and electrolyte imbalances and check the dressing for bleeding and leakage.

Dyspnea is a frequent problem for the patient with severe ascites and can lead to pleural effusions. A semi-Fowler's or Fowler's position allows for maximal respiratory efficiency. Use pillows to support the arms and chest to increase the patient's comfort and ability to breathe.

Meticulous skin care is essential because the edematous tissues are subject to breakdown. Use an alternating-air pressure mattress or other special mattress. A turning schedule (minimum of every 2 hours) must be adhered to rigidly. Support the abdomen with pillows. If the abdomen is taut, cleanse it gently. The patient tends to move little because of abdominal discomfort and dyspnea. Range-of-motion exercises are helpful. Implement measures such as coughing and deep breathing to prevent respiratory problems. The lower extremities may be elevated. If scrotal edema is present, a scrotal support provides some comfort.

When the patient is taking diuretics, monitor the serum levels of sodium, potassium, chloride, and bicarbonate. Monitor renal function (blood urea nitrogen [BUN], serum creatinine) routinely and with any change in the diuretic dosage. Observe for signs of fluid and electrolyte imbalance, especially hypokalemia. Hypokalemia may be manifested by cardiac dysrhythmias, hypotension, tachycardia, and generalized muscle weakness. Water excess is manifested by muscle cramping, weakness, lethargy, and confusion.

Observe for and provide nursing care for any hematologic problems (bleeding tendencies, anemia, increased susceptibility to infection) (see eNursing Care Plan 44-2 on the website for this chapter).

Assess the patient's response to altered body image resulting from jaundice, spider angiomas, palmar erythema, ascites, and gynecomastia. The patient may experience anxiety and embarrassment about these changes. Explain these phenomena and be a supportive listener. Provide nursing care with concern and warmth to help the patient maintain self-esteem.

Bleeding Varices. If the patient has esophageal or gastric varices, observe for any signs of bleeding from the varices, such as hematemesis and melena. If hematemesis occurs, assess the patient for hemorrhage, call the physician, and be ready to assist with treatment used to control the bleeding. The patient will be admitted to the intensive care unit (ICU). The patient's airway must be maintained.

Balloon tamponade may be used in patients who have bleeding that is unresponsive to band ligation or sclerotherapy. When balloon tamponade is used, the initial nursing task is to explain the use of the tube and how it will be inserted. Check the balloons for patency. It is usually the physician's responsibility to insert the tube by either the nose or the mouth (see eFig. 44-1). Then the gastric balloon is inflated with approximately 250 mL of air, and the tube is retracted until resistance (lower esophageal sphincter) is felt. The tube is secured by placement of a piece of sponge or foam rubber at the nostrils (nasal cuff). For continued bleeding, the esophageal balloon is then inflated. A sphygmomanometer is used to measure and maintain the

ETHICAL/LEGAL DILEMMAS

Rationing

Situation

T.H., a 43-yr-old patient with cirrhosis of the liver, is frequently admitted to the hospital. She has been told that her continued drinking will inevitably lead to her death. Now she has been admitted for gastrointestinal bleeding and needs blood transfusions. She has a rare blood type, and it is frequently difficult to get compatible blood. Should you call an ethics consultation?

Ethical/Legal Points for Consideration

- *Rationing,* or the controlled distribution of scarce resources, is a difficult ethical problem. The needs of an individual patient or group of patients are weighed against the needs of many patients, who may have a greater chance of recovery, and the availability of the needed resources.
- Health interests can supercede the interests or rights of an individual. For example, in anticipation of an anthrax attack, the government could confiscate all relevant antibiotics and restrict their use to treatment of the disease.
- Two individual rights that must be considered with regard to rationing are the constitutional right to privacy and the right to consent to or refuse medical procedures and therapy.
- The competent adult is the only person who may consent to or refuse treatment for his or her health care problems.
- In the situation of T.H., if she consents to a blood transfusion, the ability of an intervening party to refuse that treatment would be permitted only given substantial intervening circumstances, and not as a threat to compel compliant behavior in the future.

Discussion Questions

1. What are your feelings about patients with diseases, such as substance abuse, that have a behavioral component? Do these patients deserve aggressive treatment?
2. How would you proceed to make a decision in T.H.'s case? Would you request an ethics committee consultation?

EVIDENCE-BASED PRACTICE

Applying the Evidence

You have been assigned to care for M.K., a 58-yr-old Hispanic man, who is being admitted with alcohol-related cirrhosis. As a part of his admission assessment, you ask about his current use of alcohol. He tells you that he has been "drinking more" since he lost his job. His admission blood alcohol concentration was 295 mg/dL. You ask if he has ever tried to stop drinking. He tells you many times, but "it never lasts." When asked if he has ever been to Alcoholics Anonymous (AA), he states that that "scene" is not for him. M.K. tells you that he knows he will not live very long and he sees no reason to stop drinking at this point.

Best Available Evidence	Clinician Expertise	Patient Preferences and Values
Although treatment strategies for alcohol dependency include inpatient and outpatient treatment programs for the individual, often they are not effective. Another approach is family therapy, which has been shown to decrease the incidence of alcohol-related disease and inpatient hospital stays.	Abstinence from the use of alcohol is critical in the treatment of cirrhosis. You have known many patients who have attended AA and are "recovering alcoholics." You also know that the family is an essential part of the effectiveness of treatment. You ask M.K. if you could meet with him and his family to discuss treatment options.	M.K. is not motivated to consider any treatment approaches for alcohol dependency. M.K. prefers to continue to use alcohol and he tells you that he knows the consequences.

Your Decision and Action

You acknowledge M.K.'s comments about his continued use of alcohol at this time but reassess his decision throughout his hospitalization. You also plan a meeting with key family members to discuss the issue. Based on the results of meeting with the family, you will try to set up a meeting with M.K., the family, and an appropriate therapist.

Reference for Evidence

Meads C, Ting S, Dretzke J, et al: A systematic review of the clinical and cost-effectiveness of psychological therapy involving family and friends in alcohol misuse or dependence, *Database Abstracts Rev Effects* 3, 2012.

desired pressure at 20 to 40 mm Hg. The position of the balloons is verified by x-ray.

Nursing care includes monitoring for complications of rupture or erosion of the esophagus, regurgitation and aspiration of gastric contents, and occlusion of the airway by the balloon. If the gastric balloon breaks or is deflated, the esophageal balloon will slip upward, obstructing the airway and causing asphyxiation. If this happens, cut the tube or deflate the esophageal balloon. Keep scissors at the bedside. Minimize regurgitation by oral and pharyngeal suctioning and by keeping the patient in a semi-Fowler's position.

The patient is unable to swallow saliva because of the inflated esophageal balloon occluding the esophagus. Encourage the patient to expectorate, and provide an emesis basin and tissues. Frequent oral and nasal care provides relief from the taste of blood and irritation from mouth breathing.

Hepatic Encephalopathy. Nursing care of the patient with hepatic encephalopathy focuses on maintaining a safe environment, sustaining life, and assisting with measures to reduce the formation of ammonia. Assess (1) the patient's level of responsiveness (e.g., reflexes, pupillary reactions, orientation), (2) sensory and motor abnormalities (e.g., hyperreflexia, asterixis, motor coordination), (3) fluid and electrolyte imbalances, (4) acid-base imbalances, and (5) the effect of treatment measures.

Assess the neurologic status, including an exact description of the patient's behavior, at least every 2 hours. Plan your care of the patient with neurologic problems based on the severity of the encephalopathy.

Institute measures to prevent constipation to reduce ammonia production. Give drugs, laxatives, and enemas as ordered. Encourage fluids, if not contraindicated. Any GI bleeding may worsen encephalopathy. Assess the patient taking lactulose for diarrhea and excessive fluid and electrolyte losses.

Control factors known to precipitate encephalopathy as much as possible, including anything that may cause constipation (e.g., dehydration, opioid medications).

AMBULATORY AND HOME CARE. The patient with cirrhosis may be faced with a prolonged course and the possibility of life-threatening problems and complications. The patient and caregiver need to understand the importance of continual health care and medical supervision. Supportive measures include proper diet, rest, avoidance of potentially hepatotoxic OTC drugs such as acetaminophen, and abstinence from alcohol.[25] Abstinence from alcohol is important and results in improvement in most patients. However, some patients find abstinence difficult. Explore your own attitude regarding the patient whose cirrhosis is attributed to alcohol abuse. Provide care without rejection or moralizing. Treat the patient with a caring attitude (see Chapter 11).

Cirrhosis is a chronic disease. The patient is affected not only physically but also psychologically, socially, and economically. Major lifestyle changes may be required, especially if alcohol abuse is the primary etiologic factor. Provide information regarding community support programs, such as Alcoholics Anonymous, for help with alcohol abuse.

When you know a patient's diagnosis is cirrhosis, do not assume the cause is excess alcohol intake. Because cirrhosis has many different causes, it is important for you to find out the primary etiology before jumping to conclusions about the patient.

Teach the patient and caregiver about manifestations of complications and when to seek medical attention. Explain both verbally and in writing information about fluid or possible dietary changes (Table 44-15). Include instructions about adequate rest periods, how to detect early signs of complications, skin care, drug therapy precautions, observation for bleeding, and protection from infection. Counseling information regarding sexual problems may be needed. Referral to a community or home health nurse may be helpful to ensure patient adherence to prescribed therapy. Home care for the patient with cirrhosis should emphasize helping the patient maintain the highest level of wellness possible and initiate and maintain necessary lifestyle changes.

EVALUATION

Expected outcomes are that the patient with cirrhosis will

- Maintain food and fluid intake adequate to meet nutritional needs
- Maintain skin integrity with relief of edema and pruritus
- Experience normalization of fluid balance as a result of medical and nursing interventions
- Acknowledge and get treatment for a substance abuse problem

TABLE 44-15 PATIENT & CAREGIVER TEACHING GUIDE

Cirrhosis

When teaching the patient and caregiver about management of cirrhosis, do the following.

1. Explain that cirrhosis is a chronic illness and the importance of continual health care.
2. Teach the symptoms of complications and when to seek medical attention to enable prompt treatment of complications.
3. Teach the patient to avoid potentially hepatotoxic over-the-counter drugs (see Table 39-6) because the diseased liver is unable to metabolize these drugs.
4. Encourage abstinence from alcohol because continued use of alcohol will increase the risk of liver complications.
5. Instruct the patient to avoid aspirin and NSAIDs to prevent hemorrhage when esophageal or gastric varices are present.
6. Teach the patient to avoid activities that increase portal pressure, such as straining at stool, coughing, sneezing, and retching and vomiting. These activities may increase the risk of variceal hemorrhage in patients with portal hypertension and varices.

Additional information on expected outcomes for the patient with cirrhosis is presented in eNursing Care Plan 44-2 (available on the website for this chapter).

ACUTE LIVER FAILURE

Acute liver failure, or *fulminant hepatic failure,* is a clinical syndrome characterized by severe impairment of liver function associated with hepatic encephalopathy. The most common cause is drugs, usually acetaminophen in combination with alcohol.[26] People who abuse alcohol are particularly susceptible to detrimental effects of acetaminophen on the liver. Other drugs that can cause acute liver failure include isoniazid, halothane, sulfa-containing drugs, and NSAIDs. Drugs can cause liver cell failure by disrupting essential intracellular processes or causing an accumulation of toxic metabolic products.

Viral hepatitis, in particular HBV, is the second most common cause of acute liver failure. Hepatitis A is a less common cause.

Acute liver failure is characterized by the rapid onset of severe liver dysfunction in someone with no prior history of liver disease. Although the disease can run its course over 8 weeks, it can last as long as 26 weeks. With improved intensive care, the prognosis is much better now than in the past, with survival rates of approximately 60%.[27]

Clinical Manifestations and Diagnostic Studies

Manifestations include jaundice, coagulation abnormalities, and encephalopathy. In acute liver failure, changes in mentation are the first clinical sign. Patients are susceptible to a wide variety of complications, including cerebral edema, renal failure, hypoglycemia, metabolic acidosis, sepsis, and multiorgan failure.

Serum bilirubin is elevated, and the prothrombin time is prolonged. Liver enzyme levels (AST, ALT) are often markedly elevated. Additional laboratory tests include blood chemistries (especially glucose, since hypoglycemia may be present and require correction), complete blood counts (CBCs), acetaminophen level and screening for other drugs and toxins, viral hepatitis serologies (especially HAV and HBV), serum ceruloplasmin (enzyme synthesized in liver) levels, α_1-antitrypsin levels, iron levels, and autoantibodies (antinuclear and anti–smooth muscle antibodies). Plasma ammonia levels may also be obtained.

CT or magnetic resonance imaging (MRI) is helpful in providing information about the liver size and contour, presence of ascites, tumors, and patency of the blood vessels.

NURSING AND COLLABORATIVE MANAGEMENT ACUTE LIVER FAILURE

Since acute liver failure may progress rapidly, with hour-by-hour changes in consciousness, early transfer to the ICU is preferred once the diagnosis is made. Planning for transfer to a transplant center should begin in patients with grade 1 or 2 encephalopathy because they may worsen rapidly. Early transfer is important because the risks involved with patient transport may increase or even preclude transfer once stage 3 or 4 encephalopathy develops (see Table 44-11).

Renal failure is a frequent complication in patients with liver failure and may be due to dehydration, hepatorenal syndrome, or acute tubular necrosis. The frequency of renal failure may be even greater with acetaminophen overdose or other toxins, where direct renal toxicity occurs. Although few patients die of renal failure alone, it often increases the mortality risk and may worsen the prognosis. Protect renal function by maintaining adequate fluid balance, avoiding nephrotoxic agents (e.g., aminoglycosides, NSAIDs), and promptly identifying and treating infection.

Liver transplantation is the treatment of choice for and increases survival rates in patients with acute liver failure. Cerebral edema, cerebellar herniation, and brainstem compression are the most common causes of death. Treatment of cerebral edema is described in Chapter 57. Monitoring and management of hemodynamic and renal function, as well as glucose, electrolytes, and acid-base status, are critical. Conduct frequent neurologic evaluations for signs of elevated intracranial pressure. Position the patient with the head elevated at 30 degrees. Avoid patient stimulation. Maneuvers that cause straining or Valsalva-like movements may increase intracranial pressure (ICP).

Avoid the use of any sedatives because of their effects on mental status. Only minimal doses of benzodiazepines should be used due to their delayed metabolism by the failing liver. ICP monitoring is discussed in Chapter 57. Additional measures include padding bedrails to avoid injury from possible seizures, closely observing the patient to prevent injuries, monitoring intake and output for renal function, and providing good skin and oral care to avoid breakdown and infection.

Alterations in level of consciousness may compromise nutritional intake. Factors such as coagulation problems may influence whether enteral nutrition is initiated. An NG tube may be irritating to the nasal and esophageal mucosa, thus causing bleeding.[28]

LIVER CANCER (HEPATOCELLULAR CANCER)

Primary liver cancer (hepatocellular carcinoma [HCC] or malignant hepatoma) is the fifth most common cancer and second most common cause of cancer death worldwide.[29] It is the most common cause of death in patients with cirrhosis. The incidence of HCC is rising in the United States because of the large number of patients infected with chronic hepatitis C. Cirrhosis caused by hepatitis C is the most common cause of HCC in the United States, followed by alcoholic cirrhosis.[30] Other

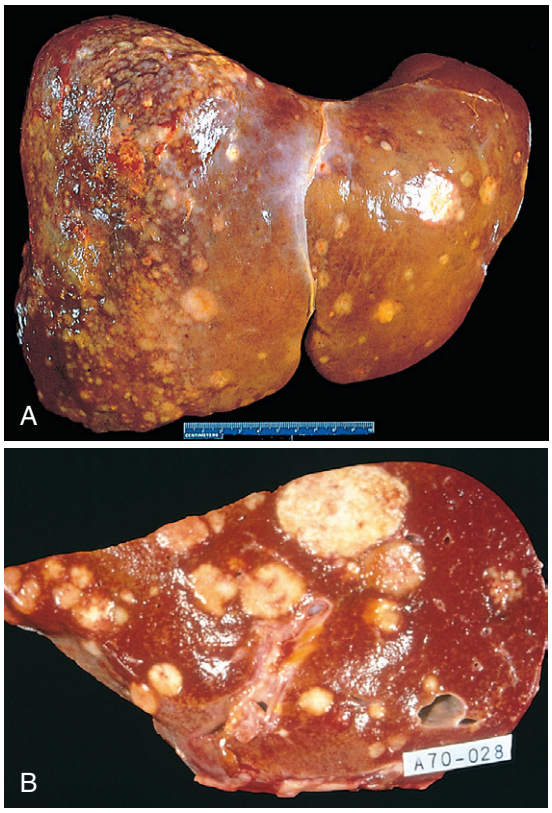

FIG. 44-10 Multiple hepatic metastases from a primary colon cancer. **A,** Gross specimen showing outside of liver. **B,** Liver section showing metastatic lesions.

primary liver tumors are cholangiomas or bile duct cancers (cholangiocarcinoma).

Metastatic carcinoma of the liver is more common than primary carcinoma (Fig. 44-10). The liver is a common site of metastatic growth because of its high rate of blood flow and extensive capillary network. Cancer cells in other parts of the body are commonly carried to the liver via the portal circulation.

In liver cancer, lesions may be singular or numerous and nodular or diffusely spread over the entire liver. Some tumors infiltrate other organs such as the gallbladder or move into the peritoneum or the diaphragm. Primary liver tumors commonly metastasize to the lung.

Clinical Manifestations and Diagnostic Studies

Liver cancer can be difficult to diagnose and differentiate from cirrhosis. They have similar clinical manifestations (e.g., hepatomegaly, splenomegaly, jaundice, weight loss, peripheral edema, ascites, portal hypertension). Other common manifestations of liver cancer include dull abdominal pain in the epigastric or right upper quadrant region, anorexia, nausea and vomiting, and increased abdominal girth. Patients with advanced HCC can have pulmonary emboli and portal vein thrombosis.

Tests used to screen and diagnose liver cancer are ultrasound, CT, and MRI. A percutaneous biopsy is performed when the results of diagnostic imaging studies are inconclusive or tissue is needed to guide treatment. Risks of biopsy include bleeding and potential tumor cell spread. Serum α-fetoprotein (AFP) levels are elevated in approximately 60% of patients with HCC. The level of elevation may not correlate with the clinical features of HCC (e.g., stage or prognosis). (AFP is discussed in Chapter 16.)

NURSING AND COLLABORATIVE MANAGEMENT LIVER CANCER

Prevention of liver cancer focuses on identifying and treating chronic hepatitis B and C viral infections. Treatment of chronic alcohol ingestion may also lower the risk of liver cancer. Screening for at-risk patients usually involves a combination of serum AFP and either CT, MRI, or ultrasound imaging of the liver, usually obtained every 6 to 12 months.

Treatment of liver cancer depends on the size and number of tumors, any spreading beyond the liver, and the patient's age and overall health. In general, the management is similar to that for cirrhosis. Surgical excision (partial hepatectomy) is performed when there is no evidence of invasion of hepatic blood vessels. Surgical resection is possible in only about 15% of patients because the cancer is usually too advanced when the patient is diagnosed. However, surgical interventions offer the best chance for cure of HCC. Liver transplantation is performed when the tumor is localized. Other treatment options are radiofrequency ablation, chemoembolization, and alcohol injection.

In *radiofrequency ablation* (RFA), a thin needle is inserted into the core of the tumor. Then electrical energy is used to create heat in a specific location for a limited time. The end result is destruction of tumor cells. This procedure can be done percutaneously, laparoscopically, or through an open incision. RFA can be used to treat tumors that are less than 5 cm in size and for palliative purposes. Complications are not common but can include infection, bleeding, dysrhythmias, and skin burn.

Chemoembolization (sometimes called transarterial chemoembolization [TACE]) is a minimally invasive procedure frequently performed in the interventional radiology department. A catheter is placed in the arteries to the tumor and an embolic agent is administered, mixed with one or more chemotherapy agents. The embolic agent reduces the blood supply, thus allowing greater exposure of liver cells to the chemotherapy drugs.

With the technique of alcohol injection, surgeons or interventional radiologists identify (with the use of ultrasound) the location of the liver tumor(s). They insert a needle into the tumor and inject a liquid containing a high concentration of alcohol. The concentrated alcohol kills cells, mostly liver cancer cells. This form of treatment is most effective in treating small liver tumors (less than 3 cm).

Systemic chemotherapy is not used for patients with HCC because of the poor response rates. Sorafenib (Nexavar), a targeted therapy, is used to treat metastatic liver cancer. It inhibits new blood vessel growth to tumors (see Table 16-13).

Nursing intervention for the patient with liver cancer focuses on keeping the patient as comfortable as possible. Because this patient manifests the same problems as any patient with advanced liver disease, the nursing interventions discussed for cirrhosis of the liver apply. (See Chapter 16 for care of the patient with cancer.)

The prognosis for patients with liver cancer is poor. The cancer grows rapidly, and death may occur within 6 to 12 months as a result of hepatic encephalopathy or massive blood loss from GI bleeding.

LIVER TRANSPLANTATION

Liver transplantation has become a practical therapeutic option for many people with end-stage liver disease or localized HCC. Liver disease related to chronic viral hepatitis is the leading indication for liver transplantation. Other indications include congenital biliary abnormalities (biliary atresia), inborn errors of metabolism, liver cancer, sclerosing cholangitis, acute liver failure, and chronic end-stage liver disease. Liver transplants are not recommended for the patient with widespread malignant disease. Currently about 17,000 people are waiting for liver transplants. However, only 6000 transplants are performed annually.[31]

Liver transplant candidates must go through a rigorous presurgery screening. This is done to confirm the diagnosis of end-stage liver disease and to assess for other co-morbid conditions (e.g., cardiovascular disease, chronic kidney disease) that may affect the patient's surgical outcome. The evaluation includes physical examination, laboratory tests (CBC, liver function tests), cardiac and pulmonary evaluations, endoscopy, CT scan, and psychologic testing. Potential recipients receive counseling regarding cigarette smoking and alcohol abstinence. Contraindications for liver transplant include severe extrahepatic disease, advanced hepatocellular carcinoma or other cancer, ongoing drug or alcohol abuse, and inability to comprehend or comply with the rigorous posttransplant course.

Liver transplantation is performed using both deceased (cadaver) and live donor livers. (See Chapter 14 for a general discussion of organ transplants.) The live donor liver transplant was developed initially for children whose parents wanted to serve as donors. Today, some liver transplant centers are performing live liver transplant procedures for adults. In this procedure, the living person donates a portion of his or her liver to another. However, live liver donation poses potential risks to the donor, including biliary problems, hepatic artery thrombosis, wound infection, postoperative ileus, and pneumothorax.

Because of the scarcity of available livers, a donor liver may be divided into two parts (split liver transplant) and implanted into two recipients. The decision to use a split donor liver is based on the donor's size and health. The recipients of the split liver generally are smaller than the donor. The success rate associated with split liver transplantation is somewhat lower than that associated with whole organ transplantation because of complications.

Postoperative complications of liver transplant include bleeding, infection, and rejection. However, the liver is subject to a less aggressive immunologic attack than other organs such as the kidneys. (Transplants and immunosuppressive therapy are discussed in Chapter 14.)

Immunosuppressive therapy generally involves a combination of corticosteroids (prednisone), a calcineurin inhibitor (cyclosporine or tacrolimus), and an antiproliferative agent (e.g., azathioprine). (Immunosuppressive therapy is presented in Table 14-16.) Tacrolimus appears to be superior to cyclosporine in liver transplantation and is being used in many centers. Standard regimens often change during the course of a liver transplant recipient's life. In addition, corticosteroid withdrawal, which has been shown to be relatively safe in liver transplant recipients, has been done in some centers.

Approximately 78% of patients survive more than 5 years after liver transplant. Long-term survival depends on the cause of liver failure (e.g., localized liver cancer, chronic hepatitis B or C, biliary disease). Patients who have liver disease secondary to viral hepatitis often experience reinfection of the transplanted liver with hepatitis B or C. For patients with HBV, treatment after surgery with IV HBIG and one of the nucleoside or nucleotide analogs (used to treat HBV infection) has reduced the rates of reinfection of the transplanted liver.

Patients with HCV have lower survival rates than other patient groups. Factors that may contribute to recurrent HCV include the donor's advanced age, HCV genotype 1, high HCV RNA levels before the transplant, and co-infection with other viruses (e.g., cytomegalovirus). Although the recurrence of HCV is nearly universal after liver transplantation, avoidance of changes in immunosuppressive regimen helps to prevent clinically aggressive disease. Because of adverse effects associated with its use, antiviral therapy for hepatitis C after transplant is initiated on an individual basis.

The patient who has had a liver transplant requires highly skilled nursing care, either in an ICU or in some other specialized unit. Postoperative nursing care includes assessing neurologic status; monitoring for signs of hemorrhage; preventing pulmonary complications; monitoring drainage, electrolyte levels, and urine output; and monitoring for signs and symptoms of infection and rejection. Common respiratory problems are pneumonia, atelectasis, and pleural effusions. To prevent these complications, encourage the patient to use measures such as coughing, deep breathing, incentive spirometry, and repositioning. Measure the drainage from the Jackson-Pratt drain, NG tube, and T tube, and note the color and consistency of the drainage.

The first 2 months after the surgery are critical for monitoring for infection. Infection can be viral, fungal, or bacterial. Fever may be the only sign of infection. Emotional support and teaching for the patient and caregiver are essential.

GERONTOLOGIC CONSIDERATIONS

LIVER DISEASE IN THE OLDER ADULT

The incidence of liver disease increases with age. With aging, the liver's size and metabolism of drugs decrease, and hepatobiliary function is altered. The liver has a decreased ability to respond to injury, particularly to regenerate after injury.[32] Transplanted livers take longer to regenerate in the older adult compared with the younger adult.

Older adults are particularly vulnerable to drug-induced liver injury. This is due to several factors, including increased use of prescription and OTC drugs, which can lead to drug interactions and potential drug toxicity. Age-related decreases in liver function caused by decreased liver blood flow and enzyme activity result in decreased drug metabolism. In addition, with aging the liver is less able to recover from drug-induced injury.

A growing number of older adults have chronic hepatitis C and subsequent cirrhosis. HCV and elevated liver enzymes may be found during a routine health assessment. Because older adults have more co-morbid conditions, liver transplant following liver failure may not be an option.

Lifetime health behaviors may also influence the development of chronic liver disease in the older adult. Chronic alcohol abuse and obesity can contribute to cirrhosis, fatty liver inflammation (NASH), and subsequent liver failure. Because of co-morbid cardiovascular and pulmonary diseases, the older adult is less able to tolerate variceal bleeding. In the older adult

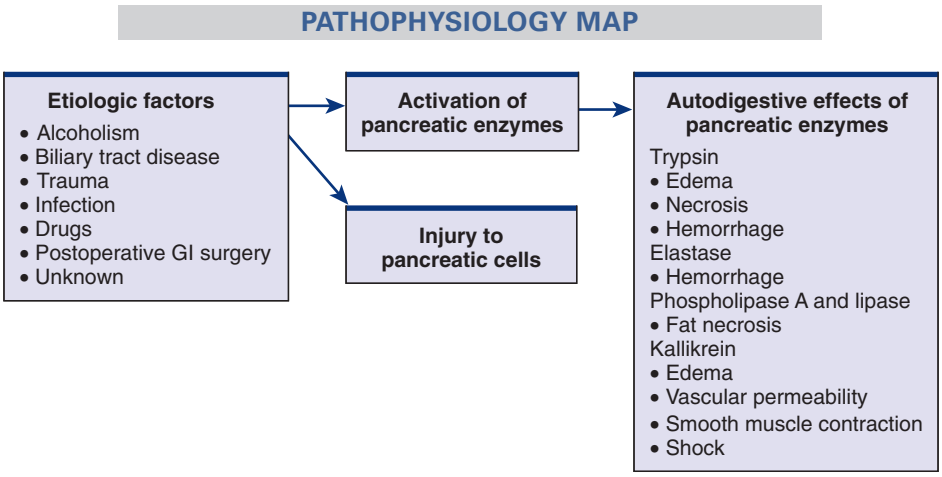

FIG. 44-11 Pathogenic process of acute pancreatitis.

with liver disease, hepatic encephalopathy may be misdiagnosed as dementia.

DISORDERS OF THE PANCREAS

ACUTE PANCREATITIS

Acute pancreatitis is an acute inflammation of the pancreas. The degree of inflammation varies from mild edema to severe hemorrhagic necrosis. Acute pancreatitis is most common in middle-aged men and women. On an annual basis, approximately 210,000 persons are admitted to the hospital with acute pancreatitis. It affects women and men equally. The rate of pancreatitis in African Americans is three times higher than in whites.

Etiology and Pathophysiology

Many factors can cause injury to the pancreas. In the United States the most common cause is gallbladder disease (gallstones), which is more common in women. The second most common cause is chronic alcohol intake, which is more common in men.

Smoking is an independent risk factor for acute pancreatitis. **Biliary sludge** or microlithiasis, which is a mixture of cholesterol crystals and calcium salts, is found in 20% to 40% of patients with acute pancreatitis. The formation of biliary sludge is seen in patients with bile stasis. Acute pancreatitis attacks are also associated with hypertriglyceridemia (serum levels over 1000 mg/dL). Other less common causes of acute pancreatitis include trauma (postsurgical, abdominal), viral infections (mumps, coxsackievirus B, HIV), penetrating duodenal ulcer, cysts, abscesses, cystic fibrosis, Kaposi sarcoma, certain drugs (corticosteroids, thiazide diuretics, oral contraceptives, sulfonamides, NSAIDs), metabolic disorders (hyperparathyroidism, renal failure), and vascular diseases.[33]

Pancreatitis may occur after surgical procedures on the pancreas, stomach, duodenum, or biliary tract. Pancreatitis can also develop following endoscopic retrograde cholangiopancreatography (ERCP). In some cases the cause is unknown (idiopathic).

The most common pathogenic mechanism is autodigestion of the pancreas (Fig. 44-11). The etiologic factors injure pancreatic cells or activate the pancreatic enzymes in the pancreas rather than in the intestine. This may be due to reflux of bile

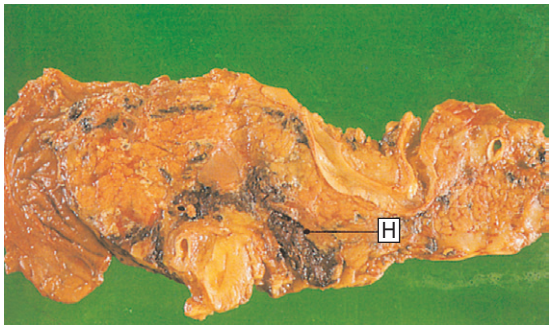

FIG. 44-12 In acute pancreatitis, the pancreas appears edematous and is commonly hemorrhagic *(H)*.

acids into the pancreatic ducts through an open or distended sphincter of Oddi. This reflux may be caused by blockage created by gallstones. Obstruction of pancreatic ducts results in pancreatic ischemia.

Trypsinogen is an inactive proteolytic enzyme produced by the pancreas. It is released into the small intestine via the pancreatic duct. In the intestine it is activated to trypsin by enterokinase. Normally, trypsin inhibitors in the pancreas and plasma bind and inactivate any trypsin that is inadvertently produced. In pancreatitis, activated trypsin in the pancreas can digest the pancreas and produce bleeding.

The exact mechanism by which chronic alcohol intake predisposes a person to pancreatitis is not known. It is thought that alcohol increases the production of the digestive enzymes in the pancreas. Approximately 5% to 10% of alcohol abusers develop pancreatitis. This suggests that environmental (high-fat diet, smoking) and genetic factors may also contribute.

The pathophysiologic involvement of acute pancreatitis is classified as either *mild pancreatitis* (also known as edematous or interstitial pancreatitis) or *severe pancreatitis* (also called *necrotizing pancreatitis*) (Fig. 44-12). In severe pancreatitis, approximately half the patients have permanent decreases in endocrine and exocrine function. Patients with severe pancreatitis are also at high risk of developing pancreatic necrosis, organ failure, and septic complications, resulting in a 25% mortality rate.[33,34]

Clinical Manifestations

Abdominal pain is the predominant manifestation of acute pancreatitis. The pain is due to distention of the pancreas, perito-

neal irritation, and obstruction of the biliary tract. The pain is usually located in the left upper quadrant, but it may be in the midepigastrium. It commonly radiates to the back because of the retroperitoneal location of the pancreas. The pain has a sudden onset and is described as severe, deep, piercing, and continuous or steady. The pain is aggravated by eating and frequently has its onset when the patient is recumbent. It is not relieved by vomiting. The pain may be accompanied by flushing, cyanosis, and dyspnea. The patient may assume various positions involving flexion of the spine in an attempt to relieve the severe pain. Other manifestations of acute pancreatitis include nausea and vomiting, low-grade fever, leukocytosis, hypotension, tachycardia, and jaundice.

Abdominal tenderness with muscle guarding is common. Bowel sounds may be decreased or absent. Paralytic ileus may occur and causes marked abdominal distention. The lungs are frequently involved, with crackles present. Intravascular damage from circulating trypsin may cause areas of cyanosis or greenish to yellow-brown discoloration of the abdominal wall. Other areas of ecchymoses are the flanks (*Grey Turner's spots* or *sign,* a bluish flank discoloration) and the periumbilical area (*Cullen's sign,* a bluish periumbilical discoloration). These result from seepage of blood-stained exudate from the pancreas and may occur in severe cases.

Shock may occur because of hemorrhage into the pancreas, toxemia from the activated pancreatic enzymes, or hypovolemia as a result of fluid shift into the retroperitoneal space (massive fluid shifts).

Complications

The severity of the disease varies according to the extent of pancreatic destruction. Some patients recover completely, others have recurring attacks, and others develop chronic pancreatitis. Acute pancreatitis can be life threatening.

Two significant local complications of acute pancreatitis are pseudocyst and abscess. A pancreatic pseudocyst is an accumulation of fluid, pancreatic enzymes, tissue debris, and inflammatory exudates surrounded by a wall. Manifestations of pseudocyst are abdominal pain, palpable epigastric mass, nausea, vomiting, and anorexia. The serum amylase level frequently remains elevated. CT, MRI, and endoscopic ultrasound (EUS) may be used in the detection of a pseudocyst. The cysts usually resolve spontaneously within a few weeks but may perforate, causing peritonitis, or rupture into the stomach or the duodenum. Treatment options include surgical drainage, percutaneous catheter placement and drainage, and endoscopic drainage.

A *pancreatic abscess* is a collection of pus. It results from extensive necrosis in the pancreas. It may become infected or perforate into adjacent organs. Manifestations of an abscess include upper abdominal pain, abdominal mass, high fever, and leukocytosis. Pancreatic abscesses require prompt surgical drainage to prevent sepsis.

The main systemic complications of acute pancreatitis are pulmonary (pleural effusion, atelectasis, pneumonia, and acute respiratory distress syndrome [ARDS]) and cardiovascular (hypotension) complications and tetany caused by hypocalcemia. The pulmonary complications are likely due to the passage of exudate containing pancreatic enzymes from the peritoneal cavity through transdiaphragmatic lymph channels. Enzyme-induced inflammation of the diaphragm occurs with the end result being atelectasis caused by reduced diaphragm movement. Trypsin can activate prothrombin and plasminogen, increasing the patient's risk for intravascular thrombi, pulmonary emboli, and disseminated intravascular coagulation. When hypocalcemia occurs, it is a sign of severe disease. It is due in part to the combining of calcium and fatty acids during fat necrosis. The exact mechanisms of how or why hypocalcemia occurs are not well understood.

Patients with severe acute pancreatitis are at risk for abdominal compartment syndrome as a result of intraabdominal hypertension and edema. Abdominal compartment syndrome is discussed in Chapter 43.

TABLE 44-16 DIAGNOSTIC STUDIES

Acute Pancreatitis

Laboratory Test	Abnormal Finding
Serum amylase	↑
Serum lipase	↑
Urinary amylase	↑
Blood glucose	↑
Serum calcium	↓
Serum triglycerides	↑

Diagnostic Studies

The primary diagnostic tests for acute pancreatitis are serum amylase and lipase (Table 44-16). The serum amylase level is usually elevated early and remains elevated for 24 to 72 hours. Serum lipase level, which is also elevated in acute pancreatitis, is an important test because other disorders (e.g., mumps, cerebral trauma, renal transplantation) may increase serum amylase levels. Other findings include an increase in liver enzymes, triglycerides, glucose, and bilirubin and a decrease in calcium.

Diagnostic evaluation of acute pancreatitis is also directed at determining the cause. An abdominal ultrasound, x-ray, or contrast-enhanced CT scan can be used to identify pancreatic problems. CT scan is the best imaging test for pancreatitis and related complications such as pseudocysts and abscesses. ERCP is used (although ERCP can cause acute pancreatitis), along with EUS, magnetic resonance cholangiopancreatography (MRCP), and angiography. Chest x-rays may show pulmonary changes, including atelectasis and pleural effusions.

Collaborative Care

Goals of collaborative care for acute pancreatitis include (1) relief of pain; (2) prevention or alleviation of shock; (3) reduction of pancreatic secretions; (4) correction of fluid and electrolyte imbalances; (5) prevention or treatment of infections; and (6) removal of the precipitating cause, if possible (Table 44-17).

Conservative Therapy. Treatment is primarily focused on supportive care, including aggressive hydration, pain management, management of metabolic complications, and minimization of pancreatic stimulation. Treatment and control of pain are very important. IV morphine may be used. Pain medications may be combined with an antispasmodic agent. However, atropine and other anticholinergic drugs should be avoided when paralytic ileus is present because they can decrease GI mobility, thus contributing to the problem. Other medications that relax smooth muscles (spasmolytics), such as nitroglycerin or papaverine, may be used. Supplemental oxygen is provided to maintain oxygen saturation greater than 95%. In patients with severe pancreatitis, serum glucose levels are closely monitored for hyperglycemia.

TABLE 44-17 COLLABORATIVE CARE

Acute Pancreatitis

Diagnostic

- History and physical examination
- Serum amylase
- Serum lipase
- Blood glucose
- Serum calcium
- Serum triglycerides
- Flat plate of the abdomen
- Abdominal ultrasound
- Endoscopic ultrasound (EUS)
- Contrast-enhanced CT of pancreas
- Magnetic resonance cholangiopancreatography (MRCP)
- Endoscopic retrograde cholangiopancreatography (ERCP)
- Chest x-ray

Collaborative Therapy

- Pain medication (e.g., morphine)
- NPO with NG tube to suction
- Albumin (if shock present)
- IV calcium gluconate (10%) (if tetany present)
- Lactated Ringer's solution
- Proton pump inhibitor (e.g., omeprazole [Prilosec])
- Antibiotics (if necrotizing pancreatitis)

TABLE 44-18 DRUG THERAPY

Acute and Chronic Pancreatitis

Drug	Mechanism of Action
Acute Pancreatitis	
morphine	Relief of pain
Antispasmodics (e.g., dicyclomine [Bentyl])	↓ Vagal stimulation, motility, pancreatic outflow (↓ volume and concentration of bicarbonate and enzyme secretion) Contraindicated in paralytic ileus
Carbonic anhydrase inhibitor (acetazolamide [Diamox])	↓ Volume and bicarbonate concentration of pancreatic secretion
Antacids	Neutralization of gastric hydrochloric (HCl) acid secretion ↓ Production and secretion of pancreatic enzymes and bicarbonate
Proton pump inhibitors (omeprazole [Prilosec])	↓ HCl acid secretion (HCl acid stimulates pancreatic activity)
Chronic Pancreatitis	
Pancreatic enzyme products (pancrelipase [Pancrease, Zenpep, Creon, Viokase])	Replacement therapy for pancreatic enzymes
Insulin	Treatment for diabetes mellitus or hyperglycemia, if needed

If shock is present, blood volume replacements are used. Plasma or plasma volume expanders such as dextran or albumin may be given. Fluid and electrolyte imbalances are corrected with lactated Ringer's solution or other electrolyte solutions. Central venous pressure readings may be used to assist in determining fluid replacement requirements. Vasoactive drugs such as dopamine (Intropin) may be used to increase systemic vascular resistance in patients with ongoing hypotension.

It is important to reduce or suppress pancreatic enzymes to decrease stimulation of the pancreas and allow it to rest. This is accomplished in several ways. First, the patient is NPO (taking nothing by mouth). Second, NG suction may be used to reduce vomiting and gastric distention and to prevent gastric acidic contents from entering the duodenum. In addition, certain drugs may be used to suppress gastric acid secretion (Table 44-18). With resolution of the pancreatitis, the patient resumes oral intake. For the patient with severe acute pancreatitis who does not resume oral intake, enteral nutrition support may be initiated.

The inflamed and necrotic pancreatic tissue is a good medium for bacterial growth. In patients with acute necrotizing pancreatitis, infection is the leading cause of morbidity and mortality. Therefore it is important to prevent infections. Because many of the organisms come from the intestine, enteral feeding reduces the risk of necrotizing pancreatitis. Monitor the patient closely so that antibiotic therapy can be instituted early if necrosis and infection occur. Endoscopic- or CT-guided percutaneous aspiration with Gram stain and culture may be performed.

Surgical Therapy. When the acute pancreatitis is related to gallstones, an urgent ERCP plus endoscopic *sphincterotomy* (severing of the muscle layers of the sphincter of Oddi) may be done. This may be followed by laparoscopic cholecystectomy to reduce the potential for recurrence. Surgical intervention may also be indicated when the diagnosis is uncertain and for patients who do not respond to conservative therapy. Those with severe acute pancreatitis may require drainage of necrotic fluid collections. This is done either surgically, under CT guidance, or endoscopically. Percutaneous drainage of a pseudocyst can be performed, and a drainage tube is left in place.

Drug Therapy. Several different drugs are used to prevent and treat problems associated with pancreatitis (see Table 44-18). Currently there are no drugs that cure pancreatitis.

Nutritional Therapy. Initially the patient with acute pancreatitis is on NPO status to reduce pancreatic secretion. Depending on the severity of the pancreatitis, enteral feedings via nasojejunal tube are initiated. Because of infection risk, parenteral nutrition is reserved for patients who cannot tolerate enteral nutrition (see Chapter 40). If IV lipids are ordered, blood triglyceride levels need to be monitored. In cases of moderate to severe pancreatitis, the patient may require enteral feeding via a jejunal feeding tube. When food is allowed, small, frequent feedings are given. The diet is usually high in carbohydrate content because that is the least stimulating to the exocrine portion of the pancreas. Suspect intolerance to oral foods when the patient reports pain, has increasing abdominal girth, or has elevations in serum amylase and lipase levels. The patient needs to abstain from alcohol. Supplemental fat-soluble vitamins may be given.

NURSING MANAGEMENT ACUTE PANCREATITIS

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a person with acute pancreatitis are presented in Table 44-19.

NURSING DIAGNOSES

Nursing diagnoses for the patient with acute pancreatitis may include, but are not limited to, the following:

- Acute pain *related to* distention of pancreas, peritoneal irritation, obstruction of biliary tract, and ineffective pain and comfort measures
- Deficient fluid volume *related to* nausea, vomiting, restricted oral intake, and fluid shift into the retroperitoneal space

TABLE 44-19 NURSING ASSESSMENT

Acute Pancreatitis

Subjective Data

Important Health Information

Past health history: Biliary tract disease, alcohol use, abdominal trauma, duodenal ulcers, infection, metabolic disorders

Medications: Thiazides, nonsteroidal antiinflammatory drugs

Surgery or other treatments: Surgical procedures on the pancreas, stomach, duodenum, or biliary tract; endoscopic retrograde cholangiopancreatography (ERCP)

Functional Health Patterns

Health perception–health management: Alcohol abuse; fatigue

Nutritional-metabolic: Nausea and vomiting; anorexia

Activity-exercise: Dyspnea

Cognitive-perceptual: Severe midepigastric or left upper quadrant pain that may radiate to the back, aggravated by food and alcohol intake and unrelieved by vomiting

Objective Data

General

Restlessness, anxiety, low-grade fever

Integumentary

Flushing, diaphoresis, discoloration of abdomen and flanks, cyanosis, jaundice; decreased skin turgor, dry mucous membranes

Respiratory

Tachypnea, basilar crackles

Cardiovascular

Tachycardia, hypotension

Gastrointestinal

Abdominal distention, tenderness, and muscle guarding; diminished bowel sounds

Possible Diagnostic Findings

↑ Serum amylase and lipase, leukocytosis, hyperglycemia, hypocalcemia, abnormal ultrasound and CT scans of pancreas, abnormal ERCP or MRCP

- Imbalanced nutrition: less than body requirements *related to* anorexia, dietary restrictions, nausea, loss of nutrients from vomiting, and impaired digestion
- Ineffective self-health management *related to* lack of knowledge of preventive measures, diet restrictions, alcohol restriction intake, and follow-up care

Additional information on nursing diagnoses for the patient with acute pancreatitis is presented in eNursing Care Plan 44-3 (available on the website for this chapter).

PLANNING

The overall goals are that the patient with acute pancreatitis will have (1) relief of pain, (2) normal fluid and electrolyte balance, (3) minimal to no complications, and (4) no recurrent attacks.

NURSING IMPLEMENTATION

HEALTH PROMOTION. The major factors involved in health promotion are (1) assessment of the patient for predisposing and etiologic factors and (2) encouragement of early treatment of these factors to prevent acute pancreatitis. Encourage early diagnosis and treatment of biliary tract disease, such as cholelithiasis. Encourage the patient to eliminate alcohol intake, especially if he or she has had any previous episodes of pancreatitis. Attacks of pancreatitis become milder or disappear with the discontinuance of alcohol use.

ACUTE INTERVENTION. During the acute phase, it is important to monitor vital signs. Hemodynamic stability may be compromised by hypotension, fever, and tachypnea. Monitor the response to IV fluids. Also closely monitor fluid and electrolyte balance. Frequent vomiting, along with gastric suction, may result in decreased chloride, sodium, and potassium levels.

Respiratory failure may develop in the patient with severe acute pancreatitis. Assess respiratory function (e.g., lung sounds, oxygen saturation levels). If ARDS develops, the patient may require intubation and mechanical ventilatory support.

SAFETY ALERT

- Assess for respiratory distress in the patient with severe acute pancreatitis.
- Listen to lung sounds and monitor O_2 saturation on a regular basis.

Because hypocalcemia can also occur, observe for symptoms of tetany, such as jerking, irritability, and muscular twitching. Numbness or tingling around the lips and in the fingers is an early indicator of hypocalcemia. Assess the patient for a positive Chvostek's sign or Trousseau's sign (see Fig. 17-15). Calcium gluconate (as ordered) should be given to treat symptomatic hypocalcemia. Hypomagnesemia may also develop, necessitating the monitoring of serum magnesium levels.

Because abdominal pain is a prominent symptom of pancreatitis, a major focus of your care is the relief of pain (see eNursing Care Plan 44-3). Pain and restlessness can increase the metabolic rate and subsequent stimulation of pancreatic enzymes. In addition, acute pain can contribute to hemodynamic instability. Morphine may be used for pain relief. Assess and document the duration of pain relief. Measures such as comfortable positioning, frequent changes in position, and relief of nausea and vomiting assist in reducing the restlessness that usually accompanies the pain. Assuming positions that flex the trunk and draw the knees up to the abdomen may decrease pain. A side-lying position with the head elevated 45 degrees decreases tension on the abdomen and may help ease the pain.

For the patient who is on NPO status or has an NG tube, provide frequent oral and nasal care to relieve the dryness of the mouth and nose. Oral care is essential to prevent parotitis. If the patient is taking anticholinergics to decrease GI secretions, the mouth will be especially dry. If the patient is taking antacids to neutralize gastric acid secretion, they should be sipped slowly or inserted in the NG tube.

Observe for fever and other manifestations of infection in the patient with acute pancreatitis. Respiratory tract infections are common because the retroperitoneal fluid raises the diaphragm, which causes the patient to take shallow, guarded abdominal breaths. Measures to prevent respiratory tract infections include turning, coughing, deep breathing, and assuming a semi-Fowler's position.

Other important assessments are observation for signs of paralytic ileus, renal failure, and mental changes. Determine the blood glucose level to assess damage to the β cells of the islets of Langerhans in the pancreas.

After pancreatic surgery, the patient may require special wound care for an anastomotic leak or a fistula. To prevent skin irritation, use skin barriers (e.g., Stomahesive, Karaya Paste, or Colly-Seel), pouching, and drains. In addition to protecting the skin, pouching also permits a more accurate determination of fluid and electrolyte losses and increases patient comfort.

Sterile pouching systems are available. Consult with a clinical specialist or wound, ostomy, and continence (WOC) nurse, if available.

AMBULATORY AND HOME CARE. After acute pancreatitis, the patient may require home care follow-up. Because of loss of physical and muscle strength, physical therapy may be needed. Continued care to prevent infection and detect any complications is important. Counseling regarding abstinence from alcohol is important to prevent the patient from experiencing future attacks of acute pancreatitis and development of chronic pancreatitis. Because cigarettes can stimulate the pancreas, smoking should be avoided.

Dietary teaching should include restriction of fats because they stimulate the secretion of cholecystokinin, which then stimulates the pancreas. Carbohydrates are less stimulating to the pancreas and are encouraged. Instruct the patient to avoid crash dieting and bingeing because they can precipitate attacks.

Instruct the patient and the caregiver to recognize and report symptoms of infection, diabetes mellitus, or steatorrhea (foul-smelling, frothy stools). These changes indicate possible ongoing destruction of pancreatic tissue. Teach the patient and caregiver about the prescribed regimen, including the importance of taking the required medications and following the recommended diet.

EVALUATION

The expected outcomes are that the patient with acute pancreatitis will

- Have adequate pain control
- Maintain adequate fluid balance
- Be knowledgeable about treatment regimen to restore health
- Get help for alcohol dependence (if appropriate)

CHRONIC PANCREATITIS

Chronic pancreatitis is a continuous, prolonged, inflammatory, and fibrosing process of the pancreas. The pancreas is progressively destroyed as it is replaced by fibrotic tissue. Strictures and calcifications may also occur in the pancreas.

Etiology and Pathophysiology

Chronic pancreatitis can be due to alcohol abuse; obstruction caused by cholelithiasis (gallstones), tumor, pseudocysts, or trauma; and systemic diseases (e.g., systemic lupus erythematosus), autoimmune pancreatitis, and cystic fibrosis. Some patients may not have an identifiable risk factor (idiopathic pancreatitis). Chronic pancreatitis may follow acute pancreatitis, but it may also occur in the absence of any history of an acute condition.

The most common cause of obstructive pancreatitis is inflammation of the sphincter of Oddi associated with cholelithiasis. Cancer of the ampulla of Vater, duodenum, or pancreas can also cause this type of chronic pancreatitis.

In nonobstructive pancreatitis there is inflammation and sclerosis, mainly in the head of the pancreas and around the pancreatic duct. This type of chronic pancreatitis is the most common form. In the United States, chronic pancreatitis is found almost exclusively in individuals who abuse alcohol. A genetic factor may predispose a person who drinks to the direct toxic effect of the alcohol on the pancreas.

Clinical Manifestations

As with acute pancreatitis, a major manifestation of chronic pancreatitis is abdominal pain. The patient may have episodes of acute pain, but it usually is chronic (recurrent attacks at intervals of months or years). The attacks may become more and more frequent until they are almost constant, or they may diminish as pancreatic fibrosis develops. The pain is located in the same areas as in acute pancreatitis, but is usually described as a heavy, gnawing feeling or sometimes as burning and cramplike. The pain is not relieved with food or antacids.

Other clinical manifestations include symptoms of pancreatic insufficiency, including malabsorption with weight loss, constipation, mild jaundice with dark urine, steatorrhea, and diabetes mellitus. The steatorrhea may become severe, with voluminous, foul-smelling, fatty stools. Urine and stool may be frothy. Some abdominal tenderness may be present.

Chronic pancreatitis is also associated with a variety of complications, including pseudocyst formation, bile duct or duodenal obstruction, pancreatic ascites or pleural effusion, splenic vein thrombosis, pseudoaneurysms, and pancreatic cancer.

Diagnostic Studies

Confirming the diagnosis of chronic pancreatitis can be challenging. The diagnosis is based on the patient's signs and symptoms, laboratory studies, and imaging. In chronic pancreatitis the levels of serum amylase and lipase may be elevated slightly or not at all, depending on the degree of pancreatic fibrosis. Serum bilirubin and alkaline phosphatase levels may be increased. There is usually mild leukocytosis and an elevated sedimentation rate.

ERCP is used to visualize the pancreatic and common bile ducts. Imaging studies such as CT, MRI, MRCP, abdominal ultrasound, and EUS are useful in patients with chronic pancreatitis. These procedures show a variety of changes, including calcifications, ductal dilation, pseudocysts, and pancreatic enlargement.

Stool samples are examined for fecal fat content. Deficiencies of fat-soluble vitamins and cobalamin, glucose intolerance, and possibly diabetes may also be found in those with chronic pancreatitis. A secretin stimulation test may be used to assess the degree of pancreatic function (see Chapter 39).

Collaborative Care

When the patient with chronic pancreatitis experiences an acute attack, the therapy is identical to that for acute pancreatitis. At other times the focus is on prevention of further attacks, relief of pain, and control of pancreatic exocrine and endocrine insufficiency. It sometimes takes frequent doses of analgesics (morphine or fentanyl patch [Duragesic]) to relieve the pain if dietary measures and enzyme replacement are not effective.

Diet, pancreatic enzyme replacement, and control of diabetes are ways to control the pancreatic insufficiency. Small, bland, frequent meals that are low in fat content are recommended to decrease pancreatic stimulation. Smoking is associated with accelerated progression of chronic pancreatitis. Teach the patient not to consume alcohol and caffeinated beverages.

Pancreatic enzyme products (PEPs) such as pancrelipase (Pancrease, Zenpep, Creon, Viokase) contain amylase, lipase, and trypsin and are used to replace the deficient pancreatic enzymes. They are usually enteric coated to prevent their breakdown or inactivation by gastric acid. Bile salts are sometimes given to facilitate the absorption of the fat-soluble vitamins (A,

D, E, and K) and prevent further fat loss. If diabetes develops, it is controlled with insulin or oral hypoglycemic agents. Acid-neutralizing drugs (e.g., antacids) and acid-inhibiting drugs (e.g., H_2-receptor blockers, proton pump inhibitors) may be given to decrease hydrochloric acid (HCl) secretion but have little overall effect on patient outcomes. Antidepressants, such as nortriptyline (Aventyl), have been shown to reduce the neuropathic pain associated with chronic pancreatitis.

Treatment of chronic pancreatitis sometimes requires endoscopic therapy or surgery. When biliary disease is present or obstruction or pseudocyst develops, surgery may be indicated. Surgical procedures can divert bile flow or relieve ductal obstruction. A choledochojejunostomy diverts bile around the ampulla of Vater, where there may be spasm or hypertrophy of the sphincter. In this procedure the common bile duct is anastomosed into the jejunum. Another type of surgical diverting procedure is the Roux-en-Y pancreatojejunostomy, in which the pancreatic duct is opened and an anastomosis is made with the jejunum. Pancreatic drainage procedures can relieve ductal obstruction and are often done with ERCP. Some patients may undergo ERCP with sphincterotomy and/or stent placement at the site of obstruction. These patients require follow-up procedures such as ERCP to either exchange or remove the stent.

NURSING MANAGEMENT CHRONIC PANCREATITIS

Except during an acute episode, nursing management focuses on chronic care and health promotion. Instruct the patient to take measures to prevent further attacks. Dietary control, along with consistency of other treatment measures, such as taking pancreatic enzymes, is essential. The enzymes are usually taken with meals or a snack. Observe the patient's stools for steatorrhea to help determine the effectiveness of the enzymes. Instruct the patient and the caregiver to observe the stools.

If diabetes has developed, instruct the patient regarding testing of blood glucose levels and drug therapy (see Chapter 49). Ensure that the patient who is taking antisecretory agents or antacids takes them as ordered to control gastric acidity. Antacids should be taken after meals and at bedtime.

The patient must avoid alcohol and may need assistance with this problem. If the patient is dependent on alcohol, referral to other agencies or resources may be necessary (see Chapter 11).

PANCREATIC CANCER

Annually in the United States an estimated 42,500 people are diagnosed with pancreatic cancer, and 35,300 people die from pancreatic cancer.[34] It is the fourth leading cause of death from cancer in the United States. The risk increases with age, with the peak incidence occurring between 65 and 80 years of age.

Most pancreatic tumors are adenocarcinomas originating from the epithelium of the ductal system. More than half of the tumors occur in the head of the pancreas. As the tumor grows, the common bile duct becomes obstructed, and obstructive jaundice develops. Tumors starting in the body or the tail often remain silent until their growth is advanced. The majority of cancers have metastasized at the time of diagnosis. The signs and symptoms of pancreatic cancer are often similar to those of chronic pancreatitis. The prognosis of a patient with cancer of the pancreas is poor. The majority of patients die within 5 to 12 months of the initial diagnosis, and the 5-year survival rate is less than 5%.

Etiology and Pathophysiology

The cause of pancreatic cancer remains unknown. Risk factors for pancreatic cancer include chronic pancreatitis, diabetes mellitus, age, cigarette smoking, family history of pancreatic cancer, high-fat diet, and exposure to chemicals such as benzidine. African Americans have a higher incidence of pancreatic cancer than whites. The most firmly established environmental risk factor is cigarette smoking. Smokers are two to three times more likely to develop pancreatic cancer than nonsmokers. The risk is related to both the duration and amount of cigarettes smoked.

Clinical Manifestations

Common manifestations of pancreatic cancer include abdominal pain (dull, aching), anorexia, rapid and progressive weight loss, nausea, and jaundice. The most common manifestations of cancer of the head of the pancreas are pain, jaundice, and weight loss. Pruritus may accompany obstructive jaundice. In general, pain is common and is related to the location of malignancy. Extreme, unrelenting pain is related to extension of the cancer into the retroperitoneal tissues and nerve plexuses. The pain is frequently located in the upper abdomen or left hypochondrium and often radiates to the back. It is commonly related to eating, and it also occurs at night. Weight loss is due to poor digestion and absorption caused by lack of digestive enzymes from the pancreas.

Diagnostic Studies

Abdominal ultrasound or EUS, spiral CT scan, ERCP, MRI, and MRCP are the most commonly used diagnostic imaging techniques for pancreatic diseases, including cancer. EUS involves imaging the pancreas with the use of an endoscope positioned in the stomach and the duodenum. EUS also allows for fine-needle aspiration of the tumor. CT scan is often the initial study and provides information on metastasis and vascular involvement. ERCP allows visualization of the pancreatic duct and the biliary system. When ERCP is used, pancreatic secretions and tissue can be collected for analysis of different tumor markers. MRI and MRCP may also be used for diagnosing and staging pancreatic cancer. A positron emission tomography (PET) scan or PET/CT scan may also be obtained but usually does not provide additional clinical information.

Tumor markers are used both for establishing the diagnosis of pancreatic adenocarcinoma and for monitoring the response to treatment. Cancer-associated antigen 19-9 (CA 19-9) is elevated in pancreatic cancer and is the most commonly used tumor marker. CA 19-9 can also be elevated in gallbladder cancer or in benign conditions such as acute and chronic pancreatitis, hepatitis, and biliary obstruction.

Collaborative Care

Surgery provides the most effective treatment of cancer of the pancreas. Only 15% to 20% of patients have resectable tumors. The classic surgery is a *radical pancreaticoduodenectomy,* or *Whipple procedure* (Fig. 44-13). This procedure involves resection of the proximal pancreas (proximal pancreatectomy), adjoining duodenum (duodenectomy), distal portion of the stomach (partial gastrectomy), and distal segment of the common bile duct. An anastomosis of the pancreatic duct, common

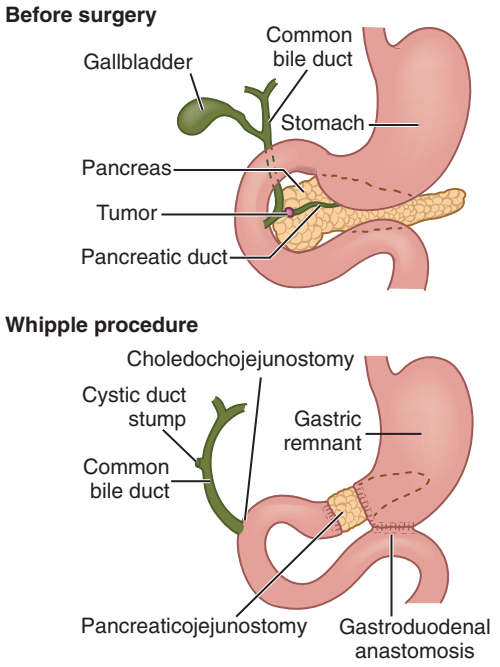

FIG. 44-13 Whipple procedure or radical pancreaticoduodenectomy. This surgical procedure involves resection of the proximal pancreas, adjoining duodenum, distal portion of the stomach, and distal portion of the common bile duct. An anastomosis of the pancreatic duct, common bile duct, and stomach to the jejunum is done.

bile duct, and stomach to the jejunum is done. A total pancreatectomy is performed in some institutions. Sometimes a simple bypass procedure, such as a cholecystojejunostomy to relieve biliary obstruction, may be used as a palliative measure. Some surgeons suggest a more radical resection, such as a total pancreaticoduodenectomy with splenectomy. Endoscopically placed biliary stents can be used as a palliative measure when tumors compress the bile duct.

Radiation therapy alone has little effect on survival, but may be effective for pain relief. External radiation is usually used, but implantation of internal radiation seeds into the tumor has also been used. The current role of chemotherapy in pancreatic cancer is limited. Chemotherapy usually consists of fluorouracil (5-FU) and gemcitabine (Gemzar) either alone or in combination with agents such as capecitabine (Xeloda) or erlotinib (Tarceva). Erlotinib is a targeted therapy (see Table 16-13).

NURSING MANAGEMENT PANCREATIC CANCER

Because the patient with pancreatic cancer has many of the same problems as the patient with pancreatitis, nursing care includes many of the same measures (see sections on acute and chronic pancreatitis). Provide symptomatic and supportive nursing care. This includes administration of medications and comfort measures to relieve pain. Psychologic support is essential, especially during times of anxiety or depression.

Adequate nutrition is an important part of the nursing care plan. Frequent and supplemental feedings may be necessary. Measures to stimulate the appetite as much as possible and to overcome anorexia, nausea, and vomiting should be included in the nursing care. Because bleeding can result from impaired vitamin K production, assess for bleeding from body orifices

FIG. 44-14 Cholesterol gallstones in a gallbladder that was removed.

and mucous membranes. If the patient is undergoing radiation therapy, observe for adverse reactions, such as anorexia, nausea, vomiting, and skin irritation.

The prognosis for a patient with pancreatic cancer is poor. A significant component of the nursing care is helping the patient and caregiver through the grieving process. Chapter 10 provides information on palliative and end-of-life care.

DISORDERS OF THE BILIARY TRACT

CHOLELITHIASIS AND CHOLECYSTITIS

The most common disorder of the biliary system is **cholelithiasis** (stones in the gallbladder) (Fig. 44-14 and eFig. 44-3 on the website for this chapter). The stones may be lodged in the neck of the gallbladder or in the cystic duct. **Cholecystitis** (inflammation of the gallbladder) is usually associated with cholelithiasis. Cholecystitis may be acute or chronic. Cholelithiasis and cholecystitis usually occur together.

Gallbladder disease is a common health problem in the United States. Approximately 8% to 10% of American adults have cholelithiasis. The actual number is not known because many persons with stones are asymptomatic. *Cholecystectomy* (removal of the gallbladder) ranks among the most common surgical procedures performed in the United States.

The incidence of cholelithiasis is higher in women, especially multiparous women, and persons over 40 years of age. Postmenopausal women on estrogen therapy are at somewhat greater risk of having gallbladder disease than are women who are taking birth control pills. Oral contraceptives affect cholesterol production and increase the likelihood of gallbladder cholesterol saturation. Other factors that increase the occurrence of gallbladder disease are a sedentary lifestyle, a familial tendency, and obesity. Obesity causes increased secretion of cholesterol in bile.

Gallbladder disease is more common in Asian Americans and African Americans than in whites. The incidence is especially high in the Native American population, particularly in the Navajo and Pima tribes.

Etiology and Pathophysiology

Cholelithiasis. The cause of gallstones is unknown. Cholelithiasis develops when the balance that keeps cholesterol, bile salts, and calcium in solution is altered so that these substances precipitate. Conditions that upset this balance include infection

GENDER DIFFERENCES

Cholelithiasis

Men	Women
• Incidence of cholelithiasis is lower in men than in women. • Gender differences in incidence decrease after age 50.	• Pregnancy is the greatest risk factor for increased prevalence in women. • Obesity increases the risk, especially for women.

TABLE 44-20 MANIFESTATIONS OF OBSTRUCTED BILE FLOW

Manifestation	Etiology
Obstructive jaundice	No bile flow into duodenum
Dark amber urine, which foams when shaken	Soluble bilirubin in urine
No urobilinogen in urine	No bilirubin reaching small intestine to be converted to urobilinogen
Clay-colored stools	Same as above
Pruritus	Deposition of bile salts in skin tissues
Intolerance for fatty foods (nausea, sensation of fullness, anorexia)	No bile in small intestine for fat digestion
Bleeding tendencies	Lack of or decreased absorption of vitamin K, resulting in decreased production of prothrombin
Steatorrhea	No bile salts in duodenum, preventing fat emulsion and digestion

and disturbances in the metabolism of cholesterol. In patients with cholelithiasis, the bile secreted by the liver is supersaturated with cholesterol (lithogenic bile). The bile in the gallbladder also becomes supersaturated with cholesterol. When bile is supersaturated with cholesterol, precipitation of cholesterol occurs.

Other components of bile that precipitate into stones are bile salts, bilirubin, calcium, and protein. Mixed cholesterol stones, which are predominantly cholesterol, are the most common gallstones.

Changes in the composition of bile are probably significant in the formation of gallstones. Stasis of bile leads to progression of the supersaturation and changes in the chemical composition of the bile (biliary sludge). Immobility, pregnancy, and inflammatory or obstructive lesions of the biliary system decrease bile flow. Hormonal factors during pregnancy may cause delayed emptying of the gallbladder, resulting in stasis of bile.

The stones may remain in the gallbladder or migrate to the cystic duct or the common bile duct. They cause pain as they pass through the ducts, and they may lodge in the ducts and produce an obstruction. Small stones are more likely to move into a duct and cause obstruction. Table 44-20 depicts the changes and manifestations that occur when the stones obstruct the common bile duct. If the blockage occurs in the cystic duct, the bile can continue to flow into the duodenum directly from the liver. However, when the bile in the gallbladder cannot escape, this stasis of bile may lead to cholecystitis.

Cholecystitis. Cholecystitis is most commonly associated with obstruction caused by gallstones or biliary sludge. Cholecystitis in the absence of obstruction *(acalculous cholecystitis)* occurs most frequently in older adults and in patients who are critically ill. Acalculous cholecystitis is also associated with prolonged immobility and fasting, prolonged parenteral nutrition, and diabetes mellitus. Bacteria reaching the gallbladder via the vascular or lymphatic route, or chemical irritants in the bile, can also produce cholecystitis. *E. coli*, streptococci, and salmonellae are common causative bacteria. Other etiologic factors include adhesions, neoplasms, anesthesia, and opioids.

Inflammation is the major pathophysiologic condition and may be confined to the mucous lining or involve the entire wall of the gallbladder. During an acute attack of cholecystitis, the gallbladder is edematous and hyperemic, and it may be distended with bile or pus. The cystic duct is also involved and may become occluded. The wall of the gallbladder becomes scarred after an acute attack. Decreased functioning occurs if large amounts of tissue are fibrosed.

Clinical Manifestations

Cholelithiasis may produce severe symptoms or none at all. Many patients have "silent cholelithiasis." The severity of symptoms depends on whether the stones are stationary or mobile and whether obstruction is present. When a stone is lodged in the ducts or when stones are moving through the ducts, spasms may result. The gallbladder spasms occur in response to the stone. This sometimes produces severe pain, which is termed *biliary colic* even though the pain is rarely colicky. The pain is more often steady. The pain can be excruciating and accompanied by tachycardia, diaphoresis, and prostration. The severe pain may last up to an hour, and when it subsides, there is residual tenderness in the right upper quadrant. The attacks of pain frequently occur 3 to 6 hours after a high-fat meal or when the patient lies down. When total obstruction occurs, symptoms related to bile blockage are manifested (see Table 44-20).

Manifestations of cholecystitis vary from indigestion to moderate to severe pain, fever, and jaundice. Initial symptoms of acute cholecystitis include indigestion and pain and tenderness in the right upper quadrant, which may be referred to the right shoulder and scapula. The pain may be acute and be accompanied by nausea and vomiting, restlessness, and diaphoresis. Manifestations of inflammation include leukocytosis and fever. Physical findings include right upper quadrant tenderness and abdominal rigidity. Manifestations of chronic cholecystitis include a history of fat intolerance, dyspepsia, heartburn, and flatulence.

Complications. Complications of cholelithiasis and cholecystitis include gangrenous cholecystitis, subphrenic abscess, pancreatitis, *cholangitis* (inflammation of biliary ducts), biliary cirrhosis, fistulas, and rupture of the gallbladder, which can produce bile peritonitis. In older patients and those with diabetes, gangrenous cholecystitis and bile peritonitis are the most common complications of cholecystitis. *Choledocholithiasis* (stone in the common bile duct) may occur, producing symptoms of obstruction.

Diagnostic Studies

Ultrasonography is commonly used to diagnose gallstones (see Table 39-12). It is especially useful for patients with jaundice (because it does not depend on liver function) and for patients who are allergic to contrast medium. ERCP allows for visualization of the gallbladder, the cystic duct, the common hepatic duct, and the common bile duct. Bile taken during ERCP is sent for culture to identify possible infecting organisms.

Percutaneous transhepatic cholangiography is the insertion of a needle directly into the gallbladder duct followed by injec-

tion of contrast materials. It is generally done after ultrasonography indicates a bile duct blockage.

Laboratory tests reveal an increased white blood cell (WBC) count as a result of inflammation. Both direct and indirect bilirubin levels are elevated, as is the urinary bilirubin level if an obstructive process is present (see Table 44-3). If the common bile duct is obstructed, no bilirubin will reach the small intestine to be converted to urobilinogen. Serum enzymes, such as alkaline phosphatase, ALT, and AST, may be elevated. Serum amylase is increased if there is pancreatic involvement.

Collaborative Care

Once gallstones become symptomatic, definitive surgical intervention with cholecystectomy is usually indicated. However, in some cases, conservative therapy may be considered.

Conservative Therapy

Cholelithiasis. The treatment of gallstones depends on the stage of disease. Bile acids (cholesterol solvents) such as ursodeoxycholic acid (ursodiol) and chenodeoxycholic acid (chenodiol) are used to dissolve stones. However, the gallstones may recur. Gallstones are not usually treated with drugs because of the high use and success of laparoscopic cholecystectomy.

ERCP with endoscopic sphincterotomy (papillotomy) may be used for stone removal (Fig. 44-15). ERCP allows for visualization of the biliary system, dilation (balloon sphincteroplasty), and placement of stents and sphincterotomy if warranted. Special catheters with wire baskets or inflatable balloon tip may be used for stone removal.[34] The endoscope is passed to the duodenum. With an electrodiathermy knife attached to the endoscope, the stone is commonly left in the duodenum to pass naturally in the stool. When a stent is placed, it is generally removed or changed after a few months.

Extracorporeal shock-wave lithotripsy (ESWL) is an alternative treatment employed when stones cannot be removed by endoscopic approaches. In ESWL a lithotriptor uses high-energy shock waves to disintegrate gallstones once they have been located by ultrasound. It usually takes 1 to 2 hours to disintegrate the stones. After they are broken up, the fragments pass through the common bile duct and into the small intestine. Usually ESWL and oral dissolution therapy are used together.

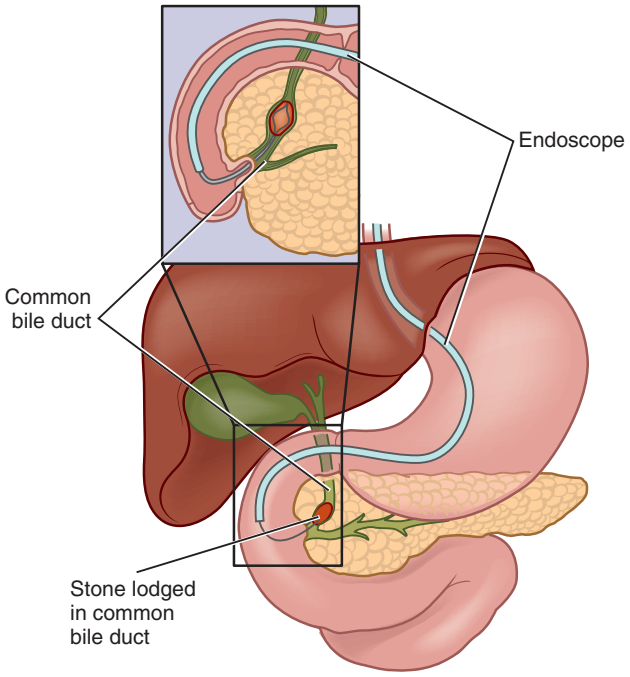

FIG. 44-15 During endoscopic sphincterotomy, an endoscope is advanced through the mouth and stomach until its tip sits in the duodenum opposite the common bile duct. *Inset,* After widening the duct mouth by incising the sphincter muscle, the physician advances a basket attachment into the duct and snags the stone.

Cholecystitis. During an acute episode of cholecystitis, treatment focuses on pain control, control of possible infection with antibiotics, and maintenance of fluid and electrolyte balance (Table 44-21). Treatment is mainly supportive and symptomatic. If nausea and vomiting are severe, NG tube insertion and gastric decompression may be used to prevent further gallbladder stimulation. A cholecystostomy may be used to drain purulent material from the obstructed gallbladder. NSAIDs (e.g., ketorolac [Toradol]) are given for pain management. Anticholinergics may be administered to decrease secretion and counteract smooth muscle spasms.

Surgical Therapy. Laparoscopic cholecystectomy is the treatment of choice for symptomatic cholelithiasis. Approximately 90% of cholecystectomies are done laparoscopically. In this procedure, the gallbladder is removed through one to four small punctures in the abdomen. A laparoscope, which has a camera attached, and grasping forceps are inserted into the abdomen through the punctures. (The incision sites may vary.) Using closed-circuit monitors to view the abdominal cavity, the surgeon retracts and dissects the gallbladder and removes it with grasping forceps. This is a safe procedure with minimal morbidity.

Most patients have minimal postoperative pain and are discharged the day of surgery or the day after. They are usually able to resume normal activities and return to work within 1 week. The main complication is injury to the common bile duct. The

TABLE 44-21 COLLABORATIVE CARE

Cholelithiasis and Acute Cholecystitis

Diagnostic
- History and physical examination
- Ultrasound
- Endoscopic retrograde cholangiopancreatography (ERCP)
- Percutaneous transhepatic cholangiography
- Liver function studies
- White blood cell count
- Serum bilirubin

Collaborative Therapy

Conservative Therapy
- IV fluid
- NPO with NG tube, later progressing to low-fat diet
- Antiemetics
- Analgesics
- Fat-soluble vitamins (A, D, E, and K)
- Anticholinergics (antispasmodics)
- Antibiotics (for secondary infection)
- Transhepatic biliary catheter
- ERCP with sphincterotomy (papillotomy)
- Extracorporeal shock-wave lithotripsy

Dissolution Therapy
- ursodeoxycholic acid (ursodiol [Actigall])

Surgical Therapy
- Laparoscopic cholecystectomy
- Incisional (open) cholecystectomy

few contraindications to laparoscopic cholecystectomy include peritonitis, cholangitis, gangrene or perforation of the gallbladder, portal hypertension, and serious bleeding disorders.

On selected patients an incisional (open) cholecystectomy may be performed. This involves removal of the gallbladder through a right subcostal incision. A T tube may be inserted into the common bile duct during surgery when a common bile duct exploration is part of the surgical procedure (Fig. 44-16). This ensures patency of the duct until the edema produced by the trauma of exploring and probing the duct has subsided. It also allows the excess bile to drain while the small intestine is adjusting to receiving a continuous flow of bile.

Transhepatic Biliary Catheter. The transhepatic biliary catheter can be used preoperatively in biliary obstruction and in hepatic dysfunction secondary to obstructive jaundice. It can also be inserted for palliative care when inoperable liver, pancreatic, or bile duct carcinoma obstructs bile flow. The catheter is used when endoscopic drainage has been unsuccessful. The catheter is inserted percutaneously and allows for decompression of obstructed extrahepatic bile ducts so that bile can flow freely. After insertion, the catheter is connected to a drainage bag. The skin around the catheter insertion site is cleansed daily with an antiseptic. Observe for bile leakage at the insertion site. The patient may be discharged with it in place.

Drug Therapy. The most common drugs used in the treatment of gallbladder disease are analgesics, anticholinergics (antispasmodics), fat-soluble vitamins, and bile salts. Morphine may be used initially for pain management. NSAIDs (e.g., ketorolac) have also been shown to be helpful in pain management. Anticholinergics such as atropine and other antispasmodics may be used to relax the smooth muscle and decrease ductal tone.

If the patient has chronic gallbladder disease or any biliary tract obstruction, fat-soluble vitamins (A, D, E, and K) may need to be given. Bile salts may be administered to facilitate digestion and vitamin absorption.

Cholestyramine may provide relief from pruritus. Cholestyramine is a resin that binds bile salts in the intestine, increasing their excretion in the feces. It is administered in powder form, mixed with milk or juice. Side effects include nausea, vomiting, diarrhea or constipation, and skin reactions.

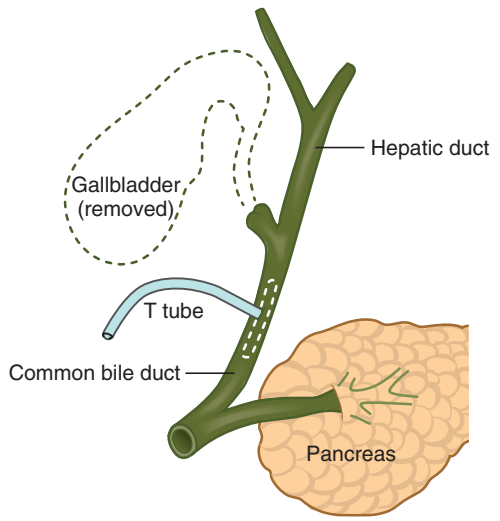

FIG. 44-16 Placement of T tube. *Dotted lines* indicate parts removed.

Nutritional Therapy. People have fewer problems if they eat smaller, more frequent meals with some fat at each meal to promote gallbladder emptying. If obesity is a problem, a reduced-calorie diet is indicated. The diet should be low in saturated fats (e.g., butter, shortening, lard) and high in fiber and calcium. Rapid weight loss should be avoided because it can promote gallstone formation.

After a laparoscopic cholecystectomy, instruct the patient to have liquids for the rest of the day and eat light meals for a few days. If an incisional cholecystectomy is done, the patient will progress from liquids to a regular diet once bowel sounds have returned. The amount of fat in the postoperative diet depends on the patient's tolerance of fat. A low-fat diet may be helpful if the flow of bile is reduced (usually only in the early postoperative period) or if the patient is overweight. Sometimes the patient is instructed to restrict fats for 4 to 6 weeks. Otherwise, no special dietary instructions are needed other than to eat nutritious meals and avoid excessive fat intake.

NURSING MANAGEMENT GALLBLADDER DISEASE

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a person with gallbladder disease are presented in Table 44-22.

TABLE 44-22 NURSING ASSESSMENT

Cholecystitis or Cholelithiasis

Subjective Data

Important Health Information

Past health history: Obesity, multiparity, infection, cancer, extensive fasting, pregnancy
Medications: Estrogen or oral contraceptives
Surgery or other treatments: Previous abdominal surgery

Functional Health Patterns

Health perception–health management: Positive family history; sedentary lifestyle
Nutritional-metabolic: Weight loss, anorexia; indigestion, fat intolerance, nausea and vomiting, dyspepsia; chills
Elimination: Clay-colored stools, steatorrhea, flatulence; dark urine
Cognitive-perceptual: Moderate to severe pain in right upper quadrant that may radiate to the back or scapula; pruritus

Objective Data

General

Fever, restlessness

Integumentary

Jaundice, icteric sclera; diaphoresis

Respiratory

Tachypnea, splinting during respirations

Cardiovascular

Tachycardia

Gastrointestinal

Palpable gallbladder, abdominal guarding and distention

Possible Diagnostic Findings

↑ Serum liver enzymes, alkaline phosphatase, and bilirubin; absence of urobilinogen in urine, ↑ urinary bilirubin; leukocytosis, abnormal gallbladder ultrasound

NURSING DIAGNOSES

Nursing diagnoses for the patient with gallbladder disease treated surgically include, but are not limited to, the following:

- Acute pain *related to* surgical procedure
- Ineffective self-health management *related to* lack of knowledge of diet and postoperative management

PLANNING

The overall goals are that the patient with gallbladder disease will have (1) relief of pain and discomfort, (2) no complications postoperatively, and (3) no recurrent attacks of cholecystitis or cholelithiasis.

NURSING IMPLEMENTATION

HEALTH PROMOTION. Be aware of predisposing factors for gallbladder disease in general health screening. Teach patients from ethnic groups in which the disease is more common, such as Native Americans, the initial manifestations and to see their health care provider if these manifestations occur. Patients with chronic cholecystitis may not have acute symptoms and may not seek help until jaundice and biliary obstruction occur. Earlier detection in these patients is beneficial so that they can be managed with a low-fat diet and monitored more closely.

ACUTE INTERVENTION. Nursing goals for the patient undergoing conservative therapy include treating pain, relieving nausea and vomiting, providing comfort and emotional support, maintaining fluid and electrolyte balance and nutrition, making accurate assessments to ensure effective treatment, and observing for complications.

The patient with acute cholecystitis or cholelithiasis frequently has severe pain. Give the drugs ordered to relieve the pain as required, before it becomes more severe. Assess what drugs relieve the pain and how much medication is required. Observe for side effects of the drugs as part of the continued assessment. Nursing comfort measures, such as a clean bed, comfortable positioning, and oral care, are appropriate.

Some patients have more severe nausea and vomiting than others. For these patients, it may be necessary to insert an NG tube and use gastric decompression. Eliminating intake of food and fluids also prevents further stimulation of the gallbladder. Oral hygiene, care of nares, accurate intake and output measurements, and maintenance of suction should be a part of the nursing care plan for this patient. For patients with less severe nausea and vomiting, antiemetics are usually adequate. When the patient is vomiting, provide comfort measures such as frequent mouth rinses. Remove any vomitus immediately from the patient's view.

If pruritus occurs with jaundice, measures to relieve itching are necessary (see earlier discussion on p. 1025 and eNCP 44-1).

Assess for progression of the symptoms and development of complications. Observe for signs of obstruction of the ducts by stones. These include jaundice; clay-colored stools; dark, foamy urine; steatorrhea; fever; and increased WBC count.

When manifestations of obstruction are present (see Table 44-20), bleeding may result from decreased prothrombin production. Common sites to observe for bleeding are the mucous membranes of the mouth, nose, gingivae, and injection sites. If injections are given, use a small-gauge needle and apply gentle pressure after the injection. Know the patient's prothrombin time and use it as a guide in the assessment process.

Assessment for infections includes monitoring vital signs. A temperature elevation with chills and jaundice may indicate choledocholithiasis.

Your care of the patient after ERCP with papillotomy includes assessment to detect complications such as pancreatitis, perforation, infection, and bleeding. Monitor the patient's vital signs. Abdominal pain and fever may indicate pancreatitis. The patient should be on bed rest for several hours and should be NPO until the gag reflex returns. Teach the patient the need for follow-up if the stent is to be removed or changed.

Postoperative Care. Postoperative nursing care after a laparoscopic cholecystectomy includes monitoring for complications such as bleeding, making the patient comfortable, and preparing the patient for discharge. A common postoperative problem is referred pain to the shoulder because of the carbon dioxide that is used to inflate the abdominal cavity during surgery. It may not be released or absorbed by the body. The carbon dioxide can irritate the phrenic nerve and the diaphragm, causing some difficulty in breathing. Placing the patient in the Sims' position (on left side with right knee flexed) helps move the gas pocket away from the diaphragm. Encourage deep breathing along with movement and ambulation. The pain can usually be relieved by NSAIDs or codeine. The patient is allowed clear liquids and can walk to the bathroom to void. Most patients go home the same day.

Postoperative nursing care for incisional cholecystectomy focuses on adequate ventilation and prevention of respiratory complications. Other nursing care is the same as general postoperative nursing care (see Chapter 20).

If the patient has a T tube (see Fig. 44-16), you need to maintain bile drainage and observe for T-tube functioning and drainage. The T tube is connected to a closed gravity drainage system. If the Penrose or Jackson-Pratt drain or the T tube is draining large amounts, it is helpful to use a sterile pouching system to protect the skin.

AMBULATORY AND HOME CARE. When the patient has conservative therapy, nursing management depends on the patient's symptoms and on whether surgical intervention is planned. Dietary teaching is usually necessary. The diet is usually low in fat, and sometimes a weight-reduction diet is also recommended. The patient may need to take fat-soluble vitamin supplements. Instruct the patient on observations that indicate obstruction (e.g., stool and urine changes, jaundice, pruritus). Explain the importance of continued health care follow-up.

The patient who undergoes a laparoscopic cholecystectomy is discharged soon after the surgery, so home care and teaching are important (Table 44-23).

After an incisional cholecystectomy, the patient is usually discharged in 2 or 3 days. Instruct the patient to avoid heavy lifting for 4 to 6 weeks. Usual sexual activities, including intercourse, can be resumed as soon as the patient feels ready, unless otherwise instructed by the health care provider.

Sometimes the patient is required to remain on a low-fat diet for 4 to 6 weeks. If so, an individualized dietary teaching plan is necessary. A weight-reduction program may be helpful if the patient is overweight. Most patients tolerate a regular diet with no difficulties but should avoid excessive fats.

EVALUATION

The overall expected outcomes are that the patient with gallbladder disease will

- Appear comfortable and verbalize pain relief
- Verbalize knowledge of activity level and dietary restrictions

GALLBLADDER CANCER

Primary cancer of the gallbladder is uncommon. The majority of gallbladder carcinomas are adenocarcinomas. Annually an estimated 9810 new cases of gallbladder cancer occur with an estimated 3200 deaths. A relationship exists between cancer of the gallbladder and chronic cholecystitis and cholelithiasis.

The early symptoms of carcinoma of the gallbladder are insidious and are similar to those of chronic cholecystitis and cholelithiasis, which makes the diagnosis difficult. Later symptoms are usually those of biliary obstruction. Gallbladder cancer is twice as common in women as in men.[35]

Diagnosis and staging of gallbladder cancer are done using EUS, abdominal ultrasound, CT, MRI, and/or MRCP. Unfortunately, gallbladder cancer often is not detected until the disease is advanced. When it is found early, surgery can be curative. Several factors influence successful surgical outcomes, including the depth of cancer invasion, extent of liver involvement, venous or lymphatic invasion, and lymph node metastasis. Extended cholecystectomy with lymph node dissection has improved the outcomes for patients with gallbladder cancer.

When surgery is not an option, endoscopic stenting of the biliary tree can be done to reduce obstructive jaundice. Adjuvant therapies, including radiation therapy and chemotherapy, may be used depending on the disease state. Overall, cancer of the gallbladder has a poor prognosis.

Nursing management involves palliative care with special attention to nutrition, hydration, skin care, and pain relief. Nursing care measures used for patients with cholecystitis and cholelithiasis are frequently applied, as well as nursing care measures for the patient with cancer (see Chapter 16).

TABLE 44-23 PATIENT & CAREGIVER TEACHING GUIDE

Postoperative Laparoscopic Cholecystectomy

Include the following instructions in the patient's postoperative teaching plan.

1. Remove the bandages on the puncture site the day after surgery and you can shower.
2. Notify your surgeon if any of the following signs and symptoms occurs:
   - Redness, swelling, bile-colored drainage or pus from any incision
   - Severe abdominal pain, nausea, vomiting, fever, chills
3. You can gradually resume normal activities.
4. Return to work within 1 wk of surgery.
5. You can resume your usual diet, but a low-fat diet is usually better tolerated for several weeks after surgery.

CASE STUDY

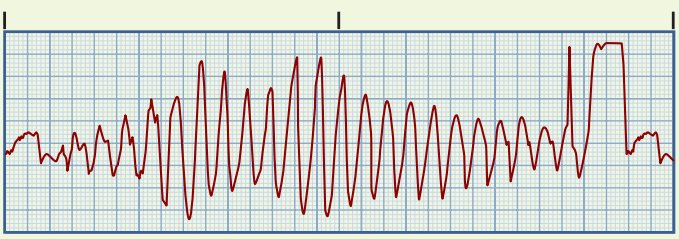
Cirrhosis of the Liver

Patient Profile

M.B. is a 55-yr-old Native American man admitted with a diagnosis of cirrhosis of the liver. He has been vomiting for 2 days and noticed blood in the toilet when he vomits.

Subjective Data

- Has had cirrhosis for 12 yr
- Acknowledges that he had been drinking heavily for 20 yr but has been sober for the past 2 yr
- Complains of anorexia, nausea, and abdominal discomfort



Objective Data

Physical Examination

- Thin and malnourished
- Has moderate ascites
- Has jaundice of sclera and skin
- Has 4+ pitting edema of the lower extremities
- Liver and spleen are palpable

Laboratory Values

- Total bilirubin: 15 mg/dL (257 mmol/L)
- AST: 190 U/L (3.2 μkat/L)
- ALT: 210 U/L (3.5 μkat/L)
- ECG is at right:

Discussion Questions

1. What are possible causes of cirrhosis? What type of cirrhosis does M.B. probably have?
2. Describe the pathophysiologic changes that occur in the liver as cirrhosis develops.
3. List M.B.'s clinical manifestations of liver failure. For each manifestation, explain the pathophysiologic basis.
4. Explain the significance of the results of his laboratory values and ECG findings.
5. If M.B. begins to manifest signs and symptoms of hepatic encephalopathy, what would you monitor? What measures should be instituted to control or decrease the encephalopathy?
6. What are possible causes of his gastrointestinal bleeding?
7. ***Priority Decision:*** Based on the assessment data, what are the priority nursing diagnoses? Are there any collaborative problems?
8. ***Priority Decision:*** What are the priority nursing interventions for the patient at this stage of his illness?
9. ***Evidence-Based Practice:*** M.B. discusses his prognosis with you. He says, "There is no hope. I might as well keep drinking." How would you respond to his question?

evolve Answers and corresponding concept map available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A patient with hepatitis A is in the acute phase. The nurse plans care for the patient based on the knowledge that
   a. pruritus is a common problem with jaundice in this phase.
   b. the patient is most likely to transmit the disease during this phase.
   c. gastrointestinal symptoms are not as severe in hepatitis A as they are in hepatitis B.
   d. extrahepatic manifestations of glomerulonephritis and polyarteritis are common in this phase.
2. A patient with acute hepatitis B is being discharged in 2 days. In the discharge teaching plan the nurse should include instructions to
   a. avoid alcohol for the first 3 weeks.
   b. use a condom during sexual intercourse.
   c. have family members get an injection of immunoglobulin.
   d. follow a low-protein, moderate-carbohydrate, moderate-fat diet.
3. A patient has been told that she has elevated liver enzymes caused by nonalcoholic fatty liver disease (NAFLD). The nursing teaching plan should include
   a. having genetic testing done.
   b. recommending a heart-healthy diet.
   c. the necessity to reduce weight rapidly.
   d. avoiding alcohol until liver enzymes return to normal.
4. The patient with advanced cirrhosis asks why his abdomen is so swollen. The nurse's response is based on the knowledge that
   a. a lack of clotting factors promotes the collection of blood in the abdominal cavity.
   b. portal hypertension and hypoalbuminemia cause a fluid shift into the peritoneal space.
   c. decreased peristalsis in the GI tract contributes to gas formation and distention of the bowel.
   d. bile salts in the blood irritate the peritoneal membranes, causing edema and pocketing of fluid.
5. In planning care for a patient with metastatic liver cancer, the nurse should include interventions that
   a. focus primarily on symptomatic and comfort measures.
   b. reassure the patient that chemotherapy offers a good prognosis.
   c. promote the patient's confidence that surgical excision of the tumor will be successful.
   d. provide information necessary for the patient to make decisions regarding liver transplantation.
6. Nursing management of the patient with acute pancreatitis includes *(select all that apply)*
   a. checking for signs of hypocalcemia.
   b. providing a diet low in carbohydrates.
   c. giving insulin based on a sliding scale.
   d. observing stools for signs of steatorrhea.
   e. monitoring for infection, particularly respiratory tract infection.
7. A patient with pancreatic cancer is admitted to the hospital for evaluation of possible treatment options. The patient asks the nurse to explain the Whipple procedure that the surgeon has described. The explanation includes the information that a Whipple procedure involves
   a. creating a bypass around the obstruction caused by the tumor by joining the gallbladder to the jejunum.
   b. resection of the entire pancreas and the distal portion of the stomach, with anastomosis of the common bile duct and the stomach into the duodenum.
   c. removal of part of the pancreas, part of the stomach, the duodenum, and the gallbladder, with joining of the pancreatic duct, the common bile duct, and the stomach into the jejunum.
   d. radical removal of the pancreas, the duodenum, and the spleen, and attachment of the stomach to the jejunum, which requires oral supplementation of pancreatic digestive enzymes and insulin replacement therapy.
8. The nursing management of the patient with cholecystitis associated with cholelithiasis is based on the knowledge that
   a. shock-wave therapy should be tried initially.
   b. once gallstones are removed, they tend not to recur.
   c. the disorder can be successfully treated with oral bile salts that dissolve gallstones.
   d. laparoscopic cholecystectomy is the treatment of choice in most patients who are symptomatic.
9. Teaching in relation to home management after a laparoscopic cholecystectomy should include
   a. keeping the bandages on the puncture sites for 48 hours.
   b. reporting any bile-colored drainage or pus from any incision.
   c. using over-the-counter antiemetics if nausea and vomiting occur.
   d. emptying and measuring the contents of the bile bag from the T tube every day.

1. a, 2. b, 3. b, 4. b, 5. a, 6. a, e, 7. c, 8. d, 9. b

CASE STUDY

Managing Multiple Patients

Introduction

You are working on the medical-surgical unit and have been assigned to care for the following five patients. You have one LPN who is assigned to help you and a UAP who is assigned to assist you and another RN.

Patients

iStockphoto/Thinkstock

L.C. is a 58-year-old Native American man admitted from the emergency department (ED) with acute abdominal pain. A CBC showed a Hgb of 9.0 g/dL and Hct of 26%. The WBC count is normal. A CT scan and colonoscopy indicated two medium-sized tumors in the transverse colon. A hemicolectomy was performed. The adenocarcinoma had spread to the muscle of the colon wall and there were two positive lymph nodes.

iStockphoto/Thinkstock

M.S. is a 70-year-old white woman who was recently admitted to the unit with generalized weakness and malnutrition. She is 5 feet 4 inches tall and weighs 100 lb, with a 30-lb weight loss in past 2 months. Her PMH includes a recent thrombotic stroke with hemiparesis and dysphagia. She has had nothing by mouth for the past 24 hours and just started enteral nutrition via PEG tube.

Hemera/Thinkstock

S.R. is a 48-year-old white woman admitted with complaints of chest pain and shortness of breath. She has a history of type 2 diabetes mellitus, hypertension, and osteoarthritis. She is 5 feet 4 inches tall and weighs 210 lb. Her most recent BP was 160/110 mm Hg. Her morning laboratory results reveal elevations in fasting blood glucose, total cholesterol, LDL cholesterol, and triglycerides. Her HDL cholesterol is low. Her cardiac enzymes and ECG are all within normal limits. She is scheduled to undergo a cardiac stress test at 10 AM.

iStockphoto/Thinkstock

F.H., a 40-year-old male immigrant from Vietnam, has a 1-year history of epigastric distress. He underwent an upper endoscopy a few weeks ago that revealed a duodenal ulcer and *H. pylori*. He was started on omeprazole, clarithromycin, and amoxicillin for 10 days. He came to the ED yesterday with complaints of severe epigastric pain. His Hgb was 8.2 g/dL and Hct was 24%. He was admitted and put on a pantoprazole (Protonix) continuous infusion and is scheduled for a repeat EGD today.

M.B. is a 55-year-old Native American man admitted with a diagnosis of upper GI bleeding. He has been vomiting for 2 days and noticed blood in the toilet when he vomits. He has had cirrhosis for 12 years and admits to drinking heavily for 20 years but has been sober for the past 2 years. He currently complains of anorexia, nausea, and abdominal discomfort. He is thin and malnourished, has moderate ascites, jaundice of sclera and skin, 4+ pitting edema of the lower extremities, and palpable liver and spleen. His bilirubin, serum ammonia level, and liver enzymes are all elevated. His morning laboratory test results demonstrate a Hct of 20% and Hgb of 6.8 g/dL.

Management Discussion Questions

1. ***Priority Decision:*** After receiving report, which patient should you see first? Provide a rationale for your decision.
2. ***Delegation Decision:*** Which tasks could you delegate to the LPN *(select all that apply)*?
   a. Assess L.C.'s pain level and bowel sounds.
   b. Administer oral medications to S.R. with a sip of water.
   c. Provide enteral tube feeding for M.S. if gastric residual <500 mL.
   d. Call M.B.'s health care provider regarding the morning laboratory results.
   e. Because she understands Vietnamese, teach F.H.'s wife about his disease.
3. ***Priority and Delegation Decision:*** As you are assessing M.B., the LPN informs you that F.H. just vomited a large amount of bright red blood. What initial action would be most appropriate?
   a. Have the LPN administer an antiemetic to F.H.
   b. Ask the LPN to notify F.H.'s health care provider.
   c. Leave M.B.'s room to perform a focused assessment on F.H.
   d. Ask the UAP to obtain a unit of packed red blood cells from the blood bank.

Case Study Progression

When you enter F.H.'s room, he tells you that his pain actually feels somewhat relieved since he vomited. However, you note that his skin is cool and clammy, his BP is 90/54 mm Hg, and his heart rate is 116 bpm. You notify his health care provider.

4. Which interventions would you expect the health care provider to order for F.H. *(select all that apply)?*
   a. Stat hemoglobin and hematocrit
   b. Emergent endoscopic and endotherapy
   c. Discontinue the pantoprazole (Protonix) infusion
   d. Start a second IV site and administer 500 mL normal saline over 30 minutes
5. ***Priority Decision:*** After administering a bolus feeding of enteral nutrition to M.S., it would be most important to
   a. assess for gastric residual.
   b. obtain an abdominal x-ray.
   c. keep head of bed elevated 30-45 degrees.
   d. record the total amount of fluid administered.
6. Which intervention to treat ascites might you expect the health care provider to order for M.B. *(select all that apply)?*
   a. Paracentesis
   b. Diuretic therapy
   c. 2 g sodium diet
   d. 1800 mL/day fluid restriction
   e. Shunt insertion from peritoneum to heart
7. ***Management Decision:*** As you enter the nurse's station, you overhear derogatory comments made by the UAP to the LPN about S.R.'s weight. Which response would be most appropriate?
   a. Report the incident to charge nurse for follow-up.
   b. Talk to the UAP to discuss possible HIPAA violation.
   c. Talk to S.R. to assess impact of UAP's bias on her self-image.
   d. Provide education to help staff members recognize obesity as a disease process.

LEARNING OUTCOMES

1. Differentiate among the anatomic location and functions of the kidneys, ureters, bladder, and urethra.
2. Explain the physiologic events involved in the formation and passage of urine from glomerular filtration to voiding.
3. Select significant subjective and objective data related to the urinary system that should be obtained from a patient.
4. Link the age-related changes of the urinary system to the differences in assessment findings.
5. Select appropriate techniques to use in the physical assessment of the urinary system.
6. Differentiate normal from abnormal findings of a physical assessment of the urinary system.
7. Describe the purpose, significance of results, and nursing responsibilities related to diagnostic studies of the urinary system.
8. Differentiate the normal from the abnormal findings of a urinalysis.

Adequate kidney function is essential to the maintenance of a healthy body. If a person has complete kidney failure and treatment is not provided, death is inevitable. This chapter discusses the structures and functions, assessment, and diagnostic studies of the urinary system.

STRUCTURES AND FUNCTIONS OF URINARY SYSTEM

The *upper urinary system* consists of two kidneys and two ureters. The *lower urinary system* consists of a urinary bladder and a urethra (Fig. 45-1). Urine is formed in the kidneys, drains through the ureters to be stored in the bladder, and then passes from the body through the urethra.

Kidneys

The kidneys are the principal organs of the urinary system. The primary functions of the kidneys are to (1) regulate the volume and composition of extracellular fluid (ECF) and (2) excrete waste products from the body. The kidneys also function to control blood pressure, produce erythropoietin, activate vitamin D, and regulate acid-base balance.

Macrostructure. The paired kidneys are bean-shaped organs located retroperitoneally (behind the peritoneum) on either side of the vertebral column at about the level of the twelfth thoracic (T12) vertebra to the third lumbar (L3) vertebra. Each kidney weighs 4 to 6 oz (113 to 170 g) and is about 5 in (12.5 cm) long. The right kidney, positioned at the level of the twelfth rib, is lower than the left. An adrenal gland lies on top of each kidney.

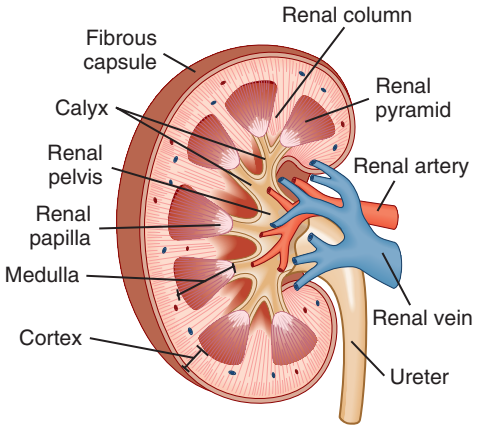

FIG. 45-2 Longitudinal section of the kidney.

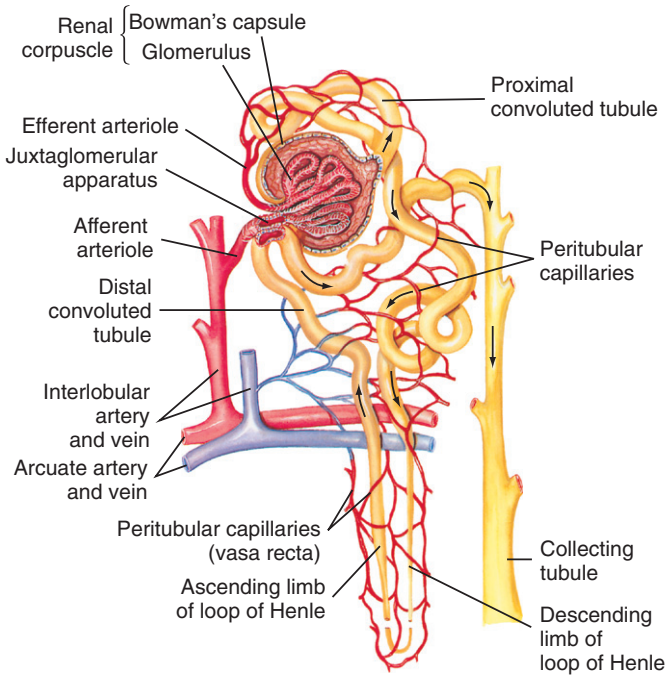

FIG. 45-3 The nephron is the basic functional unit of the kidney. This illustration of a single nephron unit also shows the surrounding blood vessels.

Each kidney is surrounded by a considerable amount of fat and connective tissue that cushions, supports, and maintains its position. A thin, smooth layer of fibrous membrane called the *capsule* covers the surface of each kidney. The capsule protects the kidney and serves as a shock absorber when this area is traumatized from a sudden force or strike. The *hilus* on the medial side of the kidney serves as the entry site for the renal artery and nerves, and as the exit site for the renal vein and ureter.

The parenchyma (actual tissue) of the kidney can be visualized on a longitudinal section of the kidney (Fig. 45-2). The outer layer is the *cortex,* and the inner layer is the *medulla.* The medulla consists of a number of pyramids. The apices (tops) of these pyramids are called *papillae,* through which urine passes to enter the calyces. The minor calyces widen and merge to form major calyces, which form a funnel-shaped sac called the *renal pelvis.* The minor and major calyces transport urine to the renal pelvis, from which it drains through the ureter to the bladder. The renal pelvis can store a small volume of urine (3 to 5 mL).

Microstructure. The **nephron** is the functional unit of the kidney. Each kidney contains approximately 1 million nephrons. Each nephron is composed of the glomerulus, Bowman's capsule, and a tubular system. The tubular system consists of the proximal convoluted tubule, loop of Henle, distal convoluted tubule, and collecting tubules (Fig. 45-3). The glomerulus, Bowman's capsule, proximal tubule, and distal tubule are located in the cortex of the kidney. The loop of Henle and collecting tubules are located in the medulla. Several collecting tubules join to form a single collecting duct. The collecting ducts eventually merge into a pyramid that empties via the papilla into a minor calyx.

Blood Supply. Blood flow to the kidneys, approximately 1200 mL/min, accounts for 20% to 25% of the cardiac output. Blood reaches the kidneys via the renal artery, which arises from the aorta and enters the kidney through the hilus. The renal artery divides into secondary branches and then into still smaller branches, each of which forms an afferent arteriole. The afferent arteriole divides into a capillary network, the **glomerulus,** which is a tuft of up to 50 capillaries (see Fig. 45-3). The capillaries of the glomerulus unite in the efferent arteriole. This efferent arteriole splits to form a capillary network, the peritubular capillaries, which surround the tubular system. All peritubular capillaries drain into the venous system; the renal vein empties into the inferior vena cava.

Physiology of Urine Formation. Urine formation is the outcome of a complex, multistep process of filtration, reabsorption, secretion, and excretion of water, electrolytes, and metabolic waste products. Although urine formation is the result of this process, the primary functions of the kidneys are to filter the blood and maintain the body's internal homeostasis.

Glomerular Function. Urine formation begins at the glomerulus, where blood is filtered. The glomerulus is a semipermeable membrane that allows filtration (see Fig. 45-3). The hydrostatic pressure of the blood within the glomerular capillaries causes a portion of blood to be filtered across the semipermeable membrane into Bowman's capsule, where the filtered portion of the blood (the glomerular filtrate) begins to pass down to the tubule. Filtration is more rapid in the glomerulus than in ordinary tissue capillaries because the glomerular membrane is porous. The ultrafiltrate is similar in composition to blood except that it lacks blood cells, platelets, and large plasma proteins. Under normal conditions, the capillary pores are too small to allow the loss of these large blood components. In many kidney diseases, capillary permeability is increased, which permits plasma proteins and blood cells to pass into the urine.

The amount of blood filtered each minute by the glomeruli is expressed as the **glomerular filtration rate (GFR).** The normal GFR is about 125 mL/min. The peritubular capillary network reabsorbs most of the glomerular filtrate before it reaches the end of the collecting duct. Therefore only 1 mL/min (on average) is excreted as urine.

Tubular Function. Since the glomerular membrane is a selective filtration membrane that filters primarily by size, provision is made for the reabsorption of essential materials and the excretion of nonessential ones (Table 45-1). The tubules and collecting ducts carry out these functions by means of reabsorption and secretion. *Reabsorption* is the passage of a substance from the lumen of the tubules through the tubule cells and into the capillaries. This process involves both active and passive transport mechanisms. Tubular *secretion* is the passage of a substance from the capillaries through the tubular cells into the lumen of the tubule. Reabsorption and secretion cause numerous changes in the composition of the glomerular filtrate as it moves through the entire length of the tubule.

In the proximal convoluted tubule, about 80% of the electrolytes are reabsorbed. Normally, all the glucose, amino acids, and small proteins are reabsorbed. Although most reabsorption occurs by active transport, hydrogen ions (H^+) and creatinine are secreted into the filtrate.

As reabsorption continues in the loop of Henle, water is conserved, which is important for concentrating the filtrate. The descending loop is permeable to water and moderately permeable to sodium, urea, and other solutes. In the ascending limb, chloride ions (Cl^-) are actively reabsorbed, followed by passive reabsorption of sodium ions (Na^+). About 25% of the filtered sodium is reabsorbed in the ascending limb.

Two important functions of the distal convoluted tubules are final regulation of water balance and acid-base balance. Antidiuretic hormone (ADH) is required for water reabsorption in the kidney and is important in water balance. ADH makes the distal convoluted tubules and the collecting ducts permeable to water. This allows water to be reabsorbed into the peritubular capillaries and eventually returned to the circulation.

Decreases in plasma osmolality are detected in the anterior hypothalamus by osmoreceptors. These osmoreceptors send neural input to *superoptic nuclei cells* in the hypothalamus. These superoptic nuclei cells have neuronal axons that terminate in the posterior pituitary gland and act to inhibit secretion of ADH. In the absence of ADH, the tubules are essentially impermeable to water. Thus any water in the tubules leaves the body as urine.

Aldosterone (released from the adrenal cortex) acts on the distal tubule to cause reabsorption of Na^+ and water. In exchange for Na^+, potassium ions (K^+) are excreted. The secretion of aldosterone is influenced by both circulating blood volume and plasma concentrations of Na^+ and K^+.

Acid-base regulation involves reabsorbing and conserving most of the bicarbonate (HCO_3^-) and secreting excess H^+. The distal tubule has different ways to maintain the pH of ECF within a range of 7.35 to 7.45 (see Chapter 17).

Myocyte cells in the right atrium secrete a hormone, atrial natriuretic peptide (ANP), in response to atrial distention, which is a result of an increase in plasma volume. ANP acts on the kidneys to increase sodium excretion. At the same time ANP inhibits renin, ADH, and the action of angiotensin II on the adrenal glands, thereby suppressing aldosterone secretion. These combined effects of ANP result in the production of a large volume of dilute urine. Furthermore, secretion of ANP causes relaxation of the afferent arteriole, thus increasing the GFR.

The renal tubules are also involved in calcium balance. Parathyroid hormone (PTH) is released from the parathyroid gland in response to low serum calcium levels. PTH maintains serum calcium levels by causing increased tubular reabsorption of calcium ions (Ca^{2+}) and decreased tubular reabsorption of phosphate ions (PO_4^{2-}). In kidney disease the effects of PTH may have a major effect on bone metabolism.

Vitamin D is a hormone that can be obtained in the diet or synthesized by the action of ultraviolet radiation on cholesterol in the skin. These forms of vitamin D are inactive and require two more steps to become metabolically active. The first step in activation occurs in the liver; the second step occurs in the kidneys. Active vitamin D is essential for the absorption of calcium from the gastrointestinal (GI) tract. The patient with kidney failure (also called renal failure) has a deficiency of the active metabolite of vitamin D and manifests problems of altered calcium and phosphate balance (see Chapter 47).

In summary, the basic function of nephrons is to cleanse blood plasma of unnecessary substances. After the glomerulus

TABLE 45-1 FUNCTIONS OF NEPHRON SEGMENTS

Component	Function
Glomerulus	Selective filtration.
Proximal tubule	Reabsorption of 80% of electrolytes and water, glucose, amino acids, HCO_3^-. Secretion of H^+ and creatinine.
Loop of Henle	Reabsorption of Na^+ and Cl^- in ascending limb and water in descending loop. Concentration of filtrate.
Distal tubule	Secretion of K^+, H^+, ammonia. Reabsorption of water (regulated by ADH) and HCO_3^-. Regulation of Ca^{2+} and PO_4^{2-} by parathyroid hormone. Regulation of Na^+ and K^+ by aldosterone.
Collecting duct	Reabsorption of water (ADH required).

ADH, Antidiuretic hormone.

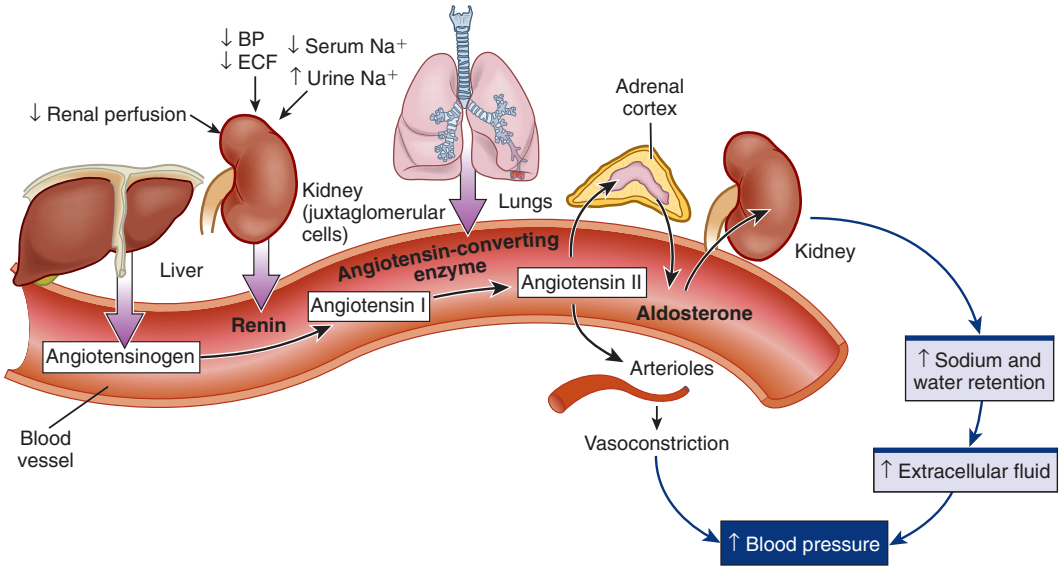

FIG. 45-4 Renin-angiotensin-aldosterone system.

has filtered the blood, the tubules select the unwanted from the wanted portions of tubular fluid. Essential constituents are returned to the blood, and dispensable substances pass into urine.

Other Functions of Kidneys. The kidneys perform vital functions through participation in red blood cell (RBC) production and blood pressure regulation. Erythropoietin is a hormone produced in the kidneys and secreted in response to hypoxia and decreased renal blood flow. Erythropoietin stimulates RBC production in the bone marrow. A deficiency of erythropoietin occurs in kidney failure, leading to anemia.

Renin is important in the regulation of blood pressure. Renin is produced and secreted by the kidney's juxtaglomerular cells (Fig. 45-4). Renin is released into the bloodstream in response to decreased renal perfusion, decreased arterial blood pressure, decreased ECF, decreased serum Na^+ concentration, and increased urinary Na^+ concentration. The plasma protein angiotensinogen (from the liver) is activated to angiotensin I by renin. Angiotensin I is subsequently converted to angiotensin II by angiotensin-converting enzyme (ACE). ACE is located on the inner surface of all blood vessels, with particularly high levels in the vessels of the lungs. Angiotensin II stimulates the release of aldosterone from the adrenal cortex, which causes Na^+ and water retention, leading to increased ECF volume. Angiotensin II also causes increased peripheral vasoconstriction. Release of renin is inhibited by an elevation in blood pressure. Excessive renin production caused by impaired renal perfusion may be a contributing factor in the etiology of hypertension (see Chapters 33 and 47).

Most body tissues synthesize prostaglandins (PGs) from the precursor, arachidonic acid, in response to appropriate stimuli. (See Chapter 12 and Fig. 12-2 for a more detailed discussion of PGs.) In the kidney, PG synthesis (primarily PGE_2 and PGI_2) occurs primarily in the medulla. These PGs have a vasodilating action, thus increasing renal blood flow, and promote Na^+ excretion. They counteract the vasoconstrictor effect of substances such as angiotensin and norepinephrine. Renal PGs may have a systemic effect in lowering blood pressure by decreasing systemic vascular resistance. The significance of renal PGs is related to the kidneys' role in causing hypertension. In renal failure with a loss of functioning tissue, these renal vasodilator factors are also lost, which may contribute to hypertension (see Chapter 47).

Ureters

The ureters are tubes that carry urine from the renal pelvis to the bladder (see Fig. 45-1). Arranged in a meshlike outer layer, circular and longitudinal smooth muscle fibers contract to promote the peristaltic, one-way flow of urine through the ureters. Distention, neurologic and endocrine influences, and drugs can affect these muscle contractions. Each ureter is approximately 10 to 12 in (25 to 30.5 cm) long and 0.08 to 0.3 in (0.2 to 0.8 cm) in diameter.

The narrow area where each ureter joins the renal pelvis is termed the *ureteropelvic junction* (UPJ). Subsequently, the ureters insert into either side of the bladder base at the *ureterovesical junctions* (UVJs). Ureteral lumens are narrowest at the UVJs. These junctions, the UPJ and UVJ, are often sites of obstruction. The narrow ureteral lumens can be easily obstructed internally (e.g., urinary calculi) or externally (e.g., tumors, adhesions, inflammation). Sympathetic and parasympathetic nerves, along with the vascular supply, surround the mucosal lining of the ureters. Stimulation of these nerves during passage of a stone or clot may cause acute, severe pain, termed *renal colic.*

Because the renal pelvis holds only 3 to 5 mL of urine, kidney damage can result from a backflow of more than that amount of urine. The UVJ relies on the ureter's angle of bladder penetration and muscle fiber attachments with the bladder to prevent the backflow *(reflux)* of urine and ascending infection. The distal ureter enters the bladder laterally at its base, courses along obliquely through the bladder wall for about 1.5 cm, and intermingles with muscle fibers of the bladder base. Circular and longitudinal bladder muscle fibers adjacent to the imbedded ureter help secure it. When bladder pressure rises (e.g., during voiding or coughing), muscle fibers that the ureter shares with the bladder base contract first, promoting ureteral lumen closure. Next, the bladder contracts against its base, ensuring UVJ closure and prevention of urine reflux through the junction.

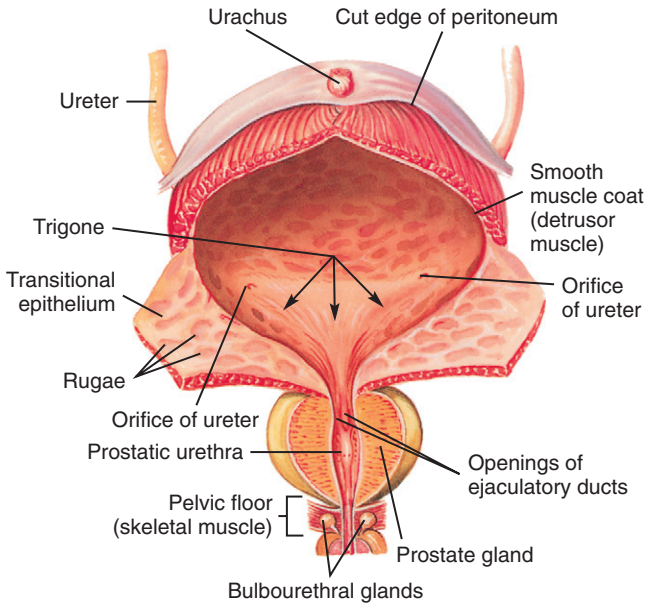

FIG. 45-5 Urinary bladder of a male.

Bladder

The urinary bladder is a stretchable (able to fill at relatively low pressures) organ positioned behind the symphysis pubis and anterior to the vagina and rectum (Fig. 45-5). Its primary functions are to serve as a reservoir for urine and to eliminate waste products from the body. Normal adult urine output is approximately 1500 mL/day, which varies with food and fluid intake. The volume of urine produced at night is less than half of that formed during the day because of hormonal influences (e.g., ADH). This diurnal pattern of urination is normal. Typically, an individual will urinate five or six times during the day and occasionally at night.

The *trigone* is the triangular area formed by the two ureteral openings and the bladder neck at the base of the bladder. The trigone is affixed to the pelvis by many ligaments and does not change its shape during bladder filling or emptying. The bladder muscle *(detrusor)* is composed of layers of intertwined smooth muscle fibers capable of considerable distention during bladder filling and contraction during emptying. It is attached to the abdominal wall by an umbilical ligament, the *urachus.* As a result of this attachment, as the bladder fills, it rises toward the umbilicus. The dome and the anterior and lateral aspects of the bladder expand and contract.

On average, 200 to 250 mL of urine in the bladder cause moderate distention and the urge to urinate. When the quantity of urine reaches approximately 400 to 600 mL, the person feels uncomfortable. Bladder capacity varies with the individual, but generally ranges from 600 to 1000 mL. Evacuation of urine is termed *urination, micturition,* or *voiding.*

The bladder has the same mucosal lining as that of the renal pelvises, ureters, and bladder neck. The bladder is lined by transitional cell epithelium and is referred to as the *urothelium*. The urothelium is unique to the urinary tract. Transitional cell epithelium is resistant to absorption of urine. Therefore urinary wastes produced by the kidneys do not leak out of the urinary system after they leave the kidneys. Microscopically, transitional cell epithelium is several cells deep. However, as urine enters the bladder, these cells stretch out to only a few cells deep to accommodate filling. As the bladder empties, the urothelium resumes its multicellular layer formation.

Transitional cell tumors occurring in one section of the urinary tract can easily metastasize to other urinary tract areas given that the mucosal lining throughout the urinary tract is the same. Malignant cells may move down from upper urinary tract tumors and embed in the bladder, or large bladder tumors can invade the ureter. Tumor recurrence within the bladder is common.

Urethra

The urethra is a small tube that incorporates the smooth muscle of the bladder neck and extends to the striated muscle of the external meatus. The urethra's primary function is to serve as a conduit for urine from the bladder to the outside the body during voiding and to control voiding.

The female urethra is 1 to 2 in (2.5 to 5 cm) long and lies behind the symphysis pubis but anterior to the vagina (see Fig. 45-1, *C*). The male urethra, which is about 8 to 10 in (20 to 25 cm) long, originates at the bladder neck and extends the length of the penis (see Fig. 45-1, *B*).

Urethrovesical Unit

Together, the bladder, urethra, and pelvic floor muscles form what is called the urethrovesical unit. Voluntary control of this unit is defined as *continence.* Stimulating and inhibiting impulses are sent from the brain through the thoracolumbar (T11 to L2) and sacral (S2 to S4) areas of the spinal cord to control voiding. Distention of the bladder stimulates stretch receptors within the bladder wall. Impulses are transmitted to the sacral spinal cord and then to the brain, causing a desire to urinate. If the time to void is not appropriate, inhibitor impulses in the brain are stimulated and transmitted back through the thoracolumbar and sacral nerves innervating the bladder. In a coordinated fashion, the detrusor muscle accommodates to the pressure (does not contract) while the sphincter and pelvic floor muscles tighten (contract) to resist bladder pressure. If voiding is appropriate, cerebral inhibition is voluntarily suppressed, and impulses are transmitted via the spinal cord for the bladder neck, sphincter, and pelvic floor muscles to relax and for the bladder to contract. The sphincter closes and the detrusor muscle relaxes when the bladder is empty.

Any disease or trauma that affects the function of the brain, spinal cord, or nerves that directly innervate the bladder, bladder neck, external sphincter, or pelvic floor can affect bladder function. These conditions include diabetes mellitus, multiple sclerosis, paraplegia, and tetraplegia (quadriplegia). Drugs affecting nerve transmission also can affect bladder function.

GERONTOLOGIC CONSIDERATIONS

EFFECTS OF AGING ON URINARY SYSTEM

Anatomic changes in the aging kidney include a 20% to 30% decrease in size and weight between ages 30 and 90 years. By the seventh decade of life, 30% to 50% of glomeruli have lost their function. Atherosclerosis accelerates the decrease of renal size with age. Despite these changes, older individuals maintain body fluid homeostasis unless they encounter diseases or other physiologic stressors.[1]

Physiologic changes in the aging kidney include decreased renal blood flow, due in part to atherosclerosis, resulting in a

TABLE 45-2 GERONTOLOGIC ASSESSMENT DIFFERENCES

Urinary System

Gerontologic Changes	Differences in Assessment Findings
Kidney	
• ↓ Amount of renal tissue	• Less palpable
• ↓ Number of nephrons and renal blood vessels; thickened basement membrane of Bowman's capsule and glomeruli	• ↓ Creatinine clearance, ↑ BUN level, ↑ serum creatinine
• ↓ Function of loop of Henle and tubules	• Alterations in drug excretion, nocturia, loss of normal diurnal excretory pattern because of ↓ ability to concentrate urine; less concentrated urine
Ureter, Bladder, and Urethra	
• ↓ Elasticity and muscle tone	• Palpable bladder after urination because of retention
• Weakening of urinary sphincter	• Stress incontinence (especially during Valsalva maneuver), dribbling of urine after urination
• ↓ Bladder capacity and sensory receptors	• Frequency, urgency, nocturia, overflow incontinence
• Estrogen deficiency leading to thin, dry vaginal tissue	• Stress or overactive bladder, dysuria
• ↑ Prevalence of unstable bladder contractions	• Overactive bladder
• Prostatic enlargement	• Hesitancy, frequency, urgency, nocturia, straining to urinate, retention, dribbling

decreased GFR. Alterations in hormone levels, including ADH, aldosterone, and ANP, result in decreased urinary concentrating ability and alterations in the excretion of water, sodium, potassium, and acid. Under normal conditions, the aging kidney is able to maintain homeostasis. However, after abrupt changes in blood volume, acid load, or other insults, the kidney may not be able to function effectively because much of its renal reserve has been lost.

Physiologic changes also occur in the aging urethra and bladder. The female urethra, bladder, vagina, and pelvic floor undergo a loss of elasticity and muscle support. Consequently, older women are more prone to bladder infections and incontinence.

The prostate surrounds the proximal urethra. As men age, the prostate enlarges and may affect urinary patterns, causing hesitancy, retention, slow stream, and bladder infections.[2]

Constipation, a complaint often expressed by older adults, can also affect urination. Partial urethral obstruction may occur because of the rectum's close proximity to the urethra.

Age-related changes in the urinary system and differences in assessment findings are presented in Table 45-2.

ASSESSMENT OF URINARY SYSTEM

Subjective Data

Important Health Information

Past Health History. Question the patient about the presence or history of diseases that are related to renal or other urologic problems. Some of these diseases are hypertension, diabetes mellitus, gout and other metabolic problems, connective tissue disorders (e.g., systemic lupus erythematosus, systemic sclerosis [scleroderma]), skin or upper respiratory tract infections of streptococcal origin, tuberculosis, viral hepatitis, congenital disorders, neurologic conditions (e.g., stroke, back injury), or trauma. Note specific urinary problems such as cancer, infections, benign prostatic hyperplasia, and calculi.

FOCUSED ASSESSMENT

Urinary System

Use this checklist to ensure that the key assessment steps have been done.

Subjective

Ask the patient about any of the following and note responses.

Painful urination	Y	N
Changes in color of urine (blood, cloudy)	Y	N
Change in characteristics of urination (diminished, excessive)	Y	N
Problems with frequent nighttime urination (nocturia)	Y	N

Objective: Diagnostic

Check the following laboratory results for critical values.

Blood urea nitrogen	✓
Serum creatinine	✓
Urinalysis	✓
Urine culture and sensitivity	✓

Objective: Physical Examination

Inspect

Abdomen	✓
Urinary meatus for inflammation or discharge	✓

Palpate

Abdomen for bladder distention, masses, or tenderness	✓

Percuss

Costovertebral angle for tenderness	✓

Auscultate

Renal arteries for bruits	✓

CASE STUDY

Patient Introduction

iStockphoto/Thinkstock

A.K. is a 28-yr-old African American man who comes to the emergency department (ED) in acute distress with complaints of severe abdominal pain. The pain began about 6 hr ago after he finished a 10-mile run as part of his training for a marathon. He says that the pain has steadily increased, he is nauseated, and his urine is a dark, smoky color.

Critical Thinking

As you read through this assessment chapter, think about A.K.'s symptoms with the following questions in mind:

1. What are the possible causes of A.K.'s abdominal pain, nausea, and urine color?
2. What would be your priority assessment of A.K.?
3. What questions would you ask A.K.?
4. What should be included in the physical assessment? What would you be looking for?
5. What diagnostic studies might you expect to be ordered?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

TABLE 45-3 POTENTIALLY NEPHROTOXIC AGENTS

Antibiotics	Other Drugs	Other Agents
amikacin (Amikin)	captopril (Capoten)	Gold
amphotericin B	cimetidine (Tagamet)	Heavy metals
bacitracin	cisplatin (Platinol)	
cephalosporins	cocaine	
gentamicin	cyclosporine	
kanamycin	ethylene glycol	
neomycin	heroin	
polymyxin B	lithium	
streptomycin	methotrexate	
sulfonamides	nitrosoureas (e.g., carmustine)	
tobramycin (Nebcin)	Nonsteroidal antiinflammatory drugs (e.g., ibuprofen, indomethacin)	
vancomycin	phenacetin	
	quinine	
	rifampin	
	Salicylates (large quantities)	

Medications. An assessment of the patient's current and past use of medications is important. This should include over-the-counter drugs, prescription medications, and herbs. Drugs affect the urinary tract in several ways. Many drugs are known to be nephrotoxic (Table 45-3). Certain drugs may alter the quantity and character of urine output (e.g., diuretics). A number of drugs such as phenazopyridine (Pyridium) and nitrofurantoin (Macrodantin) change the color of urine. Anticoagulants may cause hematuria. Many antidepressants, calcium channel blockers, antihistamines, and drugs used for neurologic and musculoskeletal disorders affect the ability of the bladder or sphincter to contract or relax normally.

Surgery or Other Treatments. Ask the patient about previous hospitalizations related to renal or urologic diseases and all urinary problems during past pregnancies. Inquire about the duration, severity, and patient's perception of any problem and its treatment. Document past surgeries, particularly pelvic surgeries, or urinary tract instrumentation (e.g., catheterization). Ask the patient about any radiation or chemotherapy treatment for cancer.

Functional Health Patterns. Key questions to ask a patient with problems related to the renal system are listed in Table 45-4.

TABLE 45-4 HEALTH HISTORY

Urinary System

Health Perception–Health Management
- How is your energy level compared with 1 yr ago?
- Do you notice any visual changes?*
- Have you ever smoked? If yes, how many packs per day?

Nutritional-Metabolic
- How is your appetite?
- Has your weight changed over the past yr?*
- Do you take vitamins, herbs, or any other supplements?*
- How much and what kinds of fluids do you drink daily?
- How many dairy products and how much meat do you eat?
- Do you drink coffee? Colas? Tea?
- Do you eat chocolate?
- Do you spice your food heavily?*

Elimination
- Are you able to sit through a 2-hr meeting or ride in a car for 2 hr without urinating?
- Do you awaken at night with the desire to urinate? If so, how many times does this occur during an average night?
- Do you ever notice blood in your urine?* If so, at what point in the urination does it occur?
- Do you ever pass urine when you do not intend to? When?
- Do you use special devices or supplies for urine elimination or control?*
- How often do you move your bowels?
- Do you ever experience constipation?
- Do you frequently experience diarrhea? Do you ever have problems controlling your bowels? If so, do you have problems controlling the passage of gas? Watery or liquid stool? Solid stool?

Activity-Exercise
- Have you noticed any changes in your ability to do your usual daily activities?*
- Do certain activities aggravate your urinary problem?*
- Has your urinary problem caused you to alter or stop any activity or exercise?*
- Do you require assistance in moving or getting to the bathroom?*

Sleep-Rest
- Do you awaken at night from an urge to urinate?*
- Do you awaken at night from pain or other problems and urinate as a matter of routine before returning to sleep?*
- Do you experience daytime sleepiness and fatigue as a result of nighttime urination?*

Cognitive-Perceptual
- Do you ever have pain when you urinate?* If so, where is the pain?

Self-Perception–Self-Concept
- How does your urinary problem make you feel about yourself?
- Do you perceive your body differently since you have developed a urinary problem?

Role-Relationship
- Does your urinary problem interfere with your relationships with family or friends?*
- Has your urinary problem caused a change in your job status or affected your ability to carry out job-related responsibilities?*

Sexuality-Reproductive
- Has your urinary problem caused any change in your sexual pleasure or performance?*
- Do you have hygiene problems related to sexual activities that cause you concern?*

Coping–Stress Tolerance
- Do you feel able to manage the problems associated with your urinary problem? If not, explain.
- What strategies are you using to cope with your urinary problem?

Values-Beliefs
- Has your present illness affected your belief system?*
- Are your treatment decisions related to your urinary problem in conflict with your value system?*

*If yes, describe.

Health Perception–Health Management Pattern. Ask about the patient's general health, particularly when a disorder affecting the kidneys is suspected. Abnormal kidney function may be suggested by changes in weight or appetite; excess thirst; fluid retention; and complaints of headache, pruritus, blurred vision, or "feeling tired all the time." Similarly, an older patient may report malaise and nonlocalized abdominal discomfort as the only symptoms of a urinary tract infection (UTI). Family members may report disorientation or increased confusion that may be a sign of UTI in older adults.

Take an occupational history because exposure to certain chemicals can affect the kidneys and urinary system. Phenol and ethylene glycol are examples of nephrotoxic chemicals. Aromatic amines and some organic chemicals may increase the risk of bladder cancers. Textile workers, painters, hairdressers, and industrial workers have a high incidence of bladder tumors.

Get a smoking history. Cigarette smoking is a major risk factor for bladder cancer. Tumors occur more frequently in cigarette smokers than in nonsmokers.

Obtain information about places where a patient has lived. It has been shown that persons living in certain parts of the United States (Great Lakes, Southwest, Southeast) have a higher than normal incidence of urinary calculi, possibly caused by the higher mineral content of the soil and water. A person living in Middle Eastern countries or Africa can acquire certain parasites that can cause cystitis or bladder cancer.

GENETIC RISK ALERT

- Polycystic kidney disease and congenital urinary tract abnormalities (e.g., Alport syndrome [congenital nephritis]) are genetic disorders.
- A family history of certain renal or urologic problems increases the likelihood of similar problems occurring in the patient.
- Ask about family members who have had any of the diseases that the patient mentions in the past health history.

Nutritional-Metabolic Pattern. The usual quantity and types of fluid a patient drinks are important in relation to urinary tract disease. Dehydration may contribute to UTIs, calculi formation, and kidney failure. Large intake of particular foods, such as dairy products or foods high in proteins, may also lead to calculi formation. Asparagus may cause the urine to smell musty, and red urine caused by beet ingestion may be mistaken for bloody urine. Caffeine, alcohol, carbonated beverages, some artificial sweeteners, or spicy foods often aggravate urinary inflammatory diseases. Green tea and some herbal teas also cause diuresis. An unexplained weight gain may be the result of fluid retention secondary to a renal problem. Anorexia, nausea, and vomiting can dramatically affect fluid status and require careful assessment. Obtain information on vitamin and mineral supplements and herbal therapies. The patient may not think of these supplements and therapies when listing over-the-counter drugs.

Elimination Pattern. Questions about urine elimination patterns are the cornerstone of the health history in the patient with a lower urinary tract disorder. This line of inquiry begins with a question of how the patient manages urine elimination. Most patients eliminate urine by spontaneous voiding. Therefore ask about daytime (diurnal) voiding frequency and the frequency of nocturia. Pelvic organ prolapse, particularly advanced anterior vaginal prolapse, may cause suprapubic pressure, frequency, urgency, and incontinence secondary to urinary retention. Query patients about additional bothersome lower urinary tract symptoms, including urgency, incontinence, or urinary retention. Table 45-5 lists some of the common manifestations of urinary tract disorders.

CASE STUDY—cont'd

Subjective Data

iStockphoto/Thinkstock

A focused subjective assessment of A.K. revealed the following information:

PMH: History of one isolated incidence of possible gout 6 yr ago. He stopped drinking alcohol with no further occurrence. Appendectomy 12 yr ago.

Medications: None.

Health Perception–Health Management: A.K. states that he is usually healthy. He does not smoke or drink alcohol. He has never experienced this type of pain before. Describes the pain as being sharp and colicky (coming in waves). Rates the pain as 9 on a scale of 0-10.

Nutritional-Metabolic: A.K. is currently on a high-protein diet as he trains for the marathon. He eats a lot of chicken, beef, and seafood. He drinks milk-based protein shakes and water after exercising but admits that he does not think he drinks enough to replace fluid loss in perspiration. He drinks coffee for energy but denies eating chocolate or other sweets. He also avoids sodas.

Elimination: Denies any history of difficulty with urination or constipation or diarrhea. This is the first time he has ever noticed a change of color in his urine.

Activity-Exercise: Prides himself in his ability to exercise and run without difficulty.

Sleep-Rest: Does not awaken at night to urinate.

Cognitive-Perceptual: Denies pain on urination.

Self-Perception–Self-Concept: Believes he is able to monitor self and maintain healthy lifestyle.

Coping–Stress Tolerance: Worried that this pain may interfere with his marathon training.

TABLE 45-5 MANIFESTATIONS OF URINARY SYSTEM DISORDERS

	Specific Manifestations Related to Urinary System				
General Manifestations	**Edema**	**Pain**	**Patterns of Urination**	**Urine Output**	**Urine Composition**
Fatigue Headaches Blurred vision Elevated blood pressure Anorexia Nausea and vomiting Chills Itching Excessive thirst Change in body weight Cognitive changes	Facial (periorbital) Ankle Ascites Anasarca Sacral	Dysuria Flank or costovertebral angle Groin Suprapubic	Frequency Urgency Hesitancy of stream Change in stream Retention Dysuria Nocturia Incontinence Stress incontinence Dribbling	Anuria Oliguria Polyuria	Concentrated Dilute Hematuria Pyuria Color (red, brown, yellowish green)

Changes in the color and appearance of urine are often significant and should be evaluated. If blood is visible in the urine, determine if it occurs at the beginning of, throughout, or at the end of urination.

Investigate bowel function. Problems with fecal incontinence may signal neurologic causes for bladder problems because of shared nerve pathways. Constipation and fecal impaction can partially obstruct the urethra, causing inadequate bladder emptying, overflow incontinence, and infection.

Determine the patient's method of handling a urinary problem. A patient may already be using a catheter or collection device. Sometimes a patient has to assume a particular position to urinate or perform maneuvers such as pressing on the lower abdomen (Credé's method) or straining (Valsalva maneuver) to empty the bladder.

Activity-Exercise Pattern. Assess the patient's level of activity. A sedentary person is more likely to have stasis of urine than an active individual and thus can be predisposed to infection and calculi. Demineralization of bones in an individual with limited physical activity can cause increased urine calcium precipitation.

An active person may find that increasing activity aggravates the urinary problem. The patient who has had prostate surgery or who has weakened pelvic floor muscles may leak urine when attempting particular activities such as running. Some men develop chronic inflammatory prostatitis or epididymitis after heavy lifting or long-distance driving.

Sleep-Rest Pattern. Nocturia is a common and a particularly bothersome lower urinary tract symptom that often leads to sleep deprivation, daytime sleepiness, and fatigue. It occurs in multiple disorders affecting the lower urinary tract, including urinary incontinence, urinary retention, and interstitial cystitis. Nocturia also may be related to polyuria secondary to kidney disease, poorly controlled diabetes mellitus, alcoholism, excessive fluid intake, or obstructive sleep apnea.[3]

When assessing nocturia, determine whether the need to urinate causes the person to arise from sleep or whether pain or some other symptom interrupts sleep and the person urinates as a matter of habit before returning to bed. Up to one episode of nocturia is considered normal in younger adults, and up to two episodes are acceptable among adults ages 65 years or older. If the older adult has more than two voidings during the night, assess the amount and timing of fluid intake. This information will help determine whether further investigation is needed.

Cognitive-Perceptual Pattern. Level of mobility, visual acuity, and dexterity are important factors to determine for a patient with urologic problems when managing his or her own care at home, particularly when urine retention or incontinence is a problem. Determine if the patient is alert, is able to understand instructions, and can recall the instructions when necessary.

If urinary incontinence is present, elicit a thorough history of the problem to help determine the type of incontinence. Document what the patient has previously tried to manage the problem. Incontinence is a distressing problem and calls for great sensitivity on your part to obtain accurate information.

A frequent symptom of renal and urologic problems is pain, including dysuria, groin pain, costovertebral pain, and suprapubic pain. Assess pain and document the location, character, and duration. The absence of pain when other urinary symptoms exist is also significant. Many urinary tract tumors are painless in the early stages.

Self-Perception–Self-Concept Pattern. Problems associated with the urinary system, such as incontinence, urinary diversion procedures, and chronic fatigue (may indicate anemia), can result in loss of self-esteem and a negative body image.

Role-Relationship Pattern. Urinary problems can affect many aspects of a person's life, including the ability to work and relationships with others. These factors have important implications for future treatment and management of the patient's condition.

Urinary system problems may be serious enough to cause problems in job-related and social situations. Chronic dialysis therapy often makes regular employment or full-time homemaking difficult. Concurrent poor health and negative body image can seriously alter existing roles.

Sexuality-Reproductive Pattern. Question the patient about the effect of a renal or urologic problem on her or his sexual patterns and satisfaction. Problems related to personal hygiene and fatigue can seriously affect a sexual relationship. Although urinary incontinence is not directly associated with sexual dysfunction, it often has a devastating effect on self-esteem and social and intimate relationships. Counseling of both the patient and partner may be indicated.

Objective Data

Physical Examination

Inspection. Assess for changes in the following:

Skin: Pallor, yellow-gray cast, excoriations, changes in turgor, bruises, texture (e.g., rough, dry skin) (see Table 23-6 for assessment of dark-skinned individuals)

Mouth: Stomatitis, ammonia breath odor

Face and extremities: Generalized edema, peripheral edema, bladder distention, masses, enlarged kidneys

Abdomen: Skin changes described earlier, striae, abdominal contour for midline mass in lower abdomen (may indicate urinary retention) or unilateral mass (occasionally seen in adult, indicating enlargement of one or both kidneys from large tumor or polycystic kidney)

Weight: Weight gain secondary to edema; weight loss and muscle wasting in kidney failure

General state of health: Fatigue, lethargy, and diminished alertness

Palpation. The kidneys are posterior organs protected by the abdominal organs, the ribs, and the heavy back muscles. A landmark useful in locating the kidneys is the **costovertebral angle (CVA)** formed by the rib cage and the vertebral column. The normal-sized left kidney is rarely palpable because the spleen lies directly on top of it. Occasionally the lower pole of the right kidney is palpable.

To palpate the right kidney, place your left (anterior) hand behind and support the patient's right side between the rib cage and the iliac crest (Fig. 45-6). Elevate the right flank with the left hand. Use your right hand to palpate deeply for the right kidney. The lower pole of the right kidney may be felt as a smooth, rounded mass that descends on inspiration. If the kidney is palpable, note its size, contour, and tenderness. Kidney enlargement is suggestive of neoplasm or other serious renal pathologic conditions.

The urinary bladder is normally not palpable unless it is distended with urine. If the bladder is full, it may be felt as a smooth, round, firm organ and is sensitive to palpation.

Percussion. Tenderness in the flank area may be detected by fist percussion *(kidney punch).* This technique is performed by

FIG. 45-6 Palpating the right kidney.

striking the fist of one hand against the dorsal surface of the other hand, which is placed flat along the posterior CVA margin (Fig. 45-7). Normally a firm blow in the flank area should not elicit pain. If CVA tenderness and pain are present, it may indicate a kidney infection or polycystic kidney disease.

A bladder is not normally percussible until it contains 150 mL of urine. If the bladder is full, dullness is heard above the symphysis pubis. A distended bladder may be percussed as high as the umbilicus.

Auscultation. The bell of the stethoscope may be used to auscultate over both CVAs and in the upper abdominal quadrants. With this technique, auscultate the abdominal aorta and renal arteries for a *bruit* (an abnormal murmur), which indicates impaired blood flow to the kidneys. Use the diaphragm of the stethoscope to auscultate the bowels, since they may also affect the urinary system.

Table 45-6 shows how to record the normal physical assessment findings of the urinary system. Table 45-7 presents assessment abnormalities of the urinary system. Assessment findings may vary in the older adult. Table 45-2 shows the age-related changes in the urinary system and differences in assessment findings. Use a *focused assessment* to evaluate the status of previously identified urinary system problems and to monitor for signs of new problems (see Table 3-6). A focused assessment of the urinary system is presented in the box on p. 1051.

FIG. 45-7 Indirect fist percussion of the costovertebral angle (CVA). To assess the kidney, place one hand over the twelfth rib at the CVA on the back. Thump that hand with the ulnar edge of the other fist. (From Jarvis C: *Physical examination and health assessment,* ed 6, St Louis, 2012, Saunders.)

TABLE 45-6 NORMAL PHYSICAL ASSESSMENT OF URINARY SYSTEM

- No costovertebral angle tenderness
- Nonpalpable kidney and bladder
- No palpable masses

DIAGNOSTIC STUDIES OF URINARY SYSTEM

Numerous diagnostic studies are available to locate and assess problems of the urinary system. Tables 45-8 and 45-9 describe the most common studies, and select studies are described in more detail in the following text.

The accuracy of these diagnostic studies is influenced by (1) adherence to the proper procedures; and (2) the patient's cooperation in terms of fluid restriction, urine specimen collection, study preparations procedures, ability to remain positioned on examination table, or following of other instructions.

Many radiologic studies require the use of a bowel preparation the evening before the study to clear the lower GI tract of feces and flatus. Because the kidneys lie in a retroperitoneal location, the contents of the colon may obstruct visualization of the urinary tract. If the bowel preparation fails to adequately evacuate the lower tract, the study may be unsuccessful and have to be rescheduled. Commonly used bowel preparations include enemas, castor oil, magnesium citrate, and bisacodyl (Dulcolax) tablets or suppositories. Some bowel preparations, such as magnesium citrate and Fleet enema, are contraindicated because magnesium cannot be excreted by the kidneys in patients with kidney failure (see Chapter 47).

When a patient has had diagnostic studies on consecutive days, it is important to prevent dehydration. Often the patient takes nothing by mouth (NPO) after midnight, spends an

Text continued on p. 1061

CASE STUDY—cont'd

Objective Data: Physical Examination

iStockphoto/Thinkstock

A focused assessment of A.K. reveals the following:

A.K. is lying on the ED stretcher with his knees bent and drawn to his abdominal area. He appears restless and keeps moving from back to side in an effort to reduce his discomfort. Vital signs as follows: BP 156/70, apical pulse 108, respiratory rate 24, temperature 37.4° C, O_2 saturation 96% on room air. Awake, alert, and oriented × 3. Lungs clear to auscultation. Apical pulse regular. Abdomen nondistended with + bowel sounds in all 4 quadrants. No rebound tenderness. Positive costovertebral tenderness. Voiding small amounts of dark, smoky urine.

As you continue to read this chapter, consider diagnostic studies you would anticipate being performed for A.K.

TABLE 45-7 ASSESSMENT ABNORMALITIES

Urinary System

Finding	Description	Possible Etiology and Significance
Anuria	Technically no urination (24-hr urine output <100 mL)	Acute kidney injury, end-stage kidney disease, bilateral ureteral obstruction
Burning on urination	Stinging pain in urethral area	Urethral irritation, urinary tract infection
Dysuria	Painful or difficult urination	Sign of urinary tract infection, interstitial cystitis, and wide variety of pathologic conditions
Enuresis	Involuntary nocturnal urination	Symptomatic of lower urinary tract disorder
Frequency	Increased incidence of urination	Acutely inflamed bladder, retention with overflow, excess fluid intake, intake of bladder irritants
	Blood in the urine	Cancer of genitourinary tract, blood dyscrasias, kidney disease, urinary tract infection, stones in kidney or ureter, medications (anticoagulants)
Hesitancy	Delay or difficulty in initiating urination	Partial urethral obstruction, benign prostatic hyperplasia
Incontinence	Inability to voluntarily control discharge of urine	Neurogenic bladder, bladder infection, injury to external sphincter
Nocturia	Frequency of urination at night	Kidney disease with impaired concentrating ability, bladder obstruction, heart failure, diabetes mellitus, finding after renal transplant, excessive evening and nighttime fluid intake
Oliguria	Diminished amount of urine in a given time (24-hr urine output of 100-400 mL)	Severe dehydration, shock, transfusion reaction, kidney disease, end-stage kidney disease
Pain	Suprapubic pain (related to bladder), urethral pain (irritation of bladder neck), flank (CVA) pain	Infection, urinary retention, foreign body in urinary tract, urethritis, pyelonephritis, renal colic or stones
Pneumaturia	Passage of urine containing gas	Fistula connections between bowel and bladder, gas-forming urinary tract infections
Polyuria	Large volume of urine in a given time	Diabetes mellitus, diabetes insipidus, chronic kidney disease, diuretics, excess fluid intake, obstructive sleep apnea
Retention	Inability to urinate even though bladder contains excessive amount of urine	Finding after pelvic surgery, childbirth, catheter removal, anesthesia; urethral stricture or obstruction; neurogenic bladder
Stress incontinence	Involuntary urination with increased pressure (sneezing or coughing)	Weakness of sphincter control, lack of estrogen, urinary retention

CVA, Costovertebral angle.

TABLE 45-8 DIAGNOSTIC STUDIES

Urinary System

Study	Description and Purpose	Nursing Responsibility
Urine Studies		
Urinalysis	General examination of urine to establish baseline information or provide data to establish a tentative diagnosis and determine whether further studies are needed (see Table 45-9).	Try to obtain first urinated morning specimen. Ensure specimen is examined within 1 hr of urinating. Before collecting, wash perineal area (if soiled with menses or fecal material).
Creatinine clearance	Creatinine is a waste product of protein breakdown (primarily body muscle mass). Clearance of creatinine by kidney approximates the GFR. Creatinine clearance is calculated as follows: $\text{Creatinine clearance} = \frac{\text{Urine creatinine (mg/dL)} \times \text{Urine volume (mL/min)}}{\text{Serum creatinine (mg/dL)}}$ *Reference interval:* 70-135 mL/min/1.73 m^2 (corrected for body surface area).	Collect 24-hr urine specimen. Discard first urination when test is started. Save urine from all subsequent urinations for 24 hr. Instruct patient to urinate at end of 24 hr and add specimen to collection. Ensure that serum creatinine is determined during 24-hr period.
Composite urine collection	Measures specific components, such as electrolytes, glucose, protein, 17-ketosteroids, catecholamines, creatinine, and minerals. Composite urine specimens are collected over a period ranging from 2 to 24 hr.	Instruct the patient to urinate and discard this first urine specimen. Note this time as the start of the test. Save all urine from subsequent urinations in a container for designated period. At end of period, ask patient to urinate, and this urine is added to container. Remind patient to save all urine during study period. Specimens may have to be refrigerated, or preservatives may have to be added to container used for collecting urine.

GFR, Glomerular filtration rate.

TABLE 45-8 DIAGNOSTIC STUDIES—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Urine culture ("clean catch," "midstream")	Confirms suspected urinary tract infection and identifies causative organisms. *Normally,* bladder is sterile, but urethra contains bacteria and a few WBCs. *Reference interval:* If properly collected, stored, and handled: $<10^3$ organisms/mL usually indicates no infection. 10^3-10^5/mL is usually not diagnostic and test may have to be repeated. $>10^5$/mL indicates infection.	Use sterile container for collection of urine. Touch only outside of container. For women, separate labia with one hand and clean meatus with other hand, using at least three sponges (saturated with cleansing solution) in a front-to-back motion. For men, retract foreskin (if present) and cleanse glans with at least three cleansing sponges. After cleaning, instruct patient to start urinating and then continue voiding in sterile container. (The initial voided urine flushes out most contaminants in the urethra and perineal area.) Catheterization may be needed if patient is unable to cooperate with procedure.
Concentration test	Evaluates renal concentration ability. Measured by specific gravity readings. *Reference interval:* 1.003-1.030.	Instruct patient to fast after given time in evening (in usual procedure). Collect three urine specimens at hourly intervals in morning.
Residual urine	Determines amount of urine left in bladder after urinating. Finding may be abnormal in problems with bladder innervation, sphincter impairment, BPH, or urethral strictures. *Reference interval:* ≤50 mL urine (increases with age).	Immediately after patient urinates, catheterize patient or use bladder ultrasound equipment. If a large amount of residual urine is obtained, health care provider may want catheter left in bladder.
Protein determination		
• Dipstick (Albustix, Combistix)	Test detects protein (primarily albumin) in urine. *Reference interval:* 0-trace.	Dip end of stick in urine and read result by comparison with color chart on label as directed. Grading is from 0 to 4+. Interpret with caution. Positive result may not indicate significant proteinuria. Some medications may give false-positive readings.
• Quantitative protein test	A 24-hr collection gives a more accurate indication of amount of protein in urine. Persistent proteinuria usually indicates glomerular kidney disease. *Reference interval:* <150 mg/24 hr (mainly albumin).	Perform 24-hr urine collection as above.
Urine cytologic study	Identifies abnormal cellular structures that occur with bladder cancer. Also used to follow the progress of bladder cancer after treatment.	Obtain specimens by voiding, catheterization, or bladder irrigation. Do not use morning's first voided specimen because epithelial cells may change in appearance in urine held in bladder overnight. As with urinalysis, the specimen should be fresh or brought to laboratory within the hour. An alcohol-based fixative is then added to preserve the cellular structure.
Blood Studies		
Blood urea nitrogen (BUN)	Used to detect renal problems. Concentration of urea in blood is regulated by rate at which kidney excretes urea. *Reference interval:* 6-20 mg/dL (2.1-7.1 mmol/L).	When interpreting BUN, be aware that nonrenal factors may cause increase (e.g., rapid cell destruction from infections, fever, GI bleeding, trauma, athletic activity and excessive muscle breakdown, corticosteroid therapy).
Creatinine	More reliable than BUN as a determinant of renal function. Creatinine is end product of muscle and protein metabolism and is released at a constant rate. *Reference interval:* 0.6-1.3 mg/dL (53-115 μmol/L).	Explain test and watch for postpuncture bleeding.
BUN/creatinine ratio	An increased ratio may be due to conditions that decrease blood flow to kidneys (e.g., heart failure, dehydration), GI bleeding, or increased dietary protein. A decreased ratio may occur with liver disease (due to decreased urea formation) and malnutrition. *Reference interval:* 12:1 to 20:1.	
Uric acid	Used as screening test primarily for disorders of purine metabolism but can also indicate kidney disease. Values depend on renal function, rate of purine metabolism, and dietary intake of food rich in purines. *Female:* 2.3-6.6 mg/dL (137-393 μmol/L). *Male:* 4.4-7.6 mg/dL (262-452 μmol/L).	Explain test and watch for postpuncture bleeding.
Sodium	Main extracellular electrolyte determining blood volume. Usually values stay within normal range until late stages of renal failure. *Reference interval:* 135-145 mEq/L (135-145 mmol/L).	Explain test and watch for postpuncture bleeding.

BPH, Benign prostatic hyperplasia.

Continued

TABLE 45-8 DIAGNOSTIC STUDIES—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Blood Studies—cont'd		
Potassium	Kidneys are responsible for excreting majority of body's potassium. In kidney disease, K^+ determinations are critical because K^+ is one of the first electrolytes to become abnormal. Elevated K^+ levels >6 mEq/L can lead to muscle weakness and cardiac dysrhythmias. *Reference interval:* 3.5-5.0 mEq/L (3.5-5.0 mmol/L).	Explain test and watch for postpuncture bleeding.
Calcium (total)	Main mineral in bone and aids in muscle contraction, neurotransmission, and clotting. In kidney disease, decreased reabsorption of Ca^{2+} leads to renal osteodystrophy. *Reference interval:* 8.6-10.2 mg/dL (2.15-2.55 mmol/L).	Explain test and watch for postpuncture bleeding.
Phosphorus	Phosphorus balance is inversely related to Ca^{2+} balance. In kidney disease, phosphorus levels are elevated because the kidney is the primary excretory organ. *Reference interval:* 2.4-4.4 mg/dL (0.78-1.42 mmol/L).	Explain test and watch for postpuncture bleeding.
Bicarbonate	Most patients in renal failure have metabolic acidosis and low serum HCO_3^- levels. *Reference interval:* 22-26 mEq/L (22-26 mmol/L).	Explain test and watch for postpuncture bleeding.
Radiologic Procedures		
Kidneys, ureters, bladder (KUB)	X-ray examination of abdomen and pelvis delineates size, shape, and position of kidneys. Radiopaque stones and foreign bodies can be seen.	Perform bowel preparation (if ordered).
Intravenous pyelogram (IVP)	Visualizes urinary tract after IV injection of contrast media. Presence, position, size, and shape of kidneys, ureters, and bladder can be evaluated. Cysts, tumors, lesions, and obstructions cause a distortion in normal appearance of these structures. Patient with significantly decreased renal function should not have IVP because contrast media can be nephrotoxic and worsen renal function.*	Evening before procedure, give cathartic or enema to empty colon of feces and gas. Before procedure, assess patient for iodine sensitivity to avoid anaphylactic reaction. Inform patient that procedure involves lying on table and having serial x-rays taken. Advise patient that during injection of contrast material, warmth, a flushed face, and a salty taste may be experienced. After procedure, force fluids (if permitted) to flush out contrast media.
Renal arteriogram (angiogram)	Visualizes renal blood vessels. Can assist in diagnosing renal artery stenosis (Fig. 45-8), additional or missing renal blood vessels, and renovascular hypertension. Can assist in differentiating between a renal cyst and a renal tumor. Also included in workup of a potential renal transplant donor. A catheter is inserted into the femoral artery and passed up the aorta to the level of the renal arteries (Fig. 45-9). Contrast media is injected to outline the renal blood supply.*	*Before procedure:* Prepare patient the prior evening by giving cathartic or enema. Before injection of contrast material, assess for iodine sensitivity. The patient may experience a transient warm feeling along the course of the blood vessel when contrast media is injected. *After procedure:* Place a pressure dressing over femoral artery injection site. Observe site for bleeding. Have patient maintain bed rest with affected leg straight. Take peripheral pulses in the involved leg every 30-60 min to detect occlusion of blood flow caused by a thrombus. Observe for complications, including thrombus, embolus, local inflammation, hematoma.

**N*-acetylcysteine (Mucomyst), a renal vasodilator and antioxidant, is sometimes administered to reduce the incidence of contrast-induced nephropathy; can be given by oral or IV route.

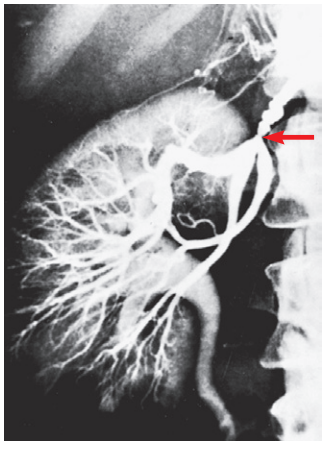

FIG. 45-8 Renal arteriogram showing stenosis of the right renal artery *(arrow)*.

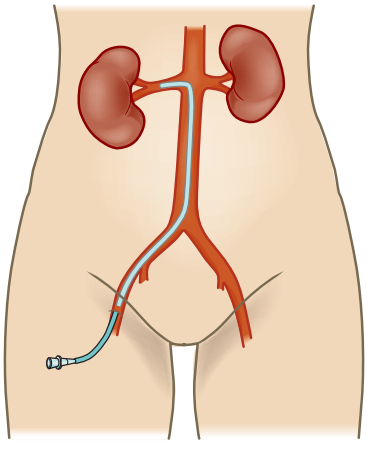

FIG. 45-9 Catheter insertion for a renal arteriogram.

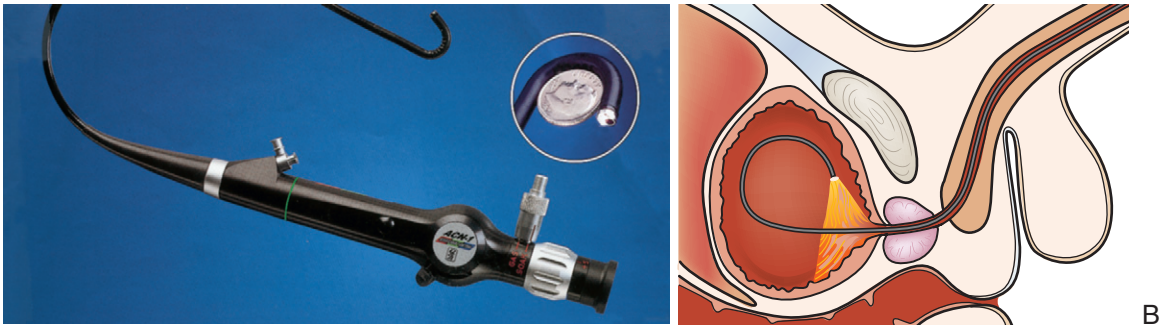
TABLE 45-8 DIAGNOSTIC STUDIES—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Antegrade pyelogram (nephrostogram)	Evaluates upper urinary tract when patient has allergy to contrast media, decreased renal function, or abnormalities that prevent passage of a ureteral catheter. Contrast media may be injected percutaneously into renal pelvis or via a nephrostomy tube that is already in place when determining tube function or ureteral integrity after trauma or surgery.*	Explain procedure and prepare patient as for IVP. Watch for signs of complications (e.g., hematuria, infection, hematoma).
Retrograde pyelogram	X-ray of urinary tract taken after injection of contrast material into kidneys. It may be done if an IVP does not visualize the urinary tract or if patient is allergic to contrast media or has decreased renal function. A cystoscope is inserted and ureteral catheters are inserted through it into renal pelvis. Contrast media is injected through catheters.*	Prepare patient as for IVP. Inform patient that pain may be experienced from distention of pelvis and discomfort from cystoscope. Inform patient that anesthesia may be given for procedure. Complications are similar to those for cystoscopy (see cystoscopy later in table).
Renal ultrasound	Used to detect renal or perirenal masses, differential diagnosis of renal cysts, solid masses, and identification of obstructions. Small external ultrasound probe is placed on patient's skin. Conductive gel is applied to skin. Noninvasive procedure involves passing sound waves into body structures and recording images as they are reflected back. Computer interprets tissue density based on sound waves and displays it in picture form. It can be used safely in patients with renal failure.	Explain procedure to patient. Because radiation exposure is avoided, a number of images can be obtained and repeat studies can be done over a brief period. Images can be obtained from both prone and supine positions. A bowel preparation is not required.
Computed tomography (CT) scan (CT urogram)	Provides excellent visualization of kidneys. Kidney size can be evaluated. Tumors, abscesses, suprarenal masses (e.g., adrenal tumors, pheochromocytomas), and obstructions can be detected. Advantage of CT over ultrasound is its ability to distinguish subtle differences in density. Use of IV-administered contrast media during CT accentuates density of renal tissue and helps differentiate masses.*	Explain procedure to patient. Ask patient about iodine sensitivity. Instruct the patient to lie still during the procedure while the machine takes precise transaxial images. Sedation may be required if patient is unable to cooperate.
Magnetic resonance imaging (MRI)	Useful for visualization of kidneys. Not proven useful for detecting urinary calculi or calcified tumors. Computer-generated films rely on radiofrequency waves and alteration in magnetic field.	Explain procedure to patient. Have patient remove all metal objects. Patients with a history of claustrophobia may need to be sedated. Contraindications: presence of implanted magnetic clips or prosthesis and pacemakers.
Magnetic resonance angiography	Allows visualization of renal vasculature. Gadolinium-enhanced studies allow visualization of the renal artery.	Same as above. Does not require femoral artery puncture.
Cystogram	Visualizes bladder and evaluates vesicoureteral reflux. Also evaluates patients with neurogenic bladder and recurrent urinary tract infections. Can also delineate abnormalities of the bladder (e.g., diverticula, calculi, tumors). Contrast media is instilled into bladder via cystoscope or catheter.	Explain procedure to patient. If done via cystoscope, follow nursing care related to cystoscopy.
Urethrogram	Similar to a cystogram. Contrast media is injected retrograde into the urethra to identify strictures, diverticula, or other urethral pathologic conditions. When urethral trauma is suspected, a urethrogram is done before catheterization.	Explain procedure to patient.
Voiding cystourethrogram (VCUG)	Voiding study of the bladder opening (bladder neck) and urethra. The bladder is filled with contrast media. Fluoroscopic films are taken to visualize the bladder and urethra. After urination, another film is taken to assess for residual urine. Can detect abnormalities of the lower urinary tract, urethral stenosis, bladder neck obstruction, and prostatic enlargement.	Explain procedure to patient.
Loopogram	Detects obstructions, anastomotic leaks, stones, reflux, and other uropathologic features when patient has a urinary pouch or ileal conduit. Because urinary diversions are created with bowel, there is risk of absorption of contrast media.	Explain procedure to patient. Closely monitor patient for reactions to the contrast media.



*_N_-acetylcysteine (Mucomyst), a renal vasodilator and antioxidant, is sometimes administered to reduce the incidence of contrast-induced nephropathy; can be given by oral or IV route.

Continued

TABLE 45-8 DIAGNOSTIC STUDIES—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Endoscopy		
Cystoscopy	Inspects interior of bladder with a tubular lighted scope (cystoscope) (Fig. 45-10). Can be used to insert ureteral catheters, remove calculi, obtain biopsy specimens of bladder lesions, and treat bleeding lesions. Lithotomy position is used. Procedure may be done using local or general anesthesia, depending on patient's needs and condition. Complications include urinary retention, urinary tract hemorrhage, bladder infection, and perforation of the bladder.	*Before procedure:* Force fluids or give IV fluids if general anesthesia is to be used. Ensure consent form is signed. Explain procedure to patient. Give preoperative medication. *After procedure:* Explain that burning on urination, pink-tinged urine, and urinary frequency are expected effects. Observe for bright red bleeding, which is not normal. Do not let patient walk alone immediately after procedure because orthostatic hypotension may occur. Offer warm sitz baths, heat, mild analgesics to relieve discomfort.
Urodynamic Studies		
Urine flow study (uroflow)	Measures urine volume in a single voiding expelled in a period of time. Used to (1) assess the degree of outflow obstruction caused by such conditions as BPH or stricture, (2) assess bladder or sphincter dysfunction effects on voiding, and (3) evaluate effects of treatment for lower urinary tract problems. Graphic displays can illustrate straining and intermittent flow patterns or other abnormal voiding disorders. *Normal maximum flow rate:* men: 20-25 mL/sec; women: 25-30 mL/sec. Volume voided and the patient's age can affect the flow rate.	Explain procedure to patient. Ask the patient to start the test with a comfortably full bladder, urinate into a special container, and try to empty completely. Measure residual urine volume immediately after a urinary flow study because this will help identify the degree of chronic urinary retention that is often associated with abnormal flow patterns.
Cystometrogram	Evaluates bladder's capacity to contract and expel urine. Involves insertion of catheter and instillation of water or saline solution into bladder. Measurements of pressure exerted against bladder wall are recorded. If abdominal pressure is measured, a second tube is inserted into the rectum or vagina. This tube is attached to a small fluid-filled balloon to allow pressure recording.	Explain procedure to patient. During the infusion, ask patient about sensations of bladder filling, usually including the first desire (urge) to urinate, a strong desire to urinate, and perception of bladder fullness. Observe patient for manifestations of urinary tract infection after procedure.
Sphincter electromyography (EMG)	Recording of electrical activity created when nervous system stimulates muscle tissue. By placing needles, percutaneous wires, or patches near the urethra, the clinician can assess the pelvic floor muscle activity. During the cystometrogram, sphincter EMG is used to identify voluntary pelvic floor muscle contractions and the response of these muscles to bladder filling, coughing, and other provocative maneuvers.	Explain procedure to patient.
Voiding pressure flow study	Combines a urinary flow rate, cystometric pressures (intravesical, abdominal, and detrusor pressures), and a sphincter EMG for detailed evaluation of micturition. It is completed by assisting the patient to a specialized toilet to urinate while the various pressure tubes and EMG apparatus remain in place.	Explain procedure to patient.
Videourodynamics	Combination of cystometrogram, sphincter EMG, and/or urinary flow study with anatomic imaging of the lower urinary tract, typically via fluoroscopy. Used in selected cases to identify an obstructive lesion and characterize anatomic changes in the bladder and lower urinary tract.	Explain procedure to patient.

A B

FIG. 45-10 Cystoscopic examination of the bladder in a man. **A,** Flexible cystonephroscope. **B,** Scope inserted into bladder.

TABLE 45-8 DIAGNOSTIC STUDIES—cont'd

Urinary System

Study	Description and Purpose	Nursing Responsibility
Radionuclide cystography (RNC)	Detects and grades vesicoureteral reflux. Similar to VCUG with a small dose of radioisotope tracer instilled into the bladder via urethral catheter. More sensitive than VCUG, and radiation dose is 1/1000 that of the VCUG.	Explain procedure to patient as in VCUG.
Whitaker study	Measures the pressure differential between the renal pelvis and the bladder. Ureteral obstruction can be assessed. Percutaneous access is gained to the renal pelvis by placing a catheter in the renal pelvis. A catheter is also placed in the bladder. Fluid is perfused through the percutaneous tube or needle at a rate of 10 mL/min. Pressure data are then collected. Pressure measurements are combined with fluoroscopic imaging to identify the level of obstruction.	Explain procedure to patient.
Renal Scan	Evaluates anatomic structures, perfusion, and function of kidneys. Radioactive isotopes are injected IV. Radiation detector probes are placed over kidney, and scintillation counter monitors radioactive material in kidney. Radioisotope distribution in kidney is scanned and mapped. Shows location, size, and shape of kidney and, in general, assesses blood flow, glomerular filtration, tubular function, and urinary excretion. Abscesses, cysts, and tumors may appear as cold spots because of nonfunctioning tissue. Also monitors function of a transplanted kidney.	Requires no dietary or activity restriction. Inform patient that no pain or discomfort should be felt during test.
Renal Biopsy	Obtains renal tissue for examination to determine type of kidney disease or to follow progress of kidney disease. Technique is usually done as a skin (percutaneous) biopsy through needle insertion into lower lobe of kidney. Can be performed with CT or ultrasound guidance. Absolute contraindications are bleeding disorders, single kidney, and uncontrolled hypertension. Relative contraindications include suspected renal infection, hydronephrosis, and possible vascular lesions.	Type and crossmatch patient for blood. Ensure consent form is signed. *Before procedure:* Ascertain coagulation status through patient history, medication history, CBC, hematocrit, prothrombin time, and bleeding and clotting time. Patient should not be taking aspirin or warfarin (Coumadin). *After procedure:* Apply pressure dressing and keep patient on affected side for 30-60 min. Bed rest for 24 hr. Vital signs every 5-10 min, first hour. Assess for flank pain, hypotension, decreasing hematocrit, ↑ temperature, chills, urinary frequency, dysuria, and serial urine specimens (gross or microscopic hematuria). Urine dipstick can be used to test for bleeding in urine. Inspect biopsy site for bleeding. Instruct patient to avoid lifting heavy objects for 5-7 days and to not take anticoagulant drugs until allowed by health care provider.

extended time in the x-ray department, is too tired to eat, sleeps the rest of the day, and is NPO after midnight again because of studies scheduled for the next day. Severe dehydration, especially in a diabetic, debilitated, or older patient, may lead to acute kidney injury. When a patient is scheduled for diagnostic studies, ensure that the patient is properly hydrated and given adequate nourishment between studies. Also check with the health care provider regarding insulin dosage for diabetic patients who are placed on NPO status.

Urine Studies

Urinalysis. *Urinalysis* (see Tables 45-8 and 45-9) is one of the first studies done to evaluate disorders of the urinary tract. Results from the urinalysis may indicate possible abnormalities, suggest the need for further studies, or provide evidence of progression in a previously diagnosed disorder.

Although a specimen may be collected at any time of the day for a routine urinalysis, it is best to obtain the first specimen urinated in the morning. This concentrated specimen is more likely to contain abnormal constituents if they are present in the urine. The specimen should be examined within 1 hour of urinating. Otherwise, bacteria multiply rapidly, RBCs hemolyze, *casts* (molds of renal tubules) disintegrate, and the urine becomes alkaline as a result of urea-splitting bacteria. If it is not possible to send the specimen to the laboratory immediately, refrigerate it. However, to obtain the best results, coordinate specimen collection with routine laboratory hours.

Creatinine Clearance. A common test used to analyze urinary system disorders is creatinine clearance. Creatinine is a waste product produced by muscle breakdown. Urinary excretion of creatinine is a measure of the amount of active muscle tissue in the body, not of body weight. Therefore individuals with larger muscle mass have higher values.[4] Because almost all creatinine in the blood is normally excreted by the kidneys, creatinine clearance is the most accurate indicator of renal function. The result of a creatinine clearance test closely approxi-

TABLE 45-9 DIAGNOSTIC STUDIES

Urinalysis

Test	Normal	Abnormal Finding	Possible Etiology and Significance
Color	Amber yellow	Dark, smoky color	Hematuria.
		Yellow-brown to olive green	Excessive bilirubin.
		Orange-red or orange-brown	phenazopyridine (Pyridium).
		Cloudiness of freshly voided urine	Infection.
		Colorless urine	Excessive fluid intake, kidney disease, or diabetes insipidus.
Odor	Aromatic	Ammonia-like odor	Urine allowed to stand.
		Unpleasant odor	Urinary tract infection.
Protein	Random protein (dipstick): 0-trace	Persistent proteinuria	Characteristic of acute and chronic kidney disease, especially involving glomeruli. Heart failure.
	24-hr protein (quantitative): <150 mg/day		In absence of disease: high-protein diet, strenuous exercise, dehydration, fever, emotional stress, contamination by vaginal secretions.
Glucose	None	Glycosuria	Diabetes mellitus, low renal threshold for glucose reabsorption (if blood glucose level is normal). Pituitary disorders.
Ketones	None	Present	Altered carbohydrate and fat metabolism in diabetes mellitus and starvation; dehydration, vomiting, severe diarrhea.
Bilirubin	None	Present	Liver disorders. May appear before jaundice is visible (see Chapter 44).
Specific gravity	1.003-1.030	Low	Dilute urine, excessive diuresis, diabetes insipidus.
	Maximum concentrating ability of kidney in morning urine (1.025-1.030)	High	Dehydration, albuminuria, glycosuria.
		Fixed at about 1.010	Renal inability to concentrate urine; end-stage kidney disease.
Osmolality	300-1300 mOsm/kg (300-1300 mmol/kg)	<300 mOsm/kg	Tubular dysfunction. Kidney lost ability to concentrate or dilute urine (not part of routine urinalysis).
		>1300 mOsm/kg	
pH	4.0-8.0 (average, 6.0)	>8.0	Urinary tract infection. Urine allowed to stand at room temperature (bacteria decompose urea to ammonia).
		<4.0	Respiratory or metabolic acidosis.
RBCs	0-4/hpf	>4/hpf	Calculi, cystitis, neoplasm, glomerulonephritis, tuberculosis, kidney biopsy, trauma.
WBCs	0-5/hpf	>5/hpf	Urinary tract infection or inflammation.
Casts	None	Present	Molds of the renal tubules that may contain protein, WBCs, RBCs, or bacteria. Noncellular casts (hyaline in appearance) occasionally found in normal urine.
	Occasional hyaline		
Culture for organisms	No organisms in bladder	Bacteria counts >10^5/mL	Urinary tract infection; most common organisms are *Escherichia coli,* enterococci, *Klebsiella, Proteus,* and streptococci.
	<10^4 organisms/mL result of normal urethral flora		

hpf, High-powered field.

mates that of the GFR. A blood specimen for serum creatinine determination should be obtained during the period of urine collection.

Creatinine levels remain remarkably constant for each person because they are not significantly affected by protein ingestion, muscular exercise, water intake, or rate of urine production. Normal creatinine clearance values range from 70 to 135 mL/min (see Table 45-8). After age 40, the creatinine clearance rate decreases at a rate of about 1 mL/min/yr.

Urodynamic Studies

Urodynamic studies measure urinary tract function. Urodynamic tests study the storage of urine within the bladder and the flow of urine through the urinary tract to the outside of the body.[5-7] A combination of techniques may be used for a detailed assessment of urinary function (see Table 45-8).

CASE STUDY—cont'd

Objective Data: Diagnostic Studies

iStockphoto/Thinkstock

The health care provider orders the following initial diagnostic studies for A.K.:

- CBC, basic metabolic panel (electrolytes, BUN, creatinine)
- Urinalysis, culture if indicated
- Renal ultrasound

Although A.K.'s laboratory results are all within normal limits, his renal ultrasound identifies calculi in the left ureter. There is no hydronephrosis at present. The health care provider prescribes parenteral opioids for pain management and admits A.K. to a medical unit for further observation.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. A renal stone in the pelvis of the kidney will alter the function of the kidney by interfering with
   a. the structural support of the kidney.
   b. regulation of the concentration of urine.
   c. the entry and exit of blood vessels at the kidney.
   d. collection and drainage of urine from the kidney.
2. A patient with kidney disease has oliguria and a creatinine clearance of 40 mL/min. These findings most directly reflect abnormal function of
   a. tubular secretion.
   b. glomerular filtration.
   c. capillary permeability.
   d. concentration of filtrate.
3. The nurse identifies a risk for urinary calculi in a patient who relates a past health history that includes
   a. hyperaldosteronism.
   b. serotonin deficiency.
   c. adrenal insufficiency.
   d. hyperparathyroidism.
4. Diminished ability to concentrate urine, associated with aging of the urinary system, is attributed to
   a. a decrease in bladder sensory receptors.
   b. a decrease in the number of functioning nephrons.
   c. decreased function of the loop of Henle and tubules.
   d. thickening of the basement membrane of Bowman's capsule.
5. During physical assessment of the urinary system, the nurse
   a. palpates an empty bladder as a small nodule.
   b. auscultates over each CVA to detect impaired renal blood flow.
   c. finds a dull percussion sound when 100 mL of urine is present in the bladder.
   d. palpates above the symphysis pubis to determine the level of urine in the bladder.
6. Normal findings expected by the nurse on physical assessment of the urinary system include *(select all that apply)*
   a. nonpalpable left kidney.
   b. auscultation of renal artery bruit.
   c. CVA tenderness elicited by a kidney punch.
   d. no CVA tenderness elicited by a kidney punch.
   e. palpable bladder to the level of the pubic symphysis.
7. A diagnostic study that indicates renal blood flow, glomerular filtration, tubular function, and excretion is a(n)
   a. IVP.
   b. VCUG.
   c. renal scan.
   d. loopogram.
8. On reading the urinalysis results of a dehydrated patient, the nurse would expect to find
   a. a pH of 8.4.
   b. RBCs of 4/hpf.
   c. color: yellow, cloudy.
   d. specific gravity of 1.035.

1. d, 2. b, 3. d, 4. c, 5. b, 6. a, d, 7. c, 8. d

LEARNING OUTCOMES

1. Differentiate the pathophysiology, clinical manifestations, collaborative care, and drug therapy of cystitis, urethritis, and pyelonephritis.
2. Explain the nursing management of urinary tract infections.
3. Describe the immunologic mechanisms involved in glomerulonephritis.
4. Differentiate the clinical manifestations and nursing and collaborative management of acute poststreptococcal glomerulonephritis, Goodpasture syndrome, and chronic glomerulonephritis.
5. Describe the common causes, clinical manifestations, collaborative care, and nursing management of nephrotic syndrome.
6. Compare and contrast the etiology, clinical manifestations, collaborative care, and nursing management of various types of urinary calculi.
7. Differentiate the common causes and management of renal trauma, renal vascular problems, and hereditary kidney diseases.
8. Describe the clinical manifestations and nursing and collaborative management of kidney cancer and bladder cancer.
9. Describe the common causes and management of urinary incontinence and urinary retention.
10. Differentiate among urethral, ureteral, suprapubic, and nephrostomy catheters with regard to indications for use and nursing responsibilities.
11. Explain the nursing management of the patient undergoing nephrectomy or urinary diversion surgery.

Renal and urologic disorders encompass a wide spectrum of problems. The diverse causes of these disorders may involve infectious, immunologic, obstructive, metabolic, collagen-vascular, traumatic, congenital, neoplastic, and neurologic mechanisms. This chapter discusses specific disorders of the upper urinary tract (kidneys and ureter) and lower urinary tract (bladder and urethra). Acute kidney injury and chronic kidney disease are discussed in Chapter 47.

INFECTIOUS AND INFLAMMATORY DISORDERS OF URINARY SYSTEM

URINARY TRACT INFECTION

Urinary tract infections (UTIs) are the most common bacterial infection in women. During their lifetime, at least 20% of women develop at least one UTI.[1] More than 100,000 people

Reviewed by Barbara S. - *Candida albicans*†

*Causative microorganism for urinary tract infection (UTI) in 80% of cases without urinary tract structural abnormalities or calculi.
†Typically identified as the causative microorganism for UTI associated with the use of broad-spectrum antibiotic therapy or in patients with an indwelling catheter.

CULTURAL & ETHNIC HEALTH DISPARITIES

Urologic Disorders

- Urinary tract calculi are more common among whites than African Americans.
- Uric acid stones are more common in Jewish men.
- Bladder cancer has a higher incidence among white men than African American men.
- In all ethnic groups, bladder cancer affects men about three times more often than women.
- Urinary incontinence is underreported because culturally it is seen as a social hygiene problem causing patient embarrassment.

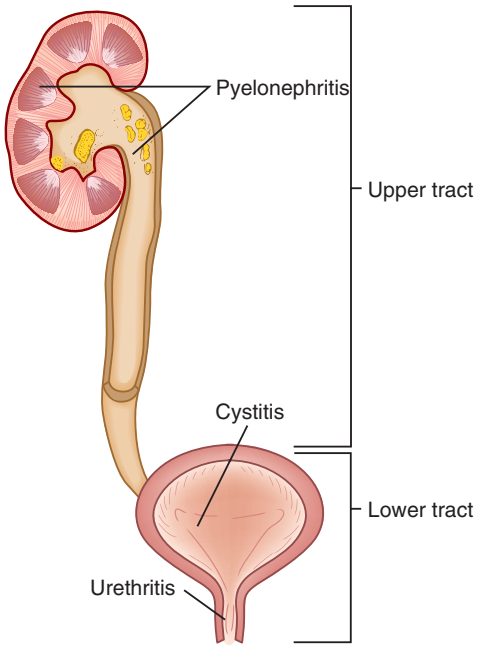

FIG. 46-1 Sites of infectious processes in the upper and lower urinary tracts.

are hospitalized annually for UTIs. More than 15% of patients who develop gram-negative bacteremia die, and one third of these cases are caused by bacterial infections originating in the urinary tract.[2]

Inflammation of the urinary tract may be caused by a variety of disorders, but bacterial infection is by far the most common. The bladder and its contents are free from bacteria in the majority of healthy persons. Nevertheless, a minority of otherwise healthy individuals have some bacteria colonizing the bladder. This condition is called *asymptomatic bacteriuria* and does not justify screening or treatment except in pregnant women.

Escherichia coli is the most common pathogen causing a UTI (Table 46-1) and is primarily seen in women. Bacterial counts of 10^5 colony-forming units per milliliter (CFU/mL) or higher typically indicate a clinically significant UTI. However, counts as low as 10^2 to 10^3 CFU/mL in a person with signs and symptoms are indicative of UTI.

Although fungal and parasitic infections may also cause UTIs, this is uncommon. UTIs from these causes are sometimes found in patients who are immunosuppressed, have diabetes mellitus, or have undergone multiple courses of antibiotic therapy. These types of UTIs may also be found in persons who live in or have traveled to certain developing countries.

Classification of Urinary Tract Infection

A UTI can be broadly classified as an upper or lower UTI according to its location within the urinary system (Fig. 46-1). Infection of the upper urinary tract (involving the renal parenchyma, pelvis, and ureters) typically causes fever, chills, and flank pain, whereas a UTI confined to the lower urinary tract does not usually have systemic manifestations. Specific terms are used to further delineate the location of a UTI. For example, **pyelonephritis** implies inflammation (usually caused by infection) of the renal parenchyma and collecting system, **cystitis** indicates inflammation of the bladder, and **urethritis** means inflammation of the urethra. **Urosepsis** is a UTI that has spread systemically and is a life-threatening condition requiring emergency treatment.

Classifying a UTI as complicated or uncomplicated is also useful. *Uncomplicated* UTIs occur in an otherwise normal urinary tract and usually involve only the bladder. *Complicated* UTIs include those infections with coexisting obstruction, stones, or catheters; diabetes or neurologic diseases; or pregnancy-induced changes. The term also applies to a recurrent infection. The individual with a complicated infection is at risk for pyelonephritis, urosepsis, and renal damage.

Etiology and Pathophysiology

The urinary tract above the urethra is normally sterile. Several mechanical and physiologic defense mechanisms assist in maintaining sterility and preventing UTIs. These defenses include normal voiding with complete emptying of the bladder, ureterovesical junction competence, and ureteral peristaltic activity that propels urine toward the bladder. Antibacterial characteristics of urine are maintained by an acidic pH (less than 6.0), high urea concentration, and abundant glycoproteins that interfere with the growth of bacteria. An alteration in any of these defense mechanisms increases the risk for a UTI (Table 46-2).

The organisms that usually cause UTIs are introduced via the ascending route from the urethra and originate in the perineum. Most infections are caused by gram-negative bacilli normally found in the gastrointestinal (GI) tract, although gram-positive organisms such as streptococci, enterococci, and *Staphylococcus saprophyticus* can also cause UTIs.

A common factor contributing to ascending infection is urologic instrumentation (e.g., catheterization, cystoscopic examinations).[3] Instrumentation allows bacteria that are normally present at the opening of the urethra to enter into the urethra or bladder. Sexual intercourse promotes "milking" of bacteria from the vagina and perineum and may cause minor urethral trauma that predisposes women to UTIs.

Rarely do UTIs result from a hematogenous route, where blood-borne bacteria secondarily invade the kidneys, ureters,

TABLE 46-2 RISK FACTORS FOR URINARY TRACT INFECTIONS

Factors Increasing Urinary Stasis
- Intrinsic obstruction (stone, tumor of urinary tract, urethral stricture, BPH)
- Extrinsic obstruction (tumor, fibrosis compressing urinary tract)
- Urinary retention (including neurogenic bladder and low bladder wall compliance)
- Renal impairment

Foreign Bodies
- Urinary tract calculi
- Catheters (indwelling, external condom catheter, ureteral stent, nephrostomy tube, intermittent catheterization)
- Urinary tract instrumentation (cystoscopy, urodynamics)

Anatomic Factors
- Congenital defects leading to obstruction or urinary stasis
- Fistula (abnormal opening) exposing urinary stream to skin, vagina, or fecal stream
- Shorter female urethra and colonization from normal vaginal flora
- Obesity

Factors Compromising Immune Response
- Aging
- Human immunodeficiency virus infection
- Diabetes mellitus

Functional Disorders
- Constipation
- Voiding dysfunction with detrusor sphincter dyssynergia

Other Factors
- Pregnancy
- Hypoestrogenic state (menopause)
- Multiple sex partners (women)
- Use of spermicidal agents or contraceptive diaphragm (women)
- Poor personal hygiene
- Habitual delay of urination ("nurse's bladder," "teacher's bladder")

TABLE 46-3 LOWER URINARY TRACT SYMPTOMS (LUTS)

Symptoms	Description
Emptying Symptoms	
Hesitancy	• Difficulty starting urine stream • Delay between initiation of urination (because of urethral sphincter relaxation) and beginning of flow of urine • Diminished urinary stream
Intermittency	• Interruption of urinary stream while voiding
Postvoid dribbling	• Urine loss after completion of voiding
Urinary retention or incomplete emptying	• Inability to empty urine from bladder • Caused by atonic bladder or obstruction of urethra • Can be acute or chronic
Dysuria	• Painful or difficult urination
Storage Symptoms	
Urinary frequency	• >8 times in 24-hr period • Often <200 mL each voiding
Urgency	• Sudden, strong, or intense desire to void immediately • Commonly accompanied by frequency
Incontinence	• Involuntary or accidental urine loss or leakage
Nocturia	• Awakened by urge to void 2 or more times during sleep • May be diurnal or nocturnal depending on sleep schedule
Nocturnal enuresis	• Adults: loss of urine during sleep

or bladder from elsewhere in the body. There must be prior injury to the urinary tract, such as obstruction of the ureter, damage caused by stones, or renal scars, for a kidney infection to occur from hematogenous transmission.

An important source of UTIs is health care–associated infections (HAIs), previously called *nosocomial* infections, which account for 31% of all HAIs.[2,4] The cause of HAIs is often *E. coli* and, less frequently, *Pseudomonas* organisms. Catheter-acquired urinary tract infections (CAUTIs) are the most common HAIs and are caused by development of bacterial biofilms that are found on the catheter's inner surface. Most often these infections are underrecognized and undertreated, leading to complications such as renal abscesses, epididymitis, periurethral gland infections, and bacteremia.

Clinical Manifestations

Lower urinary tract symptoms (LUTS) are experienced in patients who have UTIs of the upper urinary tract, as well as those confined to the lower tract. Symptoms are related to either bladder storage or bladder emptying. These symptoms are presented in Table 46-3.

These symptoms include dysuria, frequent urination (more than every 2 hours), urgency, and suprapubic discomfort or pressure. The urine may contain grossly visible blood (hematuria) or sediment, giving it a cloudy appearance. Flank pain, chills, and fever indicate an infection involving the upper urinary tract (pyelonephritis). People with significant bacteriuria may have no symptoms or may have nonspecific symptoms such as fatigue or anorexia.

Remember that these symptoms, considered characteristic of a UTI, are often absent in older adults. Older adults tend to experience nonlocalized abdominal discomfort rather than dysuria and suprapubic pain. In addition, they may have cognitive impairment or generalized clinical deterioration. Because older adults are less likely to experience a fever with a UTI, the value of body temperature as an indicator of a UTI is unreliable.

Multiple factors may produce LUTS similar to the symptoms of a UTI. For example, patients with bladder tumors or those receiving intravesical chemotherapy or pelvic radiation usually experience urinary frequency, urgency, and dysuria. Interstitial cystitis/painful bladder syndrome (discussed on p. 1071) also produces urinary symptoms that are similar to and sometimes confused with a UTI.

Diagnostic Studies

In a patient suspected of having a UTI, initially obtain a dipstick urinalysis to identify the presence of nitrites (indicating bacteriuria), white blood cells (WBCs), and leukocyte esterase (an enzyme present in WBCs indicating pyuria). These findings can be confirmed by microscopic urinalysis. After confirmation of bacteriuria and pyuria, a urine culture may be obtained. A urine culture is indicated in complicated or HAI UTIs, persistent bacteriuria, or frequently recurring UTIs (more than two or three episodes per year). Urine may also be cultured when the infection is unresponsive to empiric therapy or the diagnosis is questionable.[5]

A voided midstream technique *(clean-catch urine sample)* is preferred for obtaining a urine culture in most circumstances. For women, teach them to spread the labia and wipe the perurethral area from front to back using a moistened, clean gauze sponge (no antiseptic is used because it could contaminate the specimen and cause false positives). Then tell them to keep the labia spread, start voiding, and collect the specimen 1 to 2 seconds after voiding starts. For men, instruct them to wipe the glans penis around the urethra and collect the specimen 1 to 2 seconds after voiding begins.

Refrigerate urine immediately on collection. The urine should be cultured within 24 hours of refrigeration. A specimen obtained by catheterization provides more accurate results than a clean-catch specimen. When an adequate clean-catch specimen cannot be readily obtained, a catheterization may be necessary.

A urine culture is accompanied by *sensitivity testing* to determine the bacteria's susceptibility to a variety of antibiotic drugs. The results of this test allow the health care provider to select an antibiotic known to be capable of destroying the bacteria causing a UTI in a specific patient.

Imaging studies of the urinary tract are indicated in selected cases. A computed tomography (CT) urogram or ultrasound may be obtained when obstruction of the urinary system is suspected or UTIs recur.

Collaborative Care

Once a UTI has been diagnosed, appropriate antimicrobial therapy is initiated. An antibiotic may be selected based on the health care provider's best judgment *(empiric therapy)* or the results of sensitivity testing.[6] The collaborative care and drug therapy of UTIs are summarized in Table 46-4. Uncomplicated cystitis can be treated by a short-term course of antibiotics, typically for 1 to 3 days. In contrast, complicated UTIs require longer-term treatment, lasting 7 to 14 days or longer.[7,8]

Many residents of long-term care facilities, especially women, have chronic asymptomatic bacteriuria. However, usually only symptomatic UTIs are treated.

First-choice drugs to empirically treat uncomplicated or initial UTIs are trimethoprim/sulfamethoxazole (TMP/SMX) (Bactrim, Septra), nitrofurantoin (Macrodantin), and fosfomycin (Monurol). TMP/SMX has the advantages of being relatively inexpensive and being taken twice daily. A disadvantage is *E. coli* resistance to TMP/SMX, which is an increasing problem in the United States. Nitrofurantoin is normally given three or four times daily, but a long-acting preparation (Macrobid) is available that is taken twice daily.

Other antibiotics that may be used to treat uncomplicated UTI include ampicillin, amoxicillin, and cephalosporins. The fluoroquinolones are used to treat complicated UTIs. These drugs include ciprofloxacin (Cipro), levofloxacin (Levaquin), norfloxacin (Noroxin), ofloxacin (Floxin), and gatifloxacin (Tequin). In patients with UTIs secondary to fungi, amphotericin or fluconazole (Diflucan) is the preferred therapy.

DRUG ALERT: Nitrofurantoin (Furadantin, Macrodantin)

- Avoid sunlight. Use sunscreen, and wear protective clothing.
- Notify health care provider immediately if fever, chills, cough, chest pain, dyspnea, rash, or numbness or tingling of fingers or toes develops.

A urinary analgesic such as oral phenazopyridine (Azo-Standard, Pyridium) may relieve discomfort caused by severe dysuria. Phenazopyridine is an azo dye excreted in urine, where it exerts a topical analgesic effect on the urinary tract mucosa.

Prophylactic or *suppressive antibiotics* are sometimes given to patients who have repeated UTIs. A low dose of TMP/SMX, nitrofurantoin, or another antibiotic may be taken daily to prevent recurring UTIs, or a single dose may be taken before an event likely to provoke a UTI, such as sexual intercourse. Although suppressive therapy is often effective on a short-term basis, this strategy is limited because of the risk of antibiotic resistance, which ultimately leads to breakthrough infections with increasingly virulent pathogens.

TABLE 46-4 COLLABORATIVE CARE

Urinary Tract Infection

Diagnostic

- History and physical examination
- Urinalysis (obtain midstream, "clean-catch" voided specimen)
- Urine for culture and sensitivity (if indicated)
- Imaging studies of urinary tract (if indicated)
  - CT urogram
  - Intravenous pyelogram (IVP)
  - CT/IVP
  - Cystoscopy
  - Ultrasound

Collaborative Therapy

Uncomplicated UTI

- Antibiotics
  - trimethoprim/sulfamethoxazole (Bactrim, Septra)
  - trimethoprim alone in patients with sulfa allergy
  - nitrofurantoin (Macrodantin, Macrobid)
  - fosfomycin (Monurol)
- Patient teaching
- Adequate fluid intake (six 8-oz glasses/day)

Recurrent, Uncomplicated UTI

- Repeat urinalysis
- Urine culture and sensitivity testing
- Imaging study of urinary tract (if indicated)
- Antibiotic: trimethoprim/sulfamethoxazole, nitrofurantoin
- Sensitivity-guided antibiotic therapy: ampicillin, amoxicillin, first-generation cephalosporin, fluoroquinolones
- Consider 3- to 6-mo trial of suppressive or prophylactic antibiotic regimen
- Consider postcoital antibiotic prophylaxis: trimethoprim/sulfamethoxazole, nitrofurantoin, cephalexin
- Adequate fluid intake (six 8-oz glasses/day)
- Repeat patient teaching

NURSING MANAGEMENT URINARY TRACT INFECTION

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with a UTI are presented in Table 46-5.

NURSING DIAGNOSES

Nursing diagnoses for the patient with a UTI may include, but are not limited to, the following:

- Impaired urinary elimination *related to* the effects of UTI
- Readiness for enhanced self-health management

Additional information on nursing diagnoses for the patient with a UTI is presented in eNursing Care Plan 46-1 (on the website for this chapter).

TABLE 46-5 NURSING ASSESSMENT

Urinary Tract Infection

Subjective Data

Important Health Information

Past health history: Previous urinary tract infections; urinary calculi, stasis, reflux, strictures, or retention; neurogenic bladder; pregnancy; benign prostatic hyperplasia; sexually transmitted infection; bladder cancer

Medications: Antibiotics, anticholinergics, antispasmodics

Surgery or other treatments: Recent urologic instrumentation (catheterization, cystoscopy, surgery)

Functional Health Patterns

Health perception–health management: Urinary hygiene practices; lassitude, malaise

Nutritional-metabolic: Nausea, vomiting, anorexia; chills

Elimination: Urinary frequency, urgency, hesitancy; dysuria, nocturia

Cognitive-perceptual: Suprapubic or low back pain, costovertebral tenderness; bladder spasms, dysuria, burning on urination

Sexuality-reproductive: Multiple sex partners (women), use of spermicidal agents or contraceptive diaphragm (women)

Objective Data

General

Fever, chills, dysuria

Atypical presentation in older adults: afebrile, absence of dysuria, loss of appetite, altered mental status

Urinary

Hematuria; cloudy, foul-smelling urine; tender, enlarged kidney

Possible Diagnostic Findings

Leukocytosis; UA positive for bacteria, pyuria, RBCs, WBCs, and nitrites; positive urine culture; IVP, CT scan, US, VCUG, and cystoscopy indicating urinary tract abnormalities

IVP, Intravenous pyelogram; *VCUG,* voiding cystourethrogram.

PLANNING

The overall goals are that the patient with a UTI will have (1) relief from bothersome LUTS, (2) prevention of upper urinary tract involvement, and (3) prevention of recurrence.

NURSING IMPLEMENTATION

HEALTH PROMOTION. It is important to recognize individuals who are at risk for a UTI. These people include debilitated persons, older adults, patients who are immunocompromised (e.g., cancer, human immunodeficiency virus [HIV], diabetes mellitus), and patients treated with immunosuppressive drugs or corticosteroids. Health promotion activities, particularly for these individuals, can help decrease the frequency of infections and provide for early detection of infection. Health promotion activities include teaching preventive measures such as (1) emptying the bladder regularly and completely, (2) evacuating the bowel regularly, (3) wiping the perineal area from front to back after urination and defecation, and (4) drinking an adequate amount of liquid each day.

To estimate the amount of fluid intake a person should have in 24 hours, take the person's weight in pounds and divide that number in half. The result is the number of ounces of fluid a person should have per day. Thus a 150-pound person would require 75 oz/day. The person will obtain about 20% of this fluid from food, which leaves 60 oz (1775 mL) obtained by drinking, or just over seven 8-oz glasses of fluid.

Daily intake of cranberry juice or cranberry tablets or capsules may reduce the number of UTIs (see Evidence-Based Practice box). It is thought that enzymes found in cranberries inhibit attachment of urinary pathogens (especially *E. coli*) to the bladder wall.[9]

EVIDENCE-BASED PRACTICE

Translating Research Into Practice

Do Cranberry Products Prevent Urinary Tract Infections?

Clinical Question

Among adults and children (P), what is the effect of cranberry-containing products (I) vs. placebo vs. nonplacebo control (C) in preventing urinary tract infections (O)?

Best Available Evidence

Systematic review of randomized controlled trials (RCTs)

Critical Appraisal and Synthesis of Evidence

- Thirteen RCTs ($n = 1616$) of patients at high risk for recurrent urinary tract infections (UTIs), including women, older adults, patients with neuropathic bladder, and pregnant women. Children were also studied.
- Cranberry products were juice, capsules, or tablets given for 6 mo in most cases.
- Cranberry-containing products had a positive effect in preventing symptomatic UTIs.
- These products showed greater effect in women (especially those with recurrent UTIs), children, cranberry juice drinkers, and those taking the products more than twice daily.

Conclusion

- Cranberry-containing products can prevent UTIs.
- Cranberry juice was more effective than cranberry capsules. This may be due to increased hydration from the juice.

Implications for Nursing Practice

- Inform patients who are at an increased risk for recurrent UTIs that cranberry products have a protective effect in reducing UTIs.
- Cranberry juice works by preventing the attachment of bacteria to the epithelial cells in the bladder wall.
- Emphasize the importance of adequate fluid intake, including drinking cranberry juice.

P, Patient population of interest; *I,* intervention or area of interest; *C,* comparison of interest or comparison group; *O,* outcomes of interest (see p. 12).

All patients undergoing instrumentation of the urinary tract are at risk for developing an HAI UTI. You have a major role in the prevention of these infections.[10-12] Avoidance of unnecessary catheterization and early removal of indwelling catheters are the most effective means for reducing HAI UTIs. Always follow aseptic technique during these procedures. Wash your hands before and after contact with each patient.[13] Wear gloves for care involving the urinary system. When a catheter has been inserted, use special measures, as explained in the section on urethral catheterization later in this chapter on p. 1092.

Routine and thorough perineal hygiene is important for all hospitalized patients, especially when a bedpan is used, after a bowel movement, or if fecal incontinence is present. Answer call lights quickly and offer the bedpan or urinal to bedridden patients at frequent intervals. These measures can prevent incontinence and decrease the number of incontinent episodes.

ACUTE INTERVENTION. Acute intervention for a patient with a UTI includes ensuring adequate fluid intake if it is not contraindicated. Maintaining adequate fluid intake may be difficult because of the patient's perception that fluid intake will worsen the discomfort and urinary frequency associated with a UTI. Tell patients that fluids will increase frequency of urination at first but will also dilute the urine, making the bladder less irritable. Fluids will help flush out bacteria before they have a chance to colonize in the bladder. Caffeine, alcohol, citrus juices, chocolate, and highly spiced foods or beverages should be avoided because they are potential bladder irritants.

Application of local heat to the suprapubic area or lower back may relieve the discomfort associated with a UTI. Advise the patient to apply a heating pad (turned to its lowest setting) against the back or suprapubic area. A warm shower or sitting in a tub of warm water filled above the waist can also provide temporary relief.

Instruct the patient about the prescribed drug therapy, including side effects. Emphasize the importance of taking the full course of antibiotics. Often patients stop antibiotic therapy once symptoms disappear. This can lead to inadequate treatment and recurrence of infection or bacterial resistance to antibiotics.

Sometimes a second drug or a reduced dosage of drug is ordered after the initial course to suppress bacterial growth in patients susceptible to recurrent UTI. Instruct the patient to monitor for signs of improvement (e.g., cloudy urine becomes clear) and a decrease in or cessation of symptoms. Teach patients to promptly report any of the following to their health care provider: (1) persistence of bothersome LUTS beyond the antibiotic treatment course, (2) onset of flank pain, or (3) fever.

AMBULATORY AND HOME CARE. Home care for the patient with a UTI should emphasize the importance of adhering to the drug regimen. Your responsibility is to teach the patient and caregiver about the need for ongoing care (Table 46-6). This includes taking antimicrobial drugs as ordered, maintaining adequate daily fluid intake, voiding regularly (approximately every 3 to 4 hours), urinating before and after intercourse, and temporarily discontinuing the use of a diaphragm.

TABLE 46-6 PATIENT & CAREGIVER TEACHING GUIDE

Urinary Tract Infection

When teaching a patient and caregiver measures to prevent a recurrence of a urinary tract infection (UTI), include the following.

1. Take all antibiotics as prescribed. Symptoms may improve after 1-2 days of therapy, but organisms may still be present.
2. Practice appropriate hygiene, including the following:
   - Carefully clean the perineal region by separating the labia when cleansing.
   - Wipe from front to back after urinating.
   - Cleanse with warm soapy water after each bowel movement.
3. Empty the bladder before and after sexual intercourse.
4. Urinate regularly, approximately every 3-4 hr during the day.
5. Maintain adequate fluid intake.
6. Avoid vaginal douches and harsh soaps, bubble baths, powders, and sprays in the perineal area.
7. Report to the health care provider symptoms or signs of recurrent UTI (e.g., fever, cloudy urine, pain on urination, urgency, frequency).
8. Consider drinking unsweetened cranberry juice (8 oz three times a day) or taking cranberry extract tablets 300-400 mg/day for UTI prevention.

If treatment is complete and the symptoms are still present, instruct the patient to get follow-up care. Recurrent symptoms because of bacterial persistence or inadequate treatment typically occur within 1 to 2 weeks after completion of therapy. If the patient has followed the treatment regimen, a relapse indicates the need for further evaluation.[14]

EVALUATION

The expected outcomes are that the patient with a UTI will

- Experience normal urinary elimination patterns
- Report relief of bothersome urinary tract symptoms
- Verbalize knowledge of treatment regimen

Additional information on the expected outcomes for the patient with a UTI is presented in eNursing Care Plan 46-1 (on the website for this chapter).

ACUTE PYELONEPHRITIS

Etiology and Pathophysiology

Pyelonephritis is an inflammation of the renal parenchyma (Fig. 46-2) and collecting system (including the renal pelvis). The most common cause is bacterial infection, but fungi, protozoa, or viruses can also infect the kidney.

Urosepsis is a systemic infection arising from a urologic source. Its prompt diagnosis and effective treatment are critical because it can lead to septic shock and death in 15% of cases unless promptly eradicated. Septic shock is the outcome of unresolved bacteremia involving a gram-negative organism. (Septic shock is discussed in Chapter 67.)

Pyelonephritis usually begins with colonization and infection of the lower urinary tract via the ascending urethral route. Bacteria normally found in the intestinal tract, such as *E. coli* or *Proteus, Klebsiella,* or *Enterobacter* species, frequently cause pyelonephritis. A preexisting factor is often present such as *vesicoureteral reflux* (retrograde, or backward, movement of urine from lower to upper urinary tract) or dysfunction of the lower urinary tract (e.g., obstruction from benign prostatic hyperplasia [BPH], a stricture, a urinary stone). For residents of long-term care facilities, urinary tract catheterization is a common cause of pyelonephritis and urosepsis.

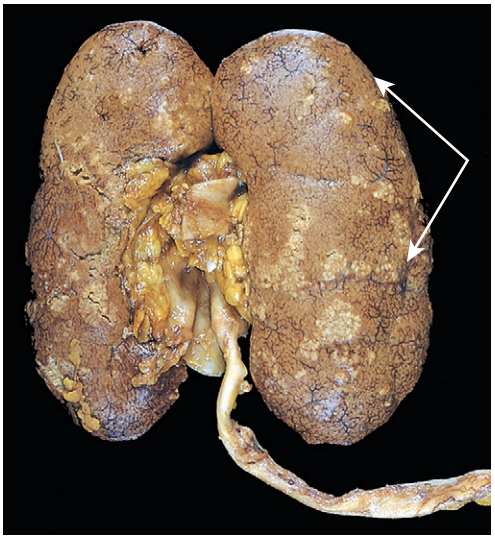

FIG. 46-2 Acute pyelonephritis. Cortical surface shows grayish white areas of inflammation and abscess formation *(arrows).*

Acute pyelonephritis commonly starts in the renal medulla and spreads to the adjacent cortex. One of the most important risk factors for acute pyelonephritis is pregnancy-induced physiologic changes in the urinary system. Recurring episodes of pyelonephritis, especially in the presence of obstructive abnormalities, can lead to *chronic pyelonephritis* (discussed below).

Clinical Manifestations and Diagnostic Studies

The clinical manifestations of acute pyelonephritis vary from mild fatigue to the sudden onset of chills; fever; vomiting; malaise; flank pain; and the LUTS characteristic of cystitis, including dysuria, urgency, and frequency. *Costovertebral tenderness* to percussion (costovertebral angle [CVA] pain) is typically present on the affected side. Although the clinical manifestations may subside within a few days, even without specific therapy, bacteriuria and pyuria usually persist.

Urinalysis results indicate pyuria, bacteriuria, and varying degrees of hematuria. WBC casts may be found in the urine, indicating involvement of the renal parenchyma. A complete blood count shows leukocytosis and a shift to the left with an increase in bands (immature neutrophils). Urine cultures must be obtained when pyelonephritis is suspected. In patients with more severe illness who are hospitalized, blood cultures are usually obtained as well.

Ultrasonography of the urinary system may be performed to identify anatomic abnormalities, hydronephrosis, renal abscesses, or an obstructing stone. CT urograms are also used to assess for signs of infection in the kidney and complications of pyelonephritis, such as impaired renal function, scarring, chronic pyelonephritis, or abscesses.

Collaborative Care

The diagnostic tests and collaborative therapy of acute pyelonephritis are summarized in Table 46-7. Patients with severe infections or complicating factors such as nausea and vomiting with dehydration require hospitalization.

The patient with mild symptoms may be treated as an outpatient with antibiotics for 14 to 21 days (see Table 46-7). Parenteral antibiotics are often given initially in the hospital to rapidly establish high serum and urinary drug levels. When initial treatment resolves acute symptoms and the patient is able to tolerate oral fluids and drugs, the person may be discharged on a regimen of oral antibiotics for an additional 14 to 21 days. Symptoms and signs typically improve or resolve within 48 to 72 hours after starting therapy.

Relapses may be treated with a 6-week course of antibiotics. Antibiotic prophylaxis may also be used for recurrent infections. The effectiveness of therapy is evaluated based on the presence or absence of bacterial growth on urine culture.

Urosepsis is characterized by bacteriuria and bacteremia (bacteria in blood). Close observation and vital sign monitoring are essential. Prompt recognition and treatment of septic shock may prevent irreversible damage or death.

NURSING MANAGEMENT ACUTE PYELONEPHRITIS

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with pyelonephritis are similar to those for the patient with a UTI (see Table 46-5).

TABLE 46-7 COLLABORATIVE CARE

Acute Pyelonephritis

Diagnostic

- History and physical examination
- Urinalysis
- Urine for culture and sensitivity
- Imaging studies: ultrasound (initially), CT scan, IVP, CT/IVP, VCUG, radionuclide imaging
- CBC count with WBC differential
- Blood culture (if bacteremia is suspected)
- Percussion for flank (costovertebral angle [CVA]) pain

Collaborative Therapy

Mild Symptoms (Uncomplicated Infection)

- Outpatient management or short hospitalization
  - Empirically selected broad-spectrum antibiotics: ampicillin, vancomycin combined with an aminoglycoside (e.g., tobramycin [Nebcin], gentamicin [Garamycin])
  - Switch to sensitivity-guided therapy: trimethoprim/sulfamethoxazole (Bactrim, Septra) when results of urine and blood culture are available
- Fluoroquinolones: ciprofloxacin (Cipro), ofloxacin (Floxin), norfloxacin (Noroxin), gatifloxacin (Tequin)
- Adequate fluid intake
- Nonsteroidal antiinflammatory drugs (NSAIDs) or antipyretic drugs
- Follow-up urine culture and imaging studies

Severe Symptoms

- Hospitalization
- Parenteral antibiotics
  - Empirically selected broad-spectrum antibiotics: ampicillin, vancomycin combined with an aminoglycoside (e.g., tobramycin, gentamicin)
  - Switch to sensitivity-guided antibiotic therapy when results of urine and blood culture are available
- Oral antibiotics when patient tolerates oral intake
- Adequate fluid intake (parenteral initially; switch to oral fluids as nausea, vomiting, and dehydration subside)
- NSAIDs or antipyretic drugs to reverse fever and relieve discomfort
- Urinary analgesics (as above)
- Follow-up urine culture and imaging studies

IVP, Intravenous pyelogram; *VCUG,* voiding cystourethrogram.

NURSING DIAGNOSES

Nursing diagnoses for the patient with pyelonephritis include, but are not limited to, those for the patient with a UTI (see p. 1067).

PLANNING

The overall goals are that the patient with pyelonephritis will have (1) normal renal function, (2) normal body temperature, (3) no complications, (4) relief of pain, and (5) no recurrence of symptoms.

NURSING IMPLEMENTATION

Health promotion and maintenance measures are similar to those for cystitis (see p. 1072). Early treatment for cystitis can prevent ascending infections. Because patients with structural abnormalities of the urinary tract are at high risk for infection, stress the need for regular medical care.

Nursing interventions vary depending on the severity of symptoms. These interventions include teaching the patient about the disease process with emphasis on (1) continuing medications as prescribed, (2) having a follow-up urine culture, and (3) recognizing manifestations of recurrence or relapse (see

Table 46-6). In addition to antibiotic therapy, encourage the patient to drink at least eight glasses of fluid every day, even after the infection has been treated. Rest will increase patient comfort. The patient who has frequent relapses or reinfections may be treated with long-term, low-dose antibiotics. Making certain the patient understands the rationale for therapy is important to increase adherence.

EVALUATION

The expected outcomes for the patient with pyelonephritis are the same as for UTI (see p. 1069).

CHRONIC PYELONEPHRITIS

In *chronic pyelonephritis* the kidneys become small, atrophic, and shrunken and lose function due to fibrosis (scarring). Chronic pyelonephritis is usually the result of recurring infections involving the upper urinary tract. However, it may also occur in the absence of an existing infection, recent infection, or history of UTIs.

Radiologic imaging and a biopsy, rather than clinical features, are used to confirm the diagnosis of chronic pyelonephritis. Imaging studies reveal a small, fibrotic kidney. The collecting system may be small or hydronephrotic. Biopsy results indicate the loss of functioning nephrons, infiltration of the parenchyma with inflammatory cells, and fibrosis.

The level of renal function in chronic pyelonephritis depends on whether one or both kidneys are affected, the extent of scarring, and the presence of coexisting infection. Chronic pyelonephritis often progresses to end-stage kidney (renal) disease (ESKD) even if the underlying infection is successfully treated. Nursing and collaborative management of the patient with chronic kidney disease is discussed in Chapter 47.

URETHRITIS

Urethritis is an inflammation of the urethra. Causes of urethritis include a bacterial or viral infection, *Trichomonas* and monilial infection (especially in women), chlamydial infection, and gonorrhea (especially in men).

In men the causes of urethritis are usually sexually transmitted. Purulent discharge usually indicates a gonococcal urethritis, whereas a clear discharge typically signifies a nongonococcal urethritis. (Sexually transmitted infections are discussed in Chapter 53.) Urethritis also produces bothersome LUTS, including dysuria, urgency, and frequent urination, similar to those seen with cystitis.

In women, urethritis is difficult to diagnose. It frequently produces bothersome LUTS, but urethral discharge may not be present.

Treatment of urethritis is based on identifying and treating the cause and providing symptomatic relief. Drugs used for bacterial infections include TMP/SMX and nitrofurantoin. Metronidazole (Flagyl) and clotrimazole (Mycelex) may be used for treating *Trichomonas* infection. Drugs such as nystatin (Mycostatin) or fluconazole may be prescribed for monilial infections. In chlamydial infections, doxycycline (Vibramycin) may be used. Women with negative urine cultures and no pyuria usually do not respond to antibiotics.

Warm sitz baths may temporarily relieve bothersome symptoms. Instruct the patient to avoid using vaginal deodorant sprays, properly cleanse the perineal area after bowel movements and urination, and avoid sexual intercourse until symptoms subside. Teach patients with sexually transmitted urethritis to refer their sex partners for evaluation and testing if they had sexual contact in the 60 days preceding the onset of the patient's symptoms or diagnosis.

URETHRAL DIVERTICULA

Urethral diverticula are localized outpouchings of the urethra. Most often they result from enlargement of obstructed periurethral glands. In women, who have a higher incidence than men, the diverticula protrude into the anterior vaginal wall. The rare cases reported in males generally have been associated with lower urinary tract congenital anomalies or surgical trauma.

The periurethral glands are found along the entire length of the urethra, with the majority draining into the distal third of the urethra. Skene's glands are the largest of these glands. Causes of urethral diverticuli include urethral trauma from childbearing, urethral instrumentation, urethral dilation, and infection with gonococcal organisms.

Symptoms include dysuria, postvoid dribbling, frequent urination (more often than every 2 hours), urgency, suprapubic discomfort or pressure, dyspareunia, and a feeling of incomplete bladder emptying. Urinary incontinence is frequently present. However, many women have no symptoms.

The urine may contain gross blood (hematuria) or sediment, which gives it a cloudy appearance. An anterior vaginal wall mass may be felt on physical examination. When palpated, the mass is often quite tender and expresses purulent discharge through the urethra.

Radiographic studies such as voiding cystourethrography (VCUG) can be used to confirm the diagnosis. Additional studies include ultrasound and magnetic resonance imaging (MRI) to determine the size of the diverticulum in relation to the urethral lumen.

Surgical options include transurethral incision of the diverticular neck, marsupialization (creation of a permanent opening) of the diverticular sac into the vagina (often referred to as a Spence procedure), and surgical excision. Stress urinary incontinence is a potential complication of the surgery.

INTERSTITIAL CYSTITIS/ PAINFUL BLADDER SYNDROME

Interstitial cystitis (IC) is a chronic, painful inflammatory disease of the bladder characterized by symptoms of urgency, frequency, and pain in the bladder and/or pelvis. *Painful bladder syndrome* (PBS) is suprapubic pain related to bladder filling. The term *IC/PBS* refers to cases of urinary pain that cannot be attributed to other causes such as infection or urinary calculi.

IC/PBS is more common in women than men. It affects about 3.3 million women and 1.6 million men.[15]

The etiology of IC/PBS remains unknown and is likely multifactorial. Possible causes include neurogenic hypersensitivity of the lower urinary tract, alterations in mast cells in the muscle and/or mucosal layers of the bladder, infection with an unusual organism (e.g., slow-growing virus), or production of a toxic substance in the urine.[16]

The bladder wall may be irritated and inflamed, and can become scarred. *Glomerulations* (superficial ulcerations with pinpoint bleeding) often occur on the bladder wall.

Clinical Manifestations and Diagnostic Studies

The two primary clinical manifestations of IC/PBS are pain and bothersome LUTS (e.g., frequency, urgency). The pain is usually located in the suprapubic area but may involve the vagina, labia, or entire perineal region, including the rectum and anus. The pain varies from moderate to severe and is exacerbated by bladder filling, postponed urination, physical exertion, pressure against the suprapubic area, certain foods, or emotional distress. The pain is transiently relieved by urination. Bothersome LUTS are similar to a UTI, and the condition is often misdiagnosed as a recurring or chronic UTI or, in men, chronic prostatitis.

The patient experiences periods of remission and exacerbation of the pain and bothersome voiding symptoms. Women often report that pain occurs premenstrually and is aggravated by sexual intercourse or emotional stress. Some patients experience symptoms that disappear altogether after a period of weeks to months, whereas others have persistent symptoms over months to years.

IC/PBS is a diagnosis of exclusion.[17] A careful history and physical examination are necessary to rule out other disorders that produce similar symptoms, such as UTI or endometriosis. Urine cultures do not find any bacteria or other organisms in the urine. Furthermore, people with IC/PBS do not respond to antibiotic therapy. Cystoscopic examination may reveal a small bladder capacity and glomerulations, but these findings are frequently not present in patients with IC/PBS.

Collaborative Care

Because the etiology of IC/PBS is unknown, no single treatment consistently reverses or relieves symptoms. Various therapies have been effective, including nutritional and drug therapy.[18,19] Surgical therapy is rarely indicated.

Elimination of foods and beverages that are likely to irritate the bladder may provide some relief from symptoms. Typical bladder irritants include caffeine; alcohol; citrus products; aged cheeses; nuts; foods containing vinegar, curries, or hot peppers; and foods or beverages, including fruits (cranberries), likely to lower urinary pH. Recipes and menus for a well-balanced diet that is specifically designed to avoid bladder-irritating foods and beverages are available at the website for the Interstitial Cystitis Association *(www.ichelp.org)*.

Advise patients that an over-the-counter (OTC) dietary supplement called calcium glycerophosphate (Prelief) alkalinizes the urine and can provide relief from the irritating effects of certain foods. This agent may be particularly helpful when dining away from home, where the patient has less control over food preparation.

Because stress can exacerbate or cause flare-ups of IC/PBS symptoms, stress management techniques such as relaxation breathing and imagery (see Chapter 7) may be helpful. Using lubrication or altering positions may decrease pain associated with sexual intercourse.

Two tricyclic antidepressants, amitriptyline (Elavil) and nortriptyline (Aventyl), are used to reduce the burning pain and urinary frequency. Pentosan (Elmiron) is the only oral agent approved for the treatment of patients with symptoms of IC. It enhances the protective effects of the glycosaminoglycan layer of the bladder, and is thought to relieve pain associated with IC/PBS by reducing the irritative effects of urine on the bladder wall. These drugs are used to provide relief over time (weeks to months), but do not provide the immediate relief that may be needed for an acute exacerbation of symptoms. A short course of opioid analgesics may be used for immediate relief.

Dimethyl sulfoxide (DMSO) can be directly instilled into the bladder through a small catheter. This drug desensitizes pain receptors in the bladder wall. Heparin and hyaluronic acid also may be instilled into the bladder to relieve IC/PBS symptoms. Like pentosan, they are thought to enhance the protective properties of the glycosaminoglycan layer of the bladder. Instillations are often administered with lidocaine, which rapidly desensitizes the bladder wall, helping the patient tolerate instillation of additional heparin or hyaluronic acid and providing transient relief from pain.

Several surgical procedures can be used to relieve severe, debilitating pain. Surgical urinary diversion, such as an ileal conduit, is used when other measures fail. Unfortunately, some patients have reported pain within the urinary diversion, possibly indicating that some factor in the urine may contribute to IC/PBS in certain cases.

NURSING MANAGEMENT INTERSTITIAL CYSTITIS/ PAINFUL BLADDER SYNDROME

Assess the characteristics of the pain associated with IC/PBS. Ask the patient about specific dietary or lifestyle factors that exacerbate or alleviate pain, and assess the intensity of the pain. Instruct the patient to keep a bladder log or voiding diary over a period of at least 3 days to determine voiding frequency and patterns of nocturia. Keeping a pain record at the same time may be useful.

A UTI may occur during the course of IC/PBS management because of diagnostic instrumentation and frequent bladder instillations. A UTI is likely to produce an acute exacerbation of bothersome LUTS and urinary frequency, as well as dysuria (not typically associated with IC/PBS) and odorous urine, possibly with hematuria.

Instruct the patient to maintain good nutrition, particularly in light of the broad dietary restrictions often necessary to control IC-related pain. Advise the patient to take a multivitamin containing no more than the recommended dietary allowance for essential vitamins and to avoid high-potency vitamins because they may irritate the bladder. Advise the patient to avoid clothing that creates suprapubic pressure, including pants with tight belts or restrictive waistlines.

Written educational materials about diet, ways to cope with the need for frequent urination, and strategies for coping with the emotional burden of IC/PBS are available from the Interstitial Cystitis Association *(www.ichelp.com)*. Reassurance that IC/PBS is a real condition experienced by others and that it can be treated may relieve the anxiety, anger, guilt, and frustration related to experiences of chronic pain and voiding dysfunction in the absence of a clear-cut diagnosis and treatment strategy.

RENAL TUBERCULOSIS

Renal tuberculosis (TB) is rarely a primary lesion. It is usually secondary to TB of the lung. In a small percentage of patients with pulmonary TB, the tubercle bacilli reach the kidneys via the bloodstream. Onset occurs 5 to 8 years after the primary lung infection.[20] When the kidney is initially infected with bacilli, the patient is often asymptomatic. Sometimes the patient complains of fatigue and develops a low-grade fever. As the

lesions ulcerate, infection descends to the bladder and other genitourinary organs. Then the patient experiences cystitis, frequent urination, burning on voiding, and epididymitis (in men).

Symptoms of a UTI are the first manifestations in the majority of patients with renal TB. Renal lesions may calcify as they heal. Infrequently, renal colic, lumbar and iliac pain, and hematuria may be present.

Tuberculin skin test results are positive in most patients, but this finding only indicates that the person has had previous inhalation of mycobacteria rather than active disease. A diagnosis of renal TB is based on finding tubercle bacilli in the urine.

Radiographic tests that may be done include CT urogram, CT/intravenous pyelogram (IVP), and voiding cystourethrogram (VCUG). These studies help determine the extent and severity of the disease.

Long-term complications of renal TB depend on the duration of the disease. Scarring of the renal parenchyma and the development of ureteral strictures occur. The earlier treatment is initiated, the less likely renal failure will develop. The patient may require long-term urologic follow-up. Nursing and collaborative management for the patient with TB is discussed in Chapter 28.

IMMUNOLOGIC DISORDERS OF KIDNEY

GLOMERULONEPHRITIS

Immunologic processes involving the urinary tract predominantly affect the renal glomerulus. The disease process results in **glomerulonephritis** (inflammation of the glomeruli), which affects both kidneys equally and is the third leading cause of ESKD in the United States. Although the glomerulus is the primary site of inflammation, tubular, interstitial, and vascular changes also occur.

A variety of conditions can cause glomerulonephritis, ranging from kidney infections to systemic diseases (Table 46-8). Glomerulonephritis can be acute or chronic. With *acute glomerulonephritis,* symptoms come on suddenly and may be temporary or reversible. An example of this is acute poststreptococcal glomerulonephritis (discussed in the next section).

TABLE 46-8 CAUSES OR RISK FACTORS FOR GLOMERULONEPHRITIS

Cause or Risk Factor	Description
Infections	
Poststreptococcal glomerulonephritis	• GN may develop 1-2 wk after a streptococcal throat infection or, rarely, a skin infection (impetigo). • Antibodies (Ab) to strep antigen (Ag) develop and the Ag-Ab deposit in the glomeruli, causing inflammation.
Infective endocarditis	• Bacteria can cause an infection of one or more of the heart valves (see Chapter 37). • People at risk include those with a heart defect, such as a damaged or artificial heart valve. • Bacterial endocarditis is associated with GN, but the exact cause is not known.
Viral infections	• Viral infections can trigger GN. • Common viruses include human immunodeficiency virus (HIV) and hepatitis B and hepatitis C viruses.
Immune Diseases	
Systemic lupus erythematosus (SLE)	• Autoimmune disorder characterized by the involvement of several tissues and organs, particularly joints, skin, and kidneys (see Chapter 65). • GN frequently occurs in SLE and has a poor prognosis.
Scleroderma	• Disease of unknown etiology characterized by widespread alterations of connective tissue and by vascular lesions in many organs (see Chapter 65). • In the kidney, vascular lesions are associated with fibrosis. Severity of renal involvement varies.
Goodpasture syndrome	• Autoimmune disorder that causes lung and kidney disease. • Causes bleeding into the lungs and GN.
IgA nephropathy	• Results from deposits of immunoglobulin A (IgA) in the glomeruli. • Characterized by recurrent episodes of hematuria.
Vasculitis	
Polyarteritis	• Autoimmune disease that affects small and medium blood vessels. • Can affect any organ but common in heart, kidneys, and intestines.
Wegener's granulomatosis	• Form of vasculitis affecting small and medium blood vessels. • Most commonly affects kidneys, lungs, and upper respiratory tract.
Conditions Causing Scarring of Glomeruli	
Diabetic nephropathy	• Primary cause of end-stage kidney disease in the United States (see Chapter 47). • Microvascular changes of diffuse glomerulosclerosis involving thickening of the glomerular basement membrane.
Hypertension	• Nephrosclerosis is a complication of hypertension. • GN can also cause hypertension.
Focal segmental glomerulosclerosis	• Characterized by scattered scarring of some of the glomeruli. • May result from another disease or occur for unknown reasons.
Other Causes	
Amyloidosis	• Caused by infiltration of tissues with amyloid (hyaline substance). • Hyaline bodies consist largely of protein. • Kidney involvement is common, and proteinuria is often the first clinical manifestation.
Illegal drug use	• People who use these drugs are at increased risk for GN.

GN, Glomerulonephritis.

Chronic glomerulonephritis is slowly progressive glomerulonephritis generally leading to irreversible renal failure (discussed later in this chapter).

Acute Poststreptococcal Glomerulonephritis

Acute poststreptococcal glomerulonephritis (APSGN) is a common type of acute glomerulonephritis. It is most common in children and young adults, but all age-groups can be affected. APSGN develops 5 to 21 days after an infection of the tonsils, pharynx, or skin (e.g., streptococcal sore throat, impetigo) by nephrotoxic strains of group A β-hemolytic streptococci. The person produces antibodies to the streptococcal antigen. Although the specific mechanism is not known, tissue injury occurs as the antigen-antibody complexes are deposited in the glomeruli, complement is activated (see Chapter 12), and inflammation results.

The clinical manifestations of APSGN include generalized body edema, hypertension, oliguria, hematuria with a smoky or rusty appearance, and proteinuria. Fluid retention occurs as a result of decreased glomerular filtration. Initially edema appears in low-pressure tissues, such as those around the eyes (periorbital edema), but later it progresses to involve the total body as ascites or peripheral edema in the legs. Smoky urine indicates bleeding in the upper urinary tract. The degree of proteinuria varies with the severity of the glomerulonephropathy. Hypertension primarily results from increased extracellular fluid volume. The patient with APSGN may have abdominal or flank pain. At times the patient has no symptoms, with the problem found on routine urinalysis.

More than 95% of patients with APSGN recover completely or improve rapidly with conservative management. Accurate recognition and assessment are critical, since chronic glomerulonephritis develops in 5% to 15% of the affected persons, and irreversible renal failure occurs in 1% of patients.[21]

The diagnosis of APSGN is based on a complete history and physical examination. An immune response to the streptococci is often demonstrated by assessment of antistreptolysin-O (ASO) titers. The finding of decreased complement components (especially C3 and CH50) indicates an immune-mediated response. A renal biopsy may be done to confirm the disease.

Dipstick urinalysis and urine sediment microscopy reveal erythrocytes in significant numbers. Erythrocyte casts are highly suggestive of APSGN. Proteinuria may range from mild to severe. Blood tests include blood urea nitrogen (BUN) and serum creatinine to assess the extent of renal impairment.

NURSING AND COLLABORATIVE MANAGEMENT
ACUTE POSTSTREPTOCOCCAL GLOMERULONEPHRITIS

The management of APSGN focuses on symptomatic relief. Rest is recommended until the signs of glomerular inflammation (proteinuria, hematuria) and hypertension subside. Edema is treated by restricting sodium and fluid intake and by administrating diuretics. Severe hypertension is treated with antihypertensive drugs. Dietary protein intake may be restricted if there is evidence of an increase in nitrogenous wastes (e.g., elevated BUN). The dietary protein restriction varies with the degree of proteinuria. Low-protein, low-sodium, fluid-restricted diets are discussed in Chapter 47.

Antibiotics should be given only if the streptococcal infection is still present. Corticosteroids and cytotoxic drugs have not been shown to be of value in the treatment of APSGN.

One of the most important ways to prevent APSGN is to encourage early diagnosis and treatment of sore throats and skin lesions. If streptococci are found in the culture, treatment with appropriate antibiotic therapy (usually penicillin) is essential. Encourage the patient to take the full course of antibiotics to ensure that the bacteria have been eradicated. Good personal hygiene is an important factor in preventing the spread of cutaneous streptococcal infections.

In most cases, recovery from the acute glomerulonephritis is complete. However, if progressive involvement occurs and chronic glomerulonephritis develops, ESKD results.

Goodpasture Syndrome

Goodpasture syndrome is an autoimmune disease characterized by circulating antibodies against glomerular and alveolar basement membrane. Damage to the kidneys and lungs results when binding of the antibody causes an inflammatory reaction mediated by complement activation (see Chapter 12).

Goodpasture syndrome is a rare disease that is mostly found in young male smokers. The clinical manifestations include flu-like symptoms with pulmonary symptoms such as cough, mild shortness of breath, hemoptysis, crackles, rhonchi, and pulmonary insufficiency. Renal involvement causes hematuria, weakness, pallor, anemia, and renal failure. Pulmonary hemorrhage usually occurs and may precede glomerular abnormalities by weeks or months.

Current management includes corticosteroids, immunosuppressive drugs (e.g., cyclophosphamide [Cytoxan], azathioprine [Imuran]), plasmapheresis (see Chapter 14), and dialysis. Plasmapheresis removes the circulating anti–glomerular basement membrane (GBM) antibodies, and immunosuppressive therapy inhibits further antibody production. Renal transplantation can be attempted after the circulating anti-GBM antibody titer decreases. Although the disease may recur in the transplanted kidney, this is not a contraindication to transplantation.

Nursing management appropriate for a critically ill patient who is experiencing acute kidney injury (see Chapter 47) and respiratory distress (see Chapter 68) is instituted. Death is often secondary to hemorrhage in the lungs and respiratory failure.

Rapidly Progressive Glomerulonephritis

Rapidly progressive glomerulonephritis (RPGN) is a type of glomerular disease characterized by rapid, progressive loss of renal function over days to weeks. In contrast, chronic glomerulonephritis develops insidiously and progresses over many years. The manifestations of RPGN are hypertension, edema, proteinuria, hematuria, and red blood cell (RBC) casts.

RPGN can occur in a variety of situations: (1) as a complication of inflammatory or infectious disease (e.g., APSGN), (2) as a complication of a systemic disease (e.g., systemic lupus erythematosus), (3) as an idiopathic disease, or (4) with the use of certain drugs (e.g., penicillamine).

Treatment is directed toward correction of fluid overload, hypertension, uremia, and inflammatory injury to the kidney. Treatment includes corticosteroids, cytotoxic agents, and plasmapheresis. Dialysis therapy and transplantation are used as maintenance therapy for the patient with RPGN. After kidney transplantation, RPGN may recur.

Chronic Glomerulonephritis

Chronic glomerulonephritis is a syndrome that reflects the end stage of glomerular inflammatory disease. Most types of glo-

merulonephritis and nephrotic syndrome can eventually lead to chronic glomerulonephritis. Some people who develop chronic glomerulonephritis have no history of kidney disease. Frequently the cause of chronic glomerulonephritis is not found. Infrequently, it is an inherited disorder (e.g., Alport syndrome [see p. 1083]).

With chronic glomerulonephritis, symptoms develop slowly over time. Patients are often unaware that progressive kidney impairment is occurring. They do not realize that they have severe kidney impairment until a diagnostic evaluation is done. Chronic glomerulonephritis is often discovered coincidentally with the finding of an abnormality on a urinalysis or elevated blood pressure (BP).

The syndrome is characterized by proteinuria, hematuria, and the slow development of uremia (see Chapter 47) as a result of decreasing renal function. Chronic glomerulonephritis progresses insidiously toward renal failure in 2 to 30 years.

Clinical manifestations of glomerulonephritis include varying degrees of hematuria (ranging from microscopic to gross) and urinary excretion of various formed elements, including RBCs, WBCs, and casts. Proteinuria and elevated BUN and serum creatinine levels are other findings. Sometimes fatigue may be a presenting symptom.

The patient's history provides important information related to glomerulonephritis. Assess exposure to drugs, immunizations, microbial infections, and viral infections such as hepatitis. Also evaluate the patient for more generalized conditions involving immune disorders, such as systemic lupus erythematosus and scleroderma. Commonly the patient has no recollection or history of any renal problems.

Ultrasound and CT scanning are generally preferred as diagnostic measures. However, a renal biopsy may be performed to determine the exact cause of the glomerulonephritis.

Treatment is supportive and symptomatic. Management of chronic kidney disease is discussed in Chapter 47.

NEPHROTIC SYNDROME

Nephrotic syndrome results when the glomerulus is excessively permeable to plasma protein, causing proteinuria that leads to low plasma albumin and tissue edema.

Etiology and Clinical Manifestations

Some of the common causes of nephrotic syndrome are listed in Table 46-9. About one third of patients with nephrotic syndrome have a systemic disease such as diabetes or systemic lupus erythematosus.

The characteristic manifestations of nephrotic syndrome include peripheral edema, massive proteinuria, hypertension, hyperlipidemia, and hypoalbuminemia. Characteristic laboratory findings include decreased serum albumin, decreased total serum protein, and elevated serum cholesterol. The increased glomerular membrane permeability found in nephrotic syndrome is responsible for the massive excretion of protein in the urine. This results in decreased serum protein and subsequent edema formation. Ascites and *anasarca* (massive generalized edema) develop if there is severe hypoalbuminemia.[22]

The diminished plasma oncotic pressure from the decreased serum proteins stimulates hepatic lipoprotein synthesis, which results in hyperlipidemia. Initially, cholesterol and low-density lipoproteins are elevated. Later the triglyceride level is also increased. Fat bodies (fatty casts) commonly appear in the urine.

Immune responses, both humoral and cellular, are altered in nephrotic syndrome. As a result, infection is a primary cause of morbidity and mortality. Calcium and skeletal abnormalities may occur, including hypocalcemia, blunted calcium response to parathyroid hormone, hyperparathyroidism, and osteomalacia.

With nephrotic proteinuria, hypercoagulability results from the urinary loss of anticoagulant proteins. Hypercoagulability with thromboembolism is a serious complication of nephrotic syndrome. The renal vein is the most common site for thrombus formation. Pulmonary emboli occur in about 40% of nephrotic patients with thrombosis.

TABLE 46-9 CAUSES OF NEPHROTIC SYNDROME

Primary Glomerular Disease
- Membranous proliferative glomerulonephritis
- Primary nephrotic syndrome
- Focal glomerulonephritis
- Inherited nephrotic disease

Extrarenal Causes

Multisystem Disease
- Systemic lupus erythematosus
- Diabetes mellitus
- Amyloidosis

Infections
- Bacterial (streptococcal, syphilis)
- Viral (hepatitis, human immunodeficiency virus)
- Protozoal (malaria)

Neoplasms
- Hodgkin's lymphoma
- Solid tumors of lungs, colon, stomach, breast
- Leukemias

Allergens
- Bee sting
- Pollen

Drugs
- penicillamine
- Nonsteroidal antiinflammatory drugs (NSAIDs)
- captopril (Capoten)
- heroin

NURSING AND COLLABORATIVE MANAGEMENT NEPHROTIC SYNDROME

Specific treatment of nephrotic syndrome depends on the cause. The goals are to cure or control the primary disease and relieve the symptoms. Corticosteroids and cyclophosphamide may be used for the treatment of nephrotic syndrome. Prednisone has been effective to varying degrees for some causes of nephrotic syndrome (e.g., membranous glomerulonephritis, lupus nephritis). Management of diabetes and treatment of edema are measures used for nephrotic syndrome related to diabetes.

Management of the edema includes the cautious use of angiotensin-converting enzyme inhibitors; nonsteroidal antiinflammatory drugs (NSAIDs); and a low-sodium (2 to 3 g/day), moderate-protein (1 to 2 g/kg/day) diet. If urine protein losses are high (more than 10 g/day), additional protein may be recommended.

Dietary salt restrictions are a key to managing edema. Some individuals may need thiazide or loop diuretics.

The treatment of hyperlipidemia includes lipid-lowering agents, such as colestipol (Colestid) and lovastatin (Mevacor) (see Table 34-5). If thrombosis is detected, anticoagulant therapy may be needed.

A major nursing intervention for a patient with nephrotic syndrome focuses on the management of edema. Assess the edema by weighing the patient daily, accurately recording intake

and output, and measuring abdominal girth or extremity size. Compare this information on a daily basis to assess the effectiveness of treatment. Clean the edematous skin carefully. Avoid trauma to the skin. Monitor the effectiveness of diuretic therapy.

Patients with nephrotic syndrome are usually anorexic and have the potential to become malnourished from the excessive loss of protein in the urine. Serve small, frequent meals in a pleasant setting to encourage better dietary intake.

Because the patient with nephrotic syndrome is susceptible to infection, teach the patient to avoid exposure to persons with known infections. Support for the patient, in terms of coping with an altered body image, is essential because of the embarrassment and shame often associated with the edematous appearance.

OBSTRUCTIVE UROPATHIES

Urinary obstruction refers to any anatomic or functional condition that blocks or impedes the flow of urine (Fig. 46-3). It may be congenital or acquired. Damaging effects from urinary tract obstruction affect the system above the level of the obstruction. The severity of these effects depends on the location, duration of obstruction, amount of pressure or dilation, and presence of urinary stasis or infection. Infection increases the risk of irreversible damage.

When obstruction occurs at the level of the bladder neck or prostate, significant bladder changes can occur. Detrusor muscle fibers *hypertrophy* (increase in size) to contract harder to push urine out a narrower pathway. Over a long period, the detrusor loses its ability to compensate for this resistance, eventually leading to large residual urine volume in the bladder.

When *bladder outlet obstruction* is present, pressure increases during bladder filling or storage and can be transmitted to the ureter. This pressure leads to *reflux* (a backflow of urine), **hydroureter** (ureteral dilation and distention), vesicoureteral reflux (backflow, or backward movement, of urine from the lower to upper urinary tract), and **hydronephrosis** (dilation or enlargement of the renal pelvises and calyces) (Fig. 46-4). Chronic pyelonephritis and renal atrophy may develop. If only one kidney is obstructed, the other kidney may try to compensate by hypertrophy.

Partial obstruction may occur in the ureter or at the ureteropelvic junction (UPJ). If the pressure remains low or moderate, the kidney may continue to dilate with no noticeable loss of function. The risk of pyelonephritis is increased because of urinary stasis and reflux. If only one kidney is involved and the other kidney is functioning, the patient may be asymptomatic.

If both kidneys or only one functioning kidney is involved (e.g., if the patient has only one kidney), alterations in renal function (e.g., increased BUN or serum creatinine levels) are found. Progressive obstruction can lead to renal failure. Treatment requires location and relief of the blockage. This can include insertion of a tube (e.g., urethral or ureteral), surgical correction of the primary problem, or diversion of the urinary stream above the level of blockage.

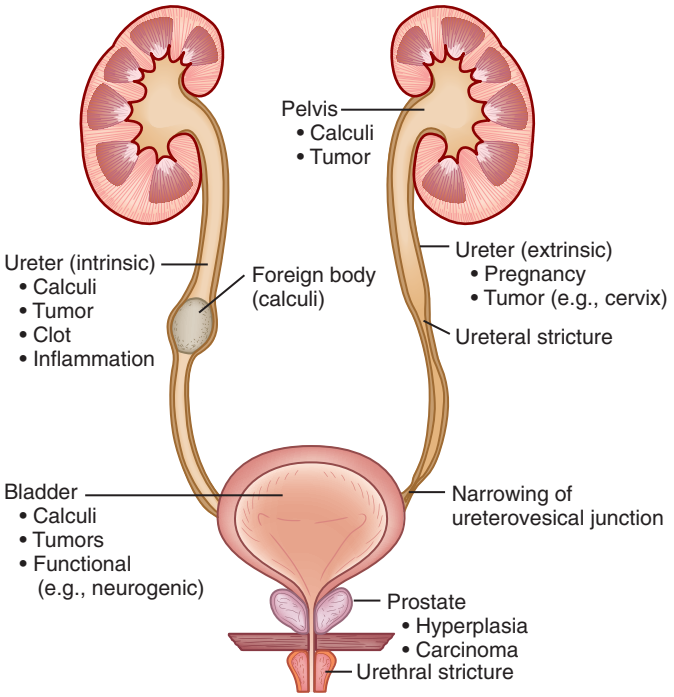

FIG. 46-3 Sites and causes of upper and lower urinary tract obstruction.

URINARY TRACT CALCULI

Each year an estimated 1 million to 2 million people in the United States have **nephrolithiasis** (kidney stone disease). In the United States the incidence of urinary stone disease is highest in the Southeast and Southwest, followed by the Midwest. Except for struvite (magnesium ammonium phosphate) stones associated with UTI, stone disorders are more common in men than in women. The majority of patients are between 20 and 55 years of age.[4]

Stone formation is more frequent in whites than in African Americans. The incidence is also higher in persons with a family history of stone formation. Stones can recur in up to 50% of patients. Stone formation occurs more often in the summer months, thus supporting the role of dehydration in this process.

Etiology and Pathophysiology

Many factors are involved in the incidence and type of stone formation, including metabolic, dietary, genetic, climatic, life-

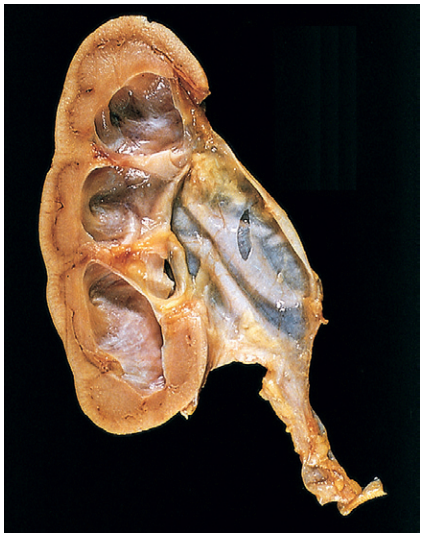

FIG. 46-4 Hydronephrosis of the kidney. Note the marked dilation of the pelvis and calyces and thinning of the renal parenchyma.

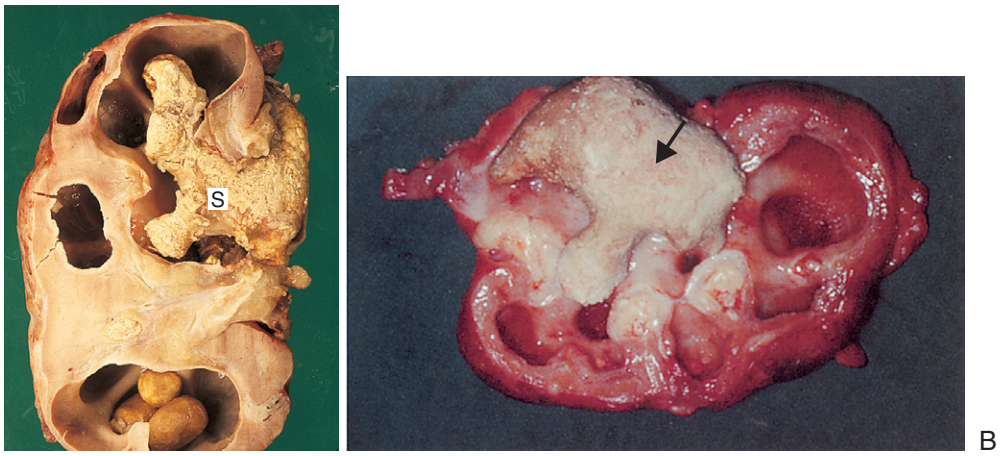

FIG. 46-5 **A,** Renal staghorn calculus. The renal pelvis is filled with a large calculus that is shaped to its contours, resembling the horns of a stag *(S)*. **B,** Imbedded staghorn calculus *(arrow)* in hydronephrotic, infected, nonfunctioning kidney.

style, and occupational influences (Table 46-10). Although many theories have been proposed, no single theory can account for stone formation in all cases. Crystals, when in a supersaturated concentration, can precipitate and unite to form a stone. Keeping urine dilute and free flowing reduces the risk of recurrent stone formation in many individuals. A mucoprotein is formed in the kidneys as a matrix for the stone. Urinary pH, solute load, and inhibitors in the urine affect the formation of stones. The higher the pH (alkaline), the less soluble are calcium and phosphate. The lower the pH (acidic), the less soluble are uric acid and cystine. When a substance is not very soluble in fluid, it is more likely to precipitate out of solution.[23]

GENDER DIFFERENCES

Urinary Tract Calculi

Men	Women
• Urinary calculi disorders (except for struvite stones) are more common in men.	• Struvite stones associated with urinary tract infection are more common in women than in men.

TABLE 46-10 RISK FACTORS FOR URINARY TRACT CALCULI

Metabolic
- Abnormalities that result in increased urine levels of calcium, oxaluric acid, uric acid, or citric acid

Climate
- Warm climates that cause increased fluid loss, low urine volume, and increased solute concentration in urine

Diet
- Large intake of dietary proteins that increases uric acid excretion
- Excessive amounts of tea or fruit juices that elevate urinary oxalate level
- Large intake of calcium and oxalate
- Low fluid intake that increases urinary concentration

Genetic Factors
- Family history of stone formation, cystinuria, gout, or renal acidosis
- Lifestyle
- Sedentary occupation, immobility

Other important factors in the development of stones include obstruction with urinary stasis and UTI with urea-splitting bacteria (e.g., *Proteus, Klebsiella, Pseudomonas,* and some species of staphylococci). These bacteria cause the urine to become alkaline and contribute to the formation of struvite stones. Infected stones, entrapped in the kidney (Fig. 46-5), may assume a staghorn configuration as the stone branches to occupy a large portion of the collecting system. These stones can lead to a renal infection, hydronephrosis, and loss of kidney function. Genetic factors may also contribute to urine stone formation. Cystinuria, an autosomal recessive disorder, is characterized by a markedly increased excretion of cystine.

Types of Urinary Calculi

The term **calculus** refers to the stone, and *lithiasis* refers to stone formation. The five major categories of stones are (1) calcium phosphate, (2) calcium oxalate, (3) uric acid, (4) cystine, and (5) struvite (magnesium ammonium phosphate) (Table 46-11). Although calcium stones are the most common, stone composition may be mixed. Calculi can be found in various locations in the urinary tract (see Figs. 46-3 and 46-5).

Clinical Manifestations

The first symptom of a kidney stone is usually severe pain that begins suddenly. Typically, a person feels a sharp pain in the flank area, back, or lower abdomen. People describe the pain as the most excruciating that a person can endure. *Renal colic* is the term used for the sharp, severe pain, which results from the stretching, dilation, and spasm of the ureter in response to the obstructing stone. Nausea and vomiting may occur due to the severe pain.[24]

Urinary stones cause clinical manifestations when they obstruct urinary flow. Common sites of obstruction are at the UPJ (where the renal pelvis narrows into the ureter) and at the ureterovesical junction (UVJ). The type of pain is determined by the location of the stone. If the stone is nonobstructing, pain may be absent. If the obstruction is in a calyx or at the UPJ, the patient may experience dull costovertebral flank pain or renal colic. Pain resulting from the passage of a calculus down the ureter is intense and colicky.

Patients with renal colic have a hard time being still. They go from walking to sitting to lying down, and then they

TABLE 46-11 TYPES OF URINARY TRACT CALCULI

Characteristics	Predisposing Factors	Treatment
Calcium Oxalate*		
Small, often possible to get trapped in ureter. More frequent in men than in women. *Incidence:* 35%-40%	Idiopathic hypercalciuria, hyperoxaluria, independent of urinary pH, family history	Increase hydration. Reduce dietary oxalate.† Give thiazide diuretics. Give cellulose phosphate to chelate calcium and prevent GI absorption. Give potassium citrate to maintain alkaline urine. Give cholestyramine to bind oxalate. Give calcium lactate to precipitate oxalate in GI tract. Reduce daily sodium intake.
Calcium Phosphate		
Mixed stones (typically), with struvite or oxalate stones. *Incidence:* 8%-10%	Alkaline urine, primary hyperparathyroidism	Treat underlying causes and other stones.
Struvite (Magnesium Ammonium Phosphate)		
Three or four times as common in women as men. Always associated with urinary tract infections. Large staghorn type (usually) (see Fig. 46-5). *Incidence:* 10%-15%	Urinary tract infections (usually *Proteus*)	Administer antimicrobial agents, acetohydroxamic acid. Use surgical intervention to remove stone. Take measures to acidify urine.
Uric Acid		
Predominant in men, high incidence in Jewish men. *Incidence:* 5%-8%	Gout, acidic urine, inherited condition	Reduce urinary concentration of uric acid. Alkalinize urine with potassium citrate. Administer allopurinol. Reduce dietary purines.†
Cystine		
Genetic autosomal recessive defect. Defective absorption of cystine in GI tract and kidney, excess concentrations causing stone formation. *Incidence:* 1%-2%	Acidic urine	Increase hydration. Give α-penicillamine and tiopronin to prevent cystine crystallization. Give potassium citrate to maintain alkaline urine.

*Calcium stones can exist as calcium oxalate, calcium phosphate, or a mixture of both. Calcium stones account for the majority of all stones.
†See Table 43-12: Causes of Peritonitis.

repeat the process. Some people refer to this as the *kidney stone dance.*

The patient may be in mild shock with cool, moist skin. As a stone nears the UVJ, pain moves around toward the abdomen and down toward the lower quadrant. Men may experience testicular pain, whereas women may complain of labial pain. Both men and women may experience pain in the groin. The patient may also have manifestations of UTI with dysuria, fever, and chills.

Diagnostic Studies

Noncontrast spiral CT, also called a CT/KUB (kidneys, ureters, bladder), is the diagnostic study commonly used in patients with renal colic. It is quick and noninvasive and requires no IV contrast. In some situations, ultrasound and IVP are used. A complete urinalysis helps confirm the diagnosis of a urinary stone by assessing for hematuria, crystalluria, and urinary pH.

Retrieval and analysis of the stones are important in the diagnosis of the underlying problem contributing to stone formation. The patient's serum calcium, phosphorus, sodium, potassium, bicarbonate, uric acid, BUN, and creatinine levels are also measured. A careful history should include any previous episodes of stone formation, prescribed and OTC medications, dietary supplements, and family history of urinary calculi. Measurement of urine pH is useful in the diagnosis of struvite stones and renal tubular acidosis (tendency to alkaline or high pH) and uric acid stones (tendency to acidic or low pH). Patients who are recurrent stone formers should undergo a 24-hour urinary measurement of calcium, phosphorus, magnesium, sodium, oxalate, citrate, sulfate, potassium, uric acid, and total volume.

Collaborative Care

Evaluation and management of a patient with renal calculi consist of two concurrent approaches. The first approach is directed toward management of the acute attack by treating the pain, infection, and/or obstruction. Administer opioids to relieve renal colic pain. Most stones are 4 mm or less in size and will probably pass spontaneously. However, it may take weeks for a stone to pass.

Tamsulosin (Flomax) or terazosin (Hytrin), α-adrenergic blockers that relax the smooth muscle in the ureter, can be used to facilitate stone passage. These drugs are also used to relax the muscle tissue in the prostate in men with BPH.

The second approach is directed toward evaluation of the cause of the stone formation and the prevention of further stone development. Obtain information from the patient, including a family history of stone formation; geographic residence; nutritional assessment, including the intake of vitamins A and D; activity pattern (active or sedentary); history of prolonged illness with immobilization or dehydration; and any history of disease or surgery involving the GI or genitourinary tract.

Therapy for active stone formers requires a comprehensive management approach, with the primary emphasis on teaching. Adequate hydration, dietary sodium restrictions, dietary changes, and drugs are employed to minimize urinary stone formation (see Table 46-11). Various drugs are prescribed, depending on the specific problem underlying the stone formation. These drugs prevent stone formation in various ways, including altering urine pH, preventing excessive urinary excretion of a substance, or correcting a primary disease (e.g., hyperparathyroidism).

Treatment of struvite stones requires control of infection. This may be difficult if the stone remains in place. In addition

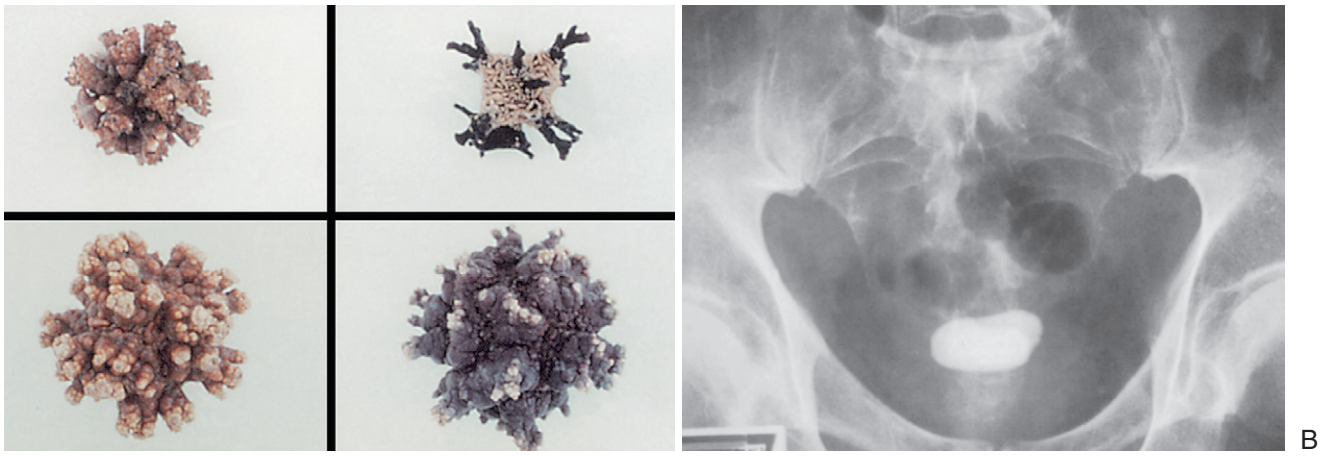

FIG. 46-6 **A,** Calcium oxalate stones. **B,** Plain abdominal x-ray showing large bladder calculus.

to antibiotics, acetohydroxamic acid may be used to treat kidney infections that result in the continual formation of struvite stones. Acetohydroxamic acid inhibits the chemical action caused by the persistent bacteria and thus retards struvite stone formation. The stone may have to be removed surgically if the infection cannot be controlled.

Indications for endourologic, lithotripsy, or open surgical stone removal include the following: (1) stones too large for spontaneous passage (usually greater than 7 mm); (2) stones associated with bacteriuria or symptomatic infection; (3) stones causing impaired renal function; (4) stones causing persistent pain, nausea, or paralytic ileus; (5) inability of patient to be treated medically; and (6) patient with only one kidney.

Endourologic Procedures. If the stone is located in the bladder, a cystoscopy is done to remove small stones. For large stones (Fig. 46-6), a *cystolitholapaxy* is done. In this procedure, large stones are broken up with an instrument called a lithotrite (stone crusher). The bladder is then irrigated and the crushed stones washed out. A *cystoscopic lithotripsy* uses an ultrasonic lithotrite to pulverize (break up) stones. Complications associated with these cystoscopic procedures include hemorrhage, retained stone fragments, and infection.

Flexible *ureteroscopes,* inserted via a cystoscope, can be used to remove stones from the renal pelvis and upper urinary tract. Ultrasonic, laser, or electrohydraulic lithotripsy may be used in conjunction with the ureteroscope to pulverize the stone.

In *percutaneous nephrolithotomy,* a nephroscope is inserted into the kidney pelvis through a track (using a sheath) in the skin. The track is created in the patient's back. The kidney stones can be fragmented using ultrasound, electrohydraulic, or laser lithotripsy. The stone fragments are removed, and the pelvis is irrigated. A percutaneous nephrostomy tube is usually left in place to make sure that the ureter is not obstructed. Complications include bleeding, injury to adjacent structures, and infection.

Lithotripsy. **Lithotripsy** is a procedure used to eliminate calculi from the urinary tract. Lithotripsy techniques include (1) laser lithotripsy, (2) extracorporeal shock-wave lithotripsy (ESWL), (3) percutaneous ultrasonic lithotripsy, and (4) electrohydraulic lithotripsy. *Laser lithotripsy* is used to fragment ureteral and large bladder stones (bladder stones are described above). To access ureteral stones, a ureteroscope is used to get close to the stone. A small fiber is inserted up the endoscope so that the tip (which emits the laser energy) can come in contact with the stone. A holmium laser in direct contact with the stone is commonly used. The intense energy breaks the stone into small pieces, which can be extracted or flushed out. Because of the type of laser energy, no other tissue is affected. This minimally invasive treatment usually requires general anesthesia.[25]

In *extracorporeal shock-wave lithotripsy (ESWL),* a noninvasive procedure, the patient is anesthetized (spinal or general) to ensure that he or she maintains the same position during the procedure. Fluoroscopy or ultrasound is used to focus the lithotripter on the affected kidney, and a high-voltage spark generator produces high-energy acoustic shock waves that shatter the stone without damaging the surrounding tissues. The stone is broken into fine sand *(steinstrasse)* and excreted in the urine.

In *percutaneous ultrasonic lithotripsy* an ultrasonic probe is placed in the renal pelvis via a percutaneous nephroscope inserted through a small incision in the flank, and is then positioned against the stone. The patient is given general or spinal anesthesia for this procedure. The probe produces ultrasonic waves, which break the stone into sandlike particles.

In *electrohydraulic lithotripsy* the probe is positioned directly on a stone, but it breaks the stone into small fragments that are removed by forceps or by suction. A continuous saline irrigation flushes out the stone particles, and all of the outflow drainage is strained so that the particles can be analyzed. The calculi can also be removed by basket extraction. Complications are rare but they include hemorrhage, sepsis, and abscess formation. Postoperatively, the patient usually complains of moderate to severe colicky pain. The first few times that the patient urinates, the urine is bright red. As the bleeding subsides, the urine becomes dark red or a smoky color. Antibiotics are usually administered after the procedure to reduce the risk of infection.

Hematuria is common after lithotripsy procedures. A self-retaining ureteral stent is often placed after the procedure to facilitate passage of sand (shattered stone) and prevent sand buildup within the ureter, which might lead to obstruction. The stent is typically removed within 2 weeks following lithotripsy. If a stone is large or positioned in the mid or distal ureter, additional treatment, such as surgery, may be necessary.

Surgical Therapy. A small group of patients require open surgical procedures. The primary indications for surgery include pain, infection, and obstruction. The type of open surgery performed depends on the location of the stone. A *nephrolithotomy* is an incision into the kidney to remove a stone. A *pyelolithot-*

TABLE 46-12 NUTRITIONAL THERAPY

Urinary Tract Calculi

Depending on the type of calculi, modify the diet to decrease foods that are high in the substance that is the cause of the calculi. Listed below are foods that are moderate or high in purine, calcium, or oxalate content.

Purine*

High: Sardines, herring, mussels, liver, kidney, goose, venison, meat soups, sweetbreads

Moderate: Chicken, salmon, crab, veal, mutton, bacon, pork, beef, ham

Calcium

High: Milk, cheese, ice cream, yogurt, sauces containing milk; all beans (except green beans), lentils; fish with fine bones (e.g., sardines, kippers, herring, salmon); dried fruits, nuts; Ovaltine, chocolate, cocoa

Oxalate

High: Dark roughage, spinach, rhubarb, asparagus, cabbage, tomatoes, beets, nuts, celery, parsley, runner beans; chocolate, cocoa, instant coffee, Ovaltine, tea; Worcestershire sauce

*Uric acid is a waste product from purine in food.

omy is an incision into the renal pelvis for stone removal. If the stone is located within the ureter, a *ureterolithotomy* is performed. A *cystotomy* may be indicated for bladder calculi. For open surgery on the kidney or ureter, a flank incision directly below the diaphragm and across the side is usually preferred. The most common complications after surgical procedures for stone removal are related to hemorrhage.

Nutritional Therapy. To manage an obstructing stone, have the patient drink adequate fluids to avoid dehydration. Forcing excessive fluids is not advised, since this has not proved effective in facilitating spontaneous passage (excretion) of stones via the urine. Forcing fluids may also increase the pain or precipitate the development of renal colic.

After an episode of urolithiasis, encourage a high fluid intake (approximately 3 L/day) to produce a urine output of at least 2 L/day. High urine output prevents supersaturation of minerals (i.e., dilutes the concentration of urine) and promotes excretion of minerals within the urine, thus preventing stone formation. Increasing the fluid intake is particularly important for patients at risk for dehydration, including those who (1) are active in sports, (2) live in a dry climate, (3) perform physical exercise, (4) have a family history of stone formation, or (5) work outside or in an occupation that requires a great deal of physical activity. Water is the preferred fluid. Limit consumption of colas, coffee, and tea because high intake of these beverages tends to increase the risk of recurring urinary calculi.

A low-sodium diet is recommended, since high-sodium intake increases calcium excretion in the urine. Foods high in calcium, oxalate, and purines are presented in Table 46-12.

NURSING MANAGEMENT URINARY TRACT CALCULI

NURSING ASSESSMENT

Subjective and objective data that should be obtained from a patient with urinary tract calculi are presented in Table 46-13.

TABLE 46-13 NURSING ASSESSMENT

Urinary Tract Calculi

Subjective Data

Important Health Information

Past health history: Recent or chronic UTI; bed rest; immobilization; previous urinary tract stones, obstruction, or kidney disease with urinary stasis; gout; benign prostatic hyperplasia (BPH); hyperparathyroidism, chronic diarrhea

Medications: Prior use of medication for prevention of stones or treatment of UTI; allopurinol, analgesics, loop diuretics

Surgery or other treatments: External urinary diversion, long-term indwelling urinary catheter

Functional Health Patterns

Health perception–health management: Family history of renal calculi; sedentary lifestyle

Nutritional-metabolic: Nausea, vomiting; dietary intake of purines, excessive calcium ingestion, salt excess, oxalates, phosphates; low fluid intake; chills

Elimination: Decreased urine output, urinary urgency, frequency, feeling of bladder fullness

Cognitive-perceptual: Acute, severe, colicky pain in flank, back, abdomen, groin, or genitalia; burning on urination, dysuria; anxiety

Objective Data

General

Guarding, back pain, fever, dehydration

Integumentary

Warm, flushed skin or pallor with cool, moist skin (mild shock)

Gastrointestinal

Abdominal distention, absence of bowel sounds

Urinary

Oliguria, hematuria, tenderness on palpation of renal areas, passage of stone or stones

Possible Diagnostic Findings

↑ BUN and serum creatinine levels; RBCs, WBCs, pyuria, crystals, casts, minerals, bacteria on urinalysis; ↑ uric acid, calcium, phosphorus, oxalate, or cystine values on 24-hr urine sample; calculi or anatomic changes on IVP or KUB x-ray; direct visualization of obstruction on cystoureteroscopy

IVP, Intravenous pyelogram; *KUB,* kidneys, ureters, bladder; *UTI,* urinary tract infection.

NURSING DIAGNOSES

Nursing diagnoses for the patient with urinary tract calculi include, but are not limited to, the following:

- Impaired urinary elimination *related to* trauma or obstruction of ureters or urethra
- Acute pain *related to* effects of stones and inadequate pain control or comfort measures
- Deficient knowledge *related to* unfamiliarity with information resources and lack of experience with urinary stones

Additional information on nursing diagnoses for the patient with urinary tract calculi is presented in eNursing Care Plan 46-2 (on the website for this chapter).

PLANNING

The overall goals are that the patient with urinary tract calculi will have (1) relief of pain, (2) no urinary tract obstruction, and (3) knowledge of ways to prevent recurrence of stones.

NURSING IMPLEMENTATION

Most people who have had urinary stones can lower their risk of recurrence by changing their lifestyle and dietary habits. Adequate fluid intake is important to produce a urine output of approximately 2 L/day. Consult with the health care provider about recommendations for fluid intake in a given patient. The moderately active, ambulatory person should drink about 3 L/day. Fluid intake needs to be higher in the active patient who works outdoors or who regularly engages in athletic activities. In contrast, fluid intake is less for the sedentary or immobile person. Preventive measures related to the person who is on bed rest or is relatively immobile for a prolonged time include maintaining an adequate fluid intake, turning the patient every 2 hours, and helping the patient sit or stand, if possible, to maximize urinary flow.

Additional preventive measures focus on reducing metabolic or secondary risk factors. For example, dietary restriction of purines may be helpful for the patient at risk for developing uric acid stones. Teach the patient the dosage, scheduling, and potential side effects of drugs used to reduce the risk of stone formation (see Table 46-11). Some patients may be taught to self-monitor urinary pH or urine output.

Pain management and patient comfort are primary nursing responsibilities when managing an obstructing stone and renal colic (see eNursing Care Plan 46-2). To ensure that any spontaneously passed stones are retrieved, strain all urine voided by the patient using a gauze or a urine strainer. Encourage ambulation to promote movement of the stone from the upper to the lower urinary tract. To ensure safety, tell the patient not to walk unattended while experiencing acute renal colic, particularly if opioid analgesics are being given.

EVALUATION

The expected outcomes are that the patient with urinary calculi will

- Maintain free flow of urine with minimal hematuria
- Report satisfactory pain relief
- Verbalize understanding of disease process and measures to prevent recurrence

Additional information on expected outcomes for the patient with urinary calculi is presented in eNursing Care Plan 46-2 (on the website for this chapter).

STRICTURES

A **stricture** is a narrowing of the lumen of the ureter or urethra.

Ureteral Strictures

Ureteral strictures can affect the entire length of the ureter, from the UPJ to the UVJ. These strictures are usually an unintended result of surgical intervention or secondary to adhesions or scar formation, or they may be due to extrinsic factors such as large tumors in the peritoneal cavity. Depending on its severity, ureteral obstruction can threaten the function of the kidney.

Clinical manifestations of a ureteral stricture include mild to moderate colic. This pain may be moderate to severe in intensity if the patient consumes a large volume of fluids (such as alcohol) over a brief period. Infection is unusual unless a calculus or foreign object such as a stent or nephrostomy tube is present.

The discomfort and obstruction of a ureteral stricture may be temporarily bypassed by placing a stent using endoscopy or by diverting urinary flow via a nephrostomy tube inserted into the renal pelvis of the affected kidney. Definitive correction requires dilation with a balloon or catheter. If the stricture is severe or recurs after initial balloon or catheter dilation, it is surgically incised using an endoscopic procedure *(endoureterotomy)*. In selected cases an open surgical approach may be required to excise the stenotic area and reanastomose the ureter to the contralateral ureter *(ureteroureterostomy)* or to the renal pelvis. Alternatively, distal ureteral strictures may be treated by a *ureteroneocystostomy* (reimplantation of the ureter into the bladder wall).

Urethral Strictures

A *urethral stricture* is the result of fibrosis or inflammation of the urethral lumen. Causes of urethral strictures include trauma, urethritis (particularly after gonococcal infection), surgical intervention or repeated catheterizations (iatrogenic), or a congenital defect of the urethra. Once the process of inflammation and fibrosis begins, the lumen of the urethra narrows, and its compliance (ability to close or open in response to bladder filling or micturition) is compromised. Meatal stenosis, a narrowing of the urethral opening, is also common.

Clinical manifestations associated with a urethral stricture include a diminished force of the urinary stream, straining to void, sprayed stream, postvoid dribbling, or a split urine stream. The patient may report feelings of incomplete bladder emptying with urinary frequency and nocturia. Moderate to severe obstruction of the bladder outlet may lead to acute urinary retention. The patient may report a history of urethritis, difficulty with insertion of a urinary catheter, or trauma involving the penis or the perineum. However, many patients are unable to recall any such events, thus leading to a diagnosis of an idiopathic stricture. A history of UTI is common, particularly if the stricture involves the distal urethra. Retrograde urethrography (RUG) and VCUG are used to identify stricture length, location, and caliber.

Initial management of a stricture is focused on dilation. A metal instrument (urethral sound) may be placed, or a series of progressively large stents (filiforms and followers) can be placed into the urethra to expand its lumen in a stepwise fashion. Although this process is initially successful, stenosis frequently recurs. Recurrences may be managed by teaching the patient to repeatedly dilate the urethra by self-catheterization using a soft (coudé-tip, red rubber) catheter every few days. Alternatively, an endoscopic or open surgical procedure *(urethroplasty)* may be a more definitive therapy for an obstructive urethral stricture. Shorter strictures may be treated by resection of the fibrotic area followed by reanastomosis of the urethra. Longer strictures may require the use of a skin flap as a substitute urethral segment.

RENAL TRAUMA

Renal trauma can be blunt or penetrating. *Blunt trauma* is the most common cause. Injury to the kidney should be considered in sports injuries, motor vehicle collisions, and falls. Renal trauma is especially likely when the patient injures the abdomen, flank, or back. *Penetrating injuries* may result from violent encounters (e.g., gunshot or stabbing incidents). The majority of incidents occur in men younger than 30 years of age.

Clinical findings include a history of trauma to the area of the kidneys. Gross or microscopic hematuria may be present.

Diagnostic studies include urinalysis, ultrasound, CT, or MRI evaluation. Renal arteriography may also be used. Both the injured kidney and the uninvolved kidney should be evaluated. The severity of renal trauma depends on the extent of the injury. Treatments range from bed rest, fluids, and analgesia to exploratory surgery and repair or nephrectomy.

Nursing interventions depend on the type of renal trauma and the extent of any associated injuries. Interventions related to renal trauma include the following: (1) assess the cardiovascular status and monitor for shock, especially in a penetrating injury; (2) ensure adequate fluid intake and monitor intake and output; (3) provide for pain relief and comfort measures; and (4) assess for hematuria and myoglobinuria.

RENAL VASCULAR PROBLEMS

Vascular problems involving the kidney include (1) nephrosclerosis, (2) renal artery stenosis, and (3) renal vein thrombosis.

NEPHROSCLEROSIS

Nephrosclerosis is sclerosis of the small arteries and arterioles of the kidney. The decreased blood flow results in ischemia and necrosis of parts of the kidney. *Benign nephrosclerosis,* which usually occurs in adults 30 to 50 years of age, is caused by vascular changes resulting from hypertension and from the atherosclerosis process. Atherosclerotic vascular changes account for most of the loss of renal function associated with aging. The degree of nephrosclerosis is directly related to the severity of hypertension. In the early stages, the patient with benign nephrosclerosis may have normal renal function, with the only detectable abnormality being hypertension.

Accelerated nephrosclerosis (malignant nephrosclerosis) is associated with malignant hypertension, which is characterized by a sharp increase in BP with a diastolic pressure greater than 130 mm Hg. The patient is usually a young adult, with a male-to-female predominance of 2:1. Renal insufficiency progresses rapidly.

Treatment for benign nephrosclerosis is the same as that for essential hypertension (see Chapter 33). Malignant nephrosclerosis is treated with aggressive antihypertensive therapy (see Chapter 33). The availability and use of antihypertensive drugs have improved the prognosis for patients with benign and malignant nephrosclerosis. Kidney disease, and subsequent renal failure, is a major complication of hypertension. The prognosis for a patient with untreated or refractive malignant hypertension is poor, with the major cause of death related to renal failure.

RENAL ARTERY STENOSIS

Renal artery stenosis is a partial occlusion of one or both renal arteries and their major branches. It can be due to atherosclerotic narrowing or fibromuscular hyperplasia. Renal artery stenosis, which accounts for 1% to 2% of all cases of hypertension, is a cause of secondary hypertension.

When hypertension develops rather abruptly, renal artery stenosis should be considered as a possible cause, especially in patients under 30 or over 50 years of age and in patients with no family history of hypertension. This contrasts with the age distribution for primary hypertension, which is 30 to 50 years of age. Diagnostic tests used to assess for renal artery stenosis include a renal ultrasound, CT scan, MRI scan, and renal arteriogram (the best diagnostic tool).

The goals of therapy are to control the BP and restore perfusion to the kidney. Percutaneous transluminal renal angioplasty is the procedure of choice, especially in older patients who are poor surgical risks. Surgical revascularization of the kidney is indicated when decreased blood flow causes renal ischemia or when renovascular hypertension is present. Revascularization of the kidney may result in the patient becoming normotensive. The surgical procedure usually involves anastomoses between the kidney and another major artery, usually the splenic artery or aorta. In selected cases of unilateral renal involvement, unilateral nephrectomy may be indicated.

RENAL VEIN THROMBOSIS

Renal vein thrombosis may occur unilaterally or bilaterally. Causes include trauma, extrinsic compression (e.g., tumor, aortic aneurysm), renal cell cancer, pregnancy, contraceptive use, and nephrotic syndrome.

The patient has symptoms of flank pain, hematuria, or fever or has nephrotic syndrome. Anticoagulation (e.g., heparin, warfarin [Coumadin]) is important to treat the high incidence of pulmonary emboli. Corticosteroids may be used for the patient with nephrotic syndrome. Surgical thrombectomy may be performed instead of or along with anticoagulation.

HEREDITARY KIDNEY DISEASES

Hereditary kidney (or renal) diseases involve developmental abnormalities of the renal parenchyma. Most inherited structural abnormalities are cystic. However, cysts may also develop as a result of obstructive uropathies, metabolic problems, or neurologic diseases. Cysts may be evaluated to rule out tumors.

POLYCYSTIC KIDNEY DISEASE

Polycystic kidney disease (PKD) is the most common life-threatening genetic disease in the world, affecting 600,000 people in the United States. PKD accounts for 10% to 15% of chronic kidney disease.[26]

Genetic Link

PKD has two hereditary forms: it may be manifested in childhood or adulthood. The childhood form of PKD is a rare autosomal recessive disorder that is often rapidly progressive (see the Genetics in Clinical Practice box). The adult form of PKD is an autosomal dominant disorder (see Figs. 13-4 and 13-5). If one parent has the disease, there is a 50% chance that the disease will pass to the child.

Adult PKD is latent for many years and is usually manifested between 30 and 40 years of age. It involves both kidneys and occurs in both men and women. The cortex and the medulla are filled with large, thin-walled cysts that are several millimeters to several centimeters in diameter (Fig. 46-7). The cysts enlarge and destroy surrounding tissue by compression. The cysts are filled with fluid and may contain blood or pus. PKD kidneys examined during autopsy appear as if they are filled with golf balls.

Early in the disease patients are generally asymptomatic. Symptoms appear when the cysts begin to enlarge. Often the first manifestations of PKD are hypertension; hematuria (from

GENETICS IN CLINICAL PRACTICE

Polycystic Kidney Disease (PKD)

	Adult	Child
Genetic basis	• Autosomal dominant	• Autosomal recessive
Incidence	• 1 in 400-1000	• 1 in 10,000-20,000
Gene location	• *PKD1* gene on chromosome 16 and *PKD2* gene on chromosome 4 • Genes code for polycystins (proteins that promote normal kidney development and function) • Mutations in genes lead to formation of thousands of cysts that disrupt the normal function of kidneys and other organs	• Polycystic kidney and hepatic disease *(PKHD1)* gene on chromosome 6 • Gene codes for fibrocystin • Mutations in gene leads to cyst formation
Genetic testing	• DNA testing available	• DNA testing available*
Age of onset	• Ages 30-40	• Infancy or childhood
Clinical implications	• Multisystem involvement • Systemic hypertension occurs in 60%-80% of patients • Increased risk for cerebral aneurysms • Families at risk should be screened	• Up to 30%-50% of affected newborns die shortly after birth • If infant survives the newborn period, chances of survival are good, but about one third need dialysis or transplantation by age 10 yr

*Genetic testing is also available on fertilized embryos before implantation. This allows embryos free of the disorder to be placed into the uterus.

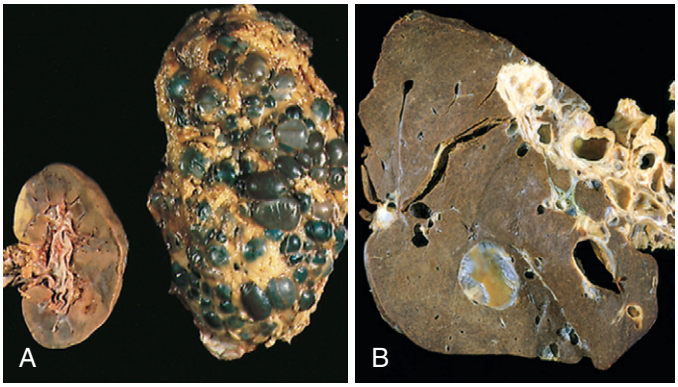

FIG. 46-7 **A,** Comparison of polycystic kidney with normal kidney. **B,** Cysts in the liver.

rupture of cysts); or a feeling of heaviness in the back, side, or abdomen. However, the first manifestations can also be a UTI or urinary calculi. Chronic pain is one of the most common problems experienced by individuals with PKD. The pain can be constant and severe. Bilateral, enlarged kidneys are often palpable on physical examination. Many people have no symptoms, and the disease is not diagnosed.

PKD can also affect the liver (liver cysts [see Fig. 46-7]), heart (abnormal heart valves), blood vessels (aneurysms), and intestines (diverticulosis). The most serious complication is a cerebral aneurysm, which can rupture.

Diagnosis is based on clinical manifestations, family history, ultrasound (best screening measure), or CT scan. The disease usually progresses from loss of kidney function to ESKD by age 60 in 50% of patients.[27]

NURSING AND COLLABORATIVE MANAGEMENT POLYCYSTIC KIDNEY DISEASE

There is no specific treatment for PKD. A major aim of treatment is to prevent or treat infections of the urinary tract. Nephrectomy may be necessary if pain, bleeding, or infection becomes a chronic, serious problem. Dialysis and kidney transplant may be needed to treat ESKD (see Chapter 47).

When the patient begins to experience progressive renal failure, the interventions depend on the remaining renal function. Nursing measures are those used for management of ESKD. They include diet modification, fluid restriction, drugs (e.g., antihypertensives), and assistance for the patient and family in coping with the chronic disease process and financial concerns.

The patient who has adult PKD often has children by the time the disease is diagnosed. The patient needs appropriate counseling regarding plans for having more children. In addition, genetic counseling should be provided for the children.

MEDULLARY CYSTIC DISEASE

Medullary cystic disease is a hereditary disorder that occurs in two forms. The *autosomal recessive form* is associated with renal failure before age 20. The *autosomal dominant form* is associated with renal failure after age 20.

Most cysts are located in the medulla. The kidneys are asymmetric in shape and are significantly scarred. Defects in the kidneys' concentrating ability result in polyuria. Other clinical manifestations include hypertension, progressive renal failure, severe anemia, and metabolic acidosis. Genetic counseling may be helpful in family planning. Treatment measures are those related to ESKD (see Chapter 47).

ALPORT SYNDROME

Alport syndrome, also known as *chronic hereditary nephritis,* has two forms: (1) classic Alport syndrome, which is inherited as a sex-linked disorder with hematuria, sensorineural deafness, and deformities of the anterior surface of the lens; and (2) nonclassic Alport syndrome, which is inherited as an autosomal disorder that causes hematuria but not deafness or lens deformities.

Men are affected earlier and more severely than women. The disease is often diagnosed in the first decade of life. The basic defect is a mutation in a gene for collagen that results in altered synthesis of the GBM. Most commonly the patient has hematuria and progressive uremia. Treatment is supportive. Corticosteroids and cytotoxic drugs are not effective. The disease does not recur after kidney transplantation.

URINARY TRACT TUMORS

KIDNEY CANCER

Kidney cancers arise from the cortex or pelvis (and calyces). Tumors from these areas may be benign or malignant. However, malignant tumors are more common. In the United States, about 65,000 new cases of kidney cancer are diagnosed each year and about 13,570 people die from kidney cancer. The incidence of kidney cancer is increasing, but the reason for this is not known.[28]

Renal cell carcinoma (adenocarcinoma) is the most common type of kidney cancer (Fig. 46-8). This type of tumor occurs twice as often in men as in women and is typically discovered when the person is 50 to 70 years of age. Cigarette smoking is the most significant risk factor for the development of renal cell carcinoma. An increased incidence has also been found in first-degree relatives of people who have or had renal cell carcinoma. Other risk factors include obesity; hypertension; and exposure to asbestos, cadmium, and gasoline. Risk for kidney cancer is also increased in individuals who have acquired cystic disease of the kidney associated with ESKD (see Chapter 47).[29]

Clinical Manifestations and Diagnostic Studies

Kidney cancer has no characteristic early symptoms, so many patients go undiagnosed until the disease has significantly progressed. Kidney tumors can cause symptoms by compressing, stretching, or invading structures near or within the kidney. The most common presenting manifestations are hematuria, flank pain, and a palpable mass in the flank or abdomen. Other clinical manifestations include weight loss, fever, hypertension, and anemia.

About 30% of patients have metastasis at the time of diagnosis. Local extension of kidney cancer into the renal vein and vena cava is common (see Fig. 46-8). The most common sites of metastases include lungs, liver, and long bones. Many kidney cancers are diagnosed as incidental findings on imaging studies used to evaluate symptoms for unrelated conditions.

CT scan is commonly used in the diagnosis and can detect small kidney tumors. Ultrasound examinations have improved the ability to differentiate between a solid mass tumor and a cyst. This is significant because the majority of masses detected on imaging are cysts. Angiography, biopsy, and MRI are also used in the diagnosis of renal tumors. Radionuclide isotope scanning is used to detect metastases.

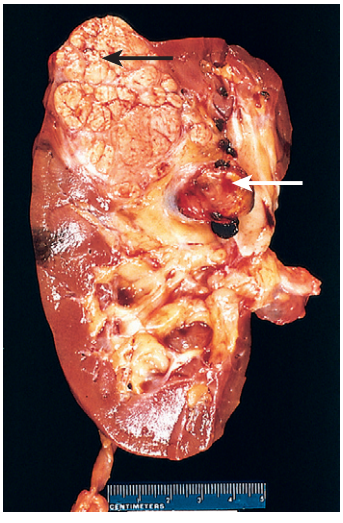

FIG. 46-8 Cross section of kidney with renal cell carcinoma. The carcinoma *(black arrow)* is on the pole of the kidney. Note that the renal vein is involved and thrombosed *(white arrow)*.

NURSING AND COLLABORATIVE MANAGEMENT KIDNEY CANCER

Preventive measures, such as quitting smoking, maintaining a healthy weight, controlling BP, and reducing or avoiding exposure to toxins, can help reduce the incidence of kidney cancer. Patients in high-risk groups should be aware of their increased risk for kidney cancer. Teach them about early symptoms (e.g., hematuria, hypertension). A cure for kidney cancer is possible when it is detected early and treated.

Collaborative care of the patient with kidney cancer is presented in Table 46-14. Staging of renal carcinoma provides a basis for determining treatment options. A detailed listing of staging is presented in eTable 46-1 (on the website for this chapter). The following is a simple description of staging of kidney cancer:

Stage I: The tumor can be up to 7 cm in diameter but is confined to the kidney.

Stage II: The tumor is larger than a stage I tumor, but is still confined to the kidney.

Stage III: The tumor extends beyond the kidney to the surrounding tissue and may also have spread to a nearby lymph node.

Stage IV: Cancer spreads outside the kidney to multiple lymph nodes or to distant parts of the body, such as bones, brain, liver, or lung.

The treatment of choice for some renal cancers is a partial nephrectomy (for smaller tumors) or a radical nephrectomy (for larger tumors). Radical nephrectomy involves removal of the kidney, adrenal gland, surrounding fascia, part of the ureter, and draining lymph nodes. Nephrectomy can be performed by a conventional (open) approach or laparoscopically (see discussion of nephrectomy on p. 1095). Radiation therapy is used palliatively in inoperable cases and when there is metastasis to bone or lungs.

Other treatment options include cryoablation (freezing technique) and radiofrequency ablation (destroying tumor by using radiofrequency heat). These procedures can be used when surgery is not an option (e.g., patient has co-morbid conditions).

Chemotherapy is used as a treatment in metastatic disease. These drugs include 5-fluorouracil (5-FU), floxuridine (FUDR),

TABLE 46-14 COLLABORATIVE CARE

and gemcitabine (Gemzar). However, renal cell carcinoma is refractory to most chemotherapy drugs.

Biologic therapy, including α-interferon and interleukin-2 (IL-2), is another treatment in metastatic disease. (The use of α-interferon and IL-2 is discussed in Chapter 16.)

Targeted therapy is the preferred treatment for metastatic kidney cancer. Kinase inhibitors, one class of targeted therapies, block certain proteins (kinases) that play a role in tumor growth and cancer progression. Kinase inhibitors include sunitinib (Sutent), sorafenib (Nexavar), and axitinib (Inlyta). Bevacizumab (Avastin) and pazopanib (Votrient) inhibit the formation of new blood vessel growth to the tumor. Temsirolimus (Torisel) and everolimus (Afinitor) inhibit a specific protein known as the mammalian target of rapamycin (mTOR). These drugs are presented in Table 16-13, and the mechanisms of action are shown in Fig. 16-16.

The diagnosis of cancer is a shock. In kidney cancer the disease can already be metastasized by the time a person is diagnosed. (The nursing care of the patient with cancer is discussed in Chapter 16.)

BLADDER CANCER

About 73,000 new cases of bladder cancer are diagnosed annually, and about 15,000 deaths related to bladder cancer occur every year.[28] Bladder cancer accounts for nearly 1 in every 20 cancers diagnosed in the United States. The most frequent malignant tumor of the urinary tract is transitional cell carcinoma of the bladder. Most bladder tumors are papillomatous growths within the bladder (Fig. 46-9).

Cancer of the bladder is most common between ages 60 and 70 years and is at least three times more common in men than in women. Risk factors for bladder cancer include cigarette smoking, exposure to dyes used in the rubber and other industries, and chronic abuse of phenacetin-containing analgesics. Phenacetin, once a popular analgesic, has been removed from the market. Women treated with radiation for cervical cancer, patients who received cyclophosphamide, and patients who take the diabetes drug pioglitazone (Actos) also have an increased risk for bladder cancer.

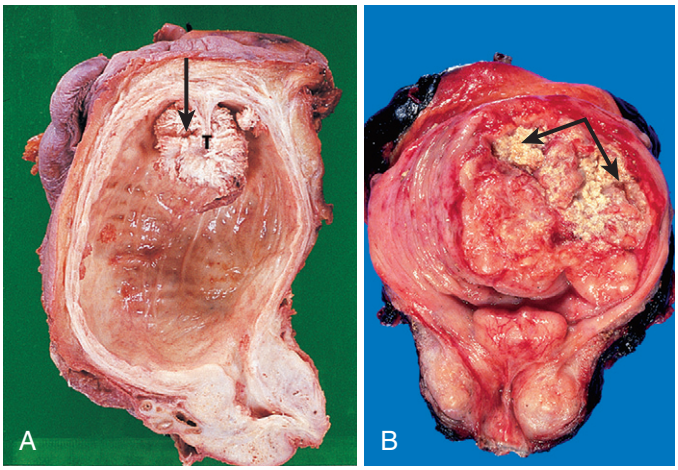

FIG. 46-9 **A,** Papillary transitional cell carcinoma *(T)* seen arising from the dome of the bladder as a cauliflower-like lesion *(arrow).* **B,** Opened bladder showing bladder cancer at an advanced stage. Yellow areas represent ulcerations and necrosis *(arrows).*

Individuals with chronic, recurrent renal calculi (often bladder) and chronic lower UTIs have an increased risk of squamous cell cancer of the bladder. Patients who have indwelling catheters for long periods are also at an increased risk to develop bladder cancer.

Clinical Manifestations and Diagnostic Studies

Microscopic or gross, painless hematuria (chronic or intermittent) is the most common clinical manifestation of bladder cancer. Bladder irritability with dysuria, frequency, and urgency may also occur. When cancer is suspected, obtain urine specimens to identify any neoplastic or atypical cells. Exfoliated cells from the bladder's epithelial surface can be detected in voided specimens. Other urine tests assess for specific factors associated with bladder cancer, such as bladder tumor antigens.

Bladder cancers can be detected using CT, ultrasound, or MRI. The presence of cancer is confirmed by cystoscopy and biopsy. Cystoscopy with biopsy is the most reliable test for detecting bladder tumors.

NURSING AND COLLABORATIVE MANAGEMENT BLADDER CANCER

The majority of bladder cancers are diagnosed at an early stage when the cancer is treatable. Before a treatment regimen is started, bladder cancers are graded based on the cell type and staged based on the extent and invasiveness of the cancer. A grading system is used to classify the malignant potential of tumor cells, using a scale from well differentiated (closely resembling the normal tissue) to undifferentiated (poorly differentiated) (see p. 254 in Chapter 16).

The clinical staging of bladder cancer is determined by the depth of invasion of the bladder wall and surrounding tissue. Staging of bladder cancer is presented in detail in eTable 46-2 (on the website for this chapter). The following is a simple description of staging of bladder cancer:

Stage I: Cancer is in the inner lining of the bladder but has not invaded the bladder muscle wall.

Stage II: Cancer has invaded the bladder wall but is still confined to bladder.

Stage III: Cancer has spread through the bladder wall to surrounding tissue. It may also have spread to the prostate in men or the uterus or vagina in women.

Stage IV: Cancer has spread to the lymph nodes and other organs, such as lungs, bones, or liver.

Eighty percent of bladder tumors are *superficial,* meaning they do not invade the bladder wall. Low-grade, low-stage bladder cancers are the most responsive to treatment, which includes instillation of intravesical chemotherapy. Although patients with superficial tumors are more easily cured, periodic surveillance is important, since two thirds of patients have tumor recurrence within 5 years and nearly 95% have recurrence by 15 years.

Collaborative care of bladder cancer includes surgery, radiation, chemotherapy, and intravesical therapy (Table 46-15).

SURGICAL THERAPY

Surgical therapies include a variety of procedures. *Transurethral resection of the bladder tumor* (TURBT) is used for superficial lesions of the bladder's inner lining. A wire loop inserted through the cystoscope is used to cauterize (with electric current or laser) and kill the cancer cells. This procedure is also used to

TABLE 46-15 COLLABORATIVE CARE

Bladder Cancer

Diagnostic	Collaborative Therapy

control bleeding in the patient who is a poor operative risk or who has advanced tumors. The primary disadvantage of this approach is destruction of the tumor so pathologic evaluation for grading and staging cannot be completed.

A *segmental cystectomy (partial cystectomy)* is used to treat larger tumors or those that only involve one area of the bladder. A portion of the bladder wall containing the tumor is removed along with a margin of normal tissue.

When the tumor is invasive or involves the trigone (the area where the ureters insert into the bladder) and the patient is free from metastasis beyond the pelvic area, a radical cystectomy is the treatment of choice. A *radical cystectomy* involves removal of the bladder, prostate, and seminal vesicles in men and the bladder, uterus, cervix, urethra, and ovaries in women. After a radical cystectomy, a new way needs to be created for urine to leave the body. This surgical technique is called a urinary diversion (discussed on p. 1095 later in this chapter).

Postoperative instructions for any of these surgical procedures include drinking a large volume of fluid for the first week after the procedure. Teach the patient to self-monitor the color and consistency of the urine. The urine is pink for the first several days after the procedure, but it should not be bright red or contain blood clots. Approximately 7 to 10 days after tumor resection, the patient may observe dark red or rust-colored flecks in the urine. These may be from the healing tumor resection site.

Administer opioid analgesics for a brief period after the procedure, along with stool softeners. Also help the patient and family cope with fears about cancer, surgery, and sexuality. Emphasize the importance of regular follow-up care. Follow-up cystoscopies are required on a regular basis after surgery for bladder cancer.

RADIATION THERAPY AND CHEMOTHERAPY

Radiation therapy can be used in combination with cystectomy or as the primary therapy when the cancer is inoperable or the patient refuses surgery. Chemotherapy drugs used in treating invasive bladder cancer include cisplatin (Platinol), vinblastine (Velban), doxorubicin (Adriamycin), and methotrexate.

INTRAVESICAL THERAPY

Chemotherapy with local instillation of chemotherapeutic or immune-stimulating agents can be delivered directly into the bladder by a urethral catheter.[30] *Intravesical therapy* is usually initiated at weekly intervals for 6 to 12 weeks. The chemotherapy drug is instilled directly into the patient's bladder and retained for about 2 hours. The patient's bladder must be empty before instillation. Change the patient's position every 15 minutes for maximum contact in all areas of the bladder. Maintenance therapy after the initial induction regimen may be beneficial.

Bacille Calmette-Guérin (BCG), a weakened strain of *Mycobacterium bovis*, is the treatment of choice for carcinoma in situ. BCG stimulates the immune system rather than acting directly on cancer cells in the bladder. When BCG fails, α-interferon in addition to BCG may be used. Other treatments that can be used when BCG fails include thiotepa (Thioplex), an alkylating agent, and valrubicin (Valstar), a chemotherapy antibiotic.

Most patients have irritative voiding symptoms and hemorrhagic cystitis after intravesical therapy. Thiotepa can significantly reduce WBC and platelet counts in some individuals when absorbed into the circulation from the bladder wall. BCG may cause flu-like symptoms, increased urinary frequency, hematuria, or systemic infection. Other side effects of chemotherapy (e.g., nausea, vomiting, hair loss) are not experienced with intravesical chemotherapy.

Encourage patients to increase their daily fluid intake and to quit smoking. Assess the patient for secondary UTI, and stress the need for routine urologic follow-up. The patient may have fears or concerns about sexual activity or bladder function that need to be addressed. Because of the high rate of disease recurrence and progression in bladder cancer, follow-up studies are very important.

GENDER DIFFERENCES

Urinary Incontinence

Men	Women
• Urinary incontinence is a common manifestation of benign prostatic hyperplasia and prostate cancer in men. • Urinary incontinence in men most often is overflow incontinence caused by urinary retention.	• Prevalence of urinary incontinence is higher in women than men. • Women more frequently experience stress and urge incontinence than men.

BLADDER DYSFUNCTION

URINARY INCONTINENCE

Urinary incontinence (UI) is an involuntary leakage of urine. Approximately 17 million people in the United States suffer from UI. The prevalence is 30% to 40% among young adult to middle-aged women, and increases to 30% to 50% in older women. In contrast, the incidence of UI in men tends to be considerably lower, ranging from 1% to 5% in young adult men and increasing to 9% to 34% in older men.[31] Although incontinence is more prevalent among older women and older men, it is not a natural consequence of aging. UI has traditionally been viewed as a social or hygienic problem, but it also has a major effect on quality of life and contributes to serious health problems, especially in older adults.

Etiology and Pathophysiology

UI occurs when bladder pressure exceeds urethral closure pressure. Anything that interferes with bladder or urethral sphincter

TABLE 46-16 DRUG THERAPY

Drugs Affecting Lower Urinary Tract Function

Drug	Effect
Alcohol	Polyuria, frequency, urgency, sedation, delirium
α-Adrenergic receptor agonists: pseudoephedrine (Sudafed), ephedrine	Urethral constriction and urinary retention (males)
α-Adrenergic receptor antagonists: prazosin (Minipress), terazosin (Hytrin), doxazosin (Cardura)	Urethral relaxation and stress urinary incontinence in females
ACE inhibitors: captopril (Capoten), lisinopril (Zestril), enalapril (Vasotec)	Cough triggering stress urinary incontinence
Anticholinergics: H_1-antihistamines, antiparkinsonian agents	Urinary retention, overflow incontinence, fecal impaction
Tricyclic antidepressants	Anticholinergic effect, α-adrenergic receptor antagonist effect
β-Adrenergic receptor antagonists: propranolol (Inderal), metoprolol (Toprol, Lopressor), atenolol (Tenormin)	Urinary retention
Calcium channel blockers: verapamil (Calan), diltiazem (Cardizem), nifedipine (Procardia)	Urinary retention, fecal impaction
Opioids	Urinary retention, fecal impaction, sedation, delirium
Sedative-hypnotics	Sedation, delirium, muscle relaxation
Diuretics: loop diuretics such as furosemide (Lasix)	Polyuria, frequency, urgency
Methylxanthines (caffeine, theophylline)	Polyuria, bladder irritation
Antiseizure agents: thioridazine (Mellaril), chlorpromazine (Thorazine)	Anticholinergic effect, sedation

ACE, Angiotensin-converting enzyme.

control can result in UI. Using the acronym *DRIP*, the causes can include *D:* delirium, dehydration, depression; *R:* restricted mobility, rectal impaction; *I:* infection, inflammation, impaction; and *P:* polyuria, polypharmacy. (Table 46-16 lists drugs that can affect the lower urinary tract.) Patients may have more than one type of incontinence (Table 46-17).

Diagnostic Studies

The basic evaluation for UI includes a focused history, a physical assessment, and a bladder log or voiding record whenever possible. Obtain information on the onset of UI, factors that provoke urinary leakage, and associated conditions. Pay special attention to factors known to produce transient UI, particularly when the onset of urine loss is relatively sudden. Begin the physical examination with an assessment of general health and functional issues associated with urination, including mobility, dexterity, and cognitive function.

A pelvic examination includes careful inspection of the perineal skin for signs of erosion or rashes related to UI and existence of pelvic organ prolapse. Also evaluate local innervation and pelvic floor muscle strength, including a digital examination of the pelvic floor muscle to determine weakness or tension. Whenever possible, ask the patient to keep a bladder log or voiding diary documenting the timing of urinations, episodes of urinary leakage, and frequency of nocturia for a period of 1 to 7 days. This record can be kept by nursing staff if the person is in an inpatient or long-term care facility.

A urinalysis is used to identify possible factors contributing to transient UI (e.g., UTI, diabetes mellitus). Measure postvoid residual (PVR) urine in the patient undergoing evaluation for UI. The PVR volume is obtained by asking the patient to urinate, followed by catheterization or use of a bladder ultrasound within a relatively brief period (preferably 10 to 20 minutes).

Urodynamic testing is indicated in selected cases of UI. Imaging studies of the upper urinary tract (e.g., ultrasound) are obtained when UI is associated with UTIs or evidence of upper urinary tract involvement.

COMPLEMENTARY & ALTERNATIVE THERAPIES

Biofeedback

Scientific Evidence

Biofeedback has been shown to be helpful in treating a variety of medical conditions: urinary incontinence, asthma, Raynaud's disease, irritable bowel syndrome, hot flashes, nausea and vomiting associated with chemotherapy, headaches, hypertension, and seizure disorders.*

Nursing Implications

- Feedback from monitoring equipment can teach patients to control certain involuntary body responses, such as urinary incontinence.
- Although biofeedback is considered safe, patients should consult a qualified professional before using biofeedback.

*Based on a systematic review of scientific literature. Retrieved from *www.naturalstandard.com*.

Collaborative Care

An estimated 80% of incontinence can be cured or significantly improved.[32] Transient, reversible factors are corrected initially, followed by management of the type of UI (see Table 46-17). In general, less invasive treatments are attempted before more invasive methods (e.g., surgery). Nevertheless, the choice of the initial treatment is individualized, based on patient preference, the type and severity of UI, and associated anatomic defects.

Several behavioral therapies may be used to improve UI (Table 46-18). Pelvic floor muscle training (Kegel exercises) is used to manage stress, urge, or mixed UI (Table 46-19). Biofeedback is used to help the patient identify, isolate, contract, and relax the pelvic muscles (see the Complementary & Alternative Therapies box on this page).

Drug Therapy. Drug therapy varies according to the UI type (Table 46-20 on p. 1091). In stress UI, drugs have a limited role in the management. α-Adrenergic agonists can be used to increase bladder sphincter tone and urethral resistance, but have limited benefit.

In urge and reflex UI, drugs play a key management role. Anticholinergic drugs and muscarinic receptor antagonists relax the bladder muscle and inhibit overactive detrusor contractions. Several preparations of these drugs are available, including immediate and extended-release tolterodine (Detrol, Detrol LA); immediate, extended-release, and transdermal oxybutynin (Ditropan XL, Oxytrol Transdermal System [also available over-the-counter]); twice-daily trospium chloride (Sanctura); extended-release solifenacin (VESIcare); darifenacin (Enablex); and fesoterodine (Toviaz). Side effects of these drugs include dry mouth, dry eyes, constipation, blurred vision, and somnolence.

TABLE 46-17 TYPES OF URINARY INCONTINENCE

Description	Causes	Treatment
Stress Incontinence*		
Sudden increase in intraabdominal pressure causes involuntary passage of urine. Can occur during coughing, laughing, sneezing, or physical activities such as heavy lifting, exercising. Leakage usually is in small amounts and may not be daily.	Found most commonly in women with relaxed pelvic floor musculature (from delivery, use of instrumentation during vaginal delivery, or multiple pregnancies). Structures of the female urethra atrophy when estrogen decreases. Prostate surgery for BPH or prostate cancer.	Pelvic floor muscle exercises (e.g., Kegel exercises), weight loss if patient is obese, cessation of smoking, topical estrogen products, external condom catheters or penile clamp in men, surgery Urethral inserts, patches, or bladder neck support devices (e.g., incontinence pessary) to correct underlying problem
Urge Incontinence*		
Condition occurs randomly when involuntary urination is preceded by urinary urgency. Seen with overactive bladder symptoms of urgency and frequency. Leakage is periodic but frequent and usually in large amounts. Nocturnal frequency and incontinence are common.	Condition is caused by uncontrolled contraction or overactivity of detrusor muscle. Bladder escapes central inhibition and contracts reflexively. Conditions include: • Central nervous system disorders (e.g., cerebrovascular disease, Alzheimer's disease, brain tumor, Parkinson's disease) • Bladder disorders (e.g., carcinoma in situ, radiation effects, interstitial cystitis) • Interference with spinal inhibitory pathways (e.g., malignant growth in spinal cord, spondylosis) • Bladder outlet obstruction or conditions of unknown etiology	Treatment of underlying cause Biobehavioral interventions, including bladder retraining with urge suppression, decrease in dietary irritants, bowel regularity, and pelvic floor muscle exercises Anticholinergic drugs (e.g., oxybutynin [Ditropan XL, Oxytrol], tolterodine [Detrol, Detrol LA], trospium chloride [Sanctura], solifenacin [VESIcare], and darifenacin [Enablex]); imipramine (Tofranil) at bedtime; calcium channel blockers Containment devices (e.g., external condom catheters) Vaginal estrogen creams Absorbent products
Overflow Incontinence		
Condition occurs when the pressure of urine in overfull bladder overcomes sphincter control. Leakage of small amounts of urine is frequent throughout the day and night. Urination may also occur frequently in small amounts. Bladder remains distended and is usually palpable.	Disorder is caused by bladder or urethral outlet obstruction (bladder neck obstruction, urethral stricture, pelvic organ prolapse) or by underactive detrusor muscle caused by myogenic or neurogenic factors (e.g., herniated disc, diabetic neuropathy). May also occur after anesthesia and surgery (e.g., hemorrhoidectomy, herniorrhaphy, cystoscopy). Neurogenic bladder (flaccid type).	Urinary catheterization to decompress bladder Implementation of Credé or Valsalva maneuver α-Adrenergic blocker (doxazosin [Cardura], terazosin [Hytrin], tamsulosin [Flomax], alfuzosin [Uroxatral]) 5α-Reductase inhibitors (e.g., finasteride [Proscar]) to decrease outlet resistance bethanechol (Urecholine) to enhance bladder contractions Intravaginal device such as a pessary to support prolapse Intermittent catheterization Surgery to correct underlying problem
Reflex Incontinence		
Condition occurs when no warning or stress precedes periodic involuntary urination. Urination is frequent, is moderate in volume, and occurs equally during the day and night.	Spinal cord lesion above S2 interferes with central nervous system inhibition. Disorder results in detrusor hyperreflexia and interferes with pathways coordinating detrusor contraction and sphincter relaxation.	Treatment of underlying cause Bladder decompression to prevent ureteral reflux and hydronephrosis Intermittent self-catheterization diazepam (Valium) or baclofen (Lioresal) to relax external sphincter Prophylactic antibiotics Surgical sphincterotomy
Incontinence After Trauma or Surgery		
In women, vesicovaginal or urethrovaginal fistula may occur. In men, alteration in continence control involves proximal urethral sphincter (bladder neck and prostatic urethra) and distal urethral sphincter (external striated muscle).	Fistulas may occur during pregnancy, after delivery of baby, as a result of hysterectomy or invasive cancer of cervix, or after radiation therapy. Incontinence is a postoperative complication of transurethral, perineal, or retropubic prostatectomy.	Surgery to correct fistula Urinary diversion surgery to bypass urethra and bladder External condom catheter Penile clamp Placement of artificial implantable sphincter
Functional Incontinence		
Loss of urine resulting from cognitive, functional, or environmental factors.	Older adults often have problems that affect balance and mobility.	Modifications of environment or care plan that facilitates regular, easy access to toilet and promotes patient safety (e.g., better lighting, removal of scatter rugs, ambulatory assistance equipment, clothing alterations, timed voiding, different toileting equipment)

*Patients can have a combination of stress and urge incontinence, referred to as mixed incontinence.

Botox (onabotulinumtoxin A) can be used in the treatment of UI as a result of detrusor overactivity. Botox is injected into the bladder, resulting in relaxation of the bladder, an increase in its storage capacity, and a decrease in UI.

DRUG ALERT: Tolterodine (Detrol)

- Overdosage can result in severe anticholinergic effects.
- These effects include GI cramping, diaphoresis, blurred vision, and urinary urgency.

Surgical Therapy. Surgical techniques also vary depending on the type of UI. Surgical correction of stress UI is aimed at making the urinary structures more receptive to intraabdominal pressure and augmenting the urethral resistance of the internal sphincter. It may involve repositioning the urethra and/or creating a backboard of support to stabilize the urethra and bladder neck and make them more receptive to changes in intraabdominal pressure. Another technique for stress UI augments the urethral resistance of the intrinsic sphincter with a sling or periurethral injectables.

Retropubic colposuspension and pubovaginal sling placement appear to be most effective. Typically, both procedures are performed through low transverse incisions. Complications specific to the retropubic suspensions include postoperative voiding dysfunction, urgency, and vaginal prolapse.

Placement of a suburethral sling, using the person's own fascia, cadaveric fascia, or a synthetic material, is also used to correct stress UI in women. Complications include vascular and bowel injury, urinary retention, mesh or sling erosion, infection, urgency, and bladder perforation. Suburethral slings have success rates comparable to those of colposuspensions or slings and are associated with shorter recovery periods. An artificial urethral sphincter can be used in men with intrinsic sphincter deficiency and severe stress UI.

Alternatively, one of several bulking agents can be injected underneath the mucosa of the urethra to correct stress UI in women or men. Bulking agents include glutaraldehyde cross-linked bovine collagen (GAX collagen), small silicone beads (Durasphere), or polytetrafluoroethylene (Teflon). Because of the risk of migration of Teflon particles, GAX collagen or Durasphere injections are most commonly used today. Although treatment with suburethral compounds avoids the risk associated with open surgery, reinjection is typically required after several years.

Injecting autologous stem cells into the rhabdosphincter and urethral submucosa of women is a recent experimental therapy for stress UI. This technique increases urethral closure pressure and periurethral electromyography activity. However, the injection requires use of transurethral ultrasonography for correct placement of the stem cells.[33]

NURSING MANAGEMENT URINARY INCONTINENCE

It is important to recognize both the physical and the emotional problems associated with UI. Maintain and enhance the patient's dignity, privacy, and feelings of self-worth. This is a two-step approach: (1) containment devices to manage existing urinary leakage and (2) a definitive plan to reduce or resolve the factors leading to UI.

Management options are reviewed in Tables 46-18 and 46-19. They include lifestyle interventions such as teaching the patient about consumption of an adequate volume of fluids and reduction or elimination of bladder irritants (particularly

TABLE 46-18 INTERVENTIONS FOR URINARY INCONTINENCE

Intervention	Description
Lifestyle Modifications	Self-management strategies to reduce or eliminate risk factors, including the following: • Smoking cessation • Weight reduction • Good bowel regimen • Reduction of bladder irritants (e.g., caffeine, aspartame artificial sweetener, citrus juices) • Fluid modifications for those with urge incontinence
Scheduled Voiding Regimens	
Timed voiding	Toileting on a fixed schedule (typically every 2-3 hr during waking hours).
Habit retraining	Scheduled toileting with adjustments of voiding intervals (longer or shorter) based on the individual's voiding pattern.
Prompted voiding	Scheduled toileting that requires prompts to void from a caregiver (typically every 3 hr). Used in conjunction with operant conditioning techniques to reward individuals for maintaining continence and appropriate toileting.
Bladder retraining and urge-suppression strategies	Scheduled toileting with progressive voiding intervals. Includes teaching of urge-control strategies using relaxation and distraction techniques, self-monitoring, reinforcement techniques, and other strategies such as conscious contraction of pelvic floor muscles.
Pelvic Floor Muscle Rehabilitation	
Pelvic floor muscle (Kegel) exercises or training	See Table 46-19.
Vaginal weight training	Active retention of increasing vaginal weights at least twice a day. Typically used in combination with pelvic floor muscle exercises.
Biofeedback	See Complementary & Alternative Therapies box on p. 1087.
Electrical stimulation	Application of low-voltage electric current to sacral and pudendal afferent fibers through vaginal, anal, or surface electrodes. Used to inhibit bladder overactivity and improve awareness, contractility, and efficiency of pelvic muscle contraction.
Anti-Incontinence Devices	
Intravaginal support devices (pessaries and bladder neck support prostheses)	Devices support bladder neck, relieve minor pelvic organ prolapse, and change pressure transmission to the urethra.
Intraurethral occlusive device (urethral plug)	Single-use device that is worn in the urethra to provide mechanical obstruction to prevent urine leakage. Removed for voiding.
Penile compression device	Mechanical fixed compression applied to the penis to prevent any flow or leakage via the urethra. Must be released hourly to void.
Containment Devices	
External collection devices	External catheter (condom) systems (e.g., penile sheaths) direct urine into a drainage bag. Most commonly used by men.
Absorbent products	Variety of reusable and disposable pads and undergarment systems.

TABLE 46-19 PATIENT TEACHING GUIDE

Pelvic Floor Muscle (Kegel) Exercises

Include the following instructions when teaching the patient to perform Kegel exercises.

What Is the Pelvic Floor Muscle?

- Your pelvic floor muscle provides support for your bladder and rectum and, in women, the vagina and the uterus.
- If it weakens or is damaged, it cannot support these organs and their position can change.
- This causes problems with the normal bladder and rectal function.
- If you have a weak pelvic floor muscle, you might want to do special exercises to make the muscle stronger, prevent unwanted urine leakage, and lessen urinary urgency.

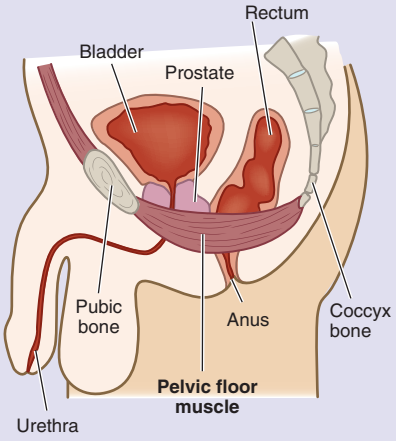
Finding the Pelvic Floor Muscle

- Without tensing the muscles of your leg, buttocks, or abdomen, imagine that you are trying to control the passing of gas or pinching off a stool.
- Or imagine you are in an elevator full of people and you feel the urge to pass gas. What do you do?
- You tighten or pull in the ring of muscle around your rectum—your pelvic floor muscle.
- You should feel a lifting sensation in the area around the vagina or a pulling in of your rectum.

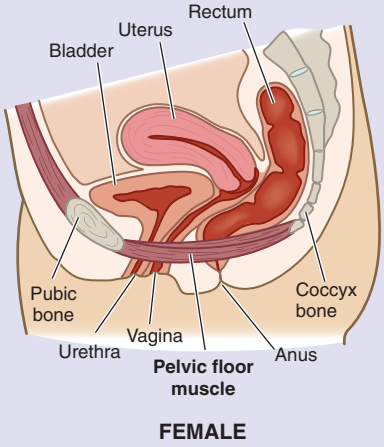
How to Do the Exercises

There are two different kinds of exercises—short squeezes and long squeezes.

1. To do the *short squeezes,* tighten your pelvic floor muscle quickly, squeeze hard for 2 sec, and then relax the muscle. Also, when you have strong urinary urges, try to tighten your pelvic floor muscle quickly and hard several times in a row until the urge passes.
2. To do the *long squeezes,* tighten the muscle for 5-10 sec before you relax.



Do both of these exercises 40-50 times each day.



When to Do These Exercises

- You can do these exercises anytime and anywhere.
- You can do these exercises in any position, but sitting or lying down may be the easiest.

How Long Does It Take Before I Notice a Change?

After 4-6 wk of doing these exercises, you should start to see less urine leakage and urinary urgency.

Courtesy Diane Newman.

caffeine and alcohol) from the diet. Advise the patient to maintain a regular, flexible schedule of urination (usually every 2 to 3 hours while awake). Advise patients to quit smoking because this habit increases the risk of stress UI. Counsel patients about the relationship among constipation, UI, and urinary retention. Aggressive management of constipation is recommended, beginning with ensuring adequate fluid intake, increasing dietary fiber, lightly exercising, and judiciously using stool softeners. (The management of constipation is discussed in Chapter 43.)

Behavioral treatments include scheduled voiding regimens (timed voiding, habit training, and prompted voiding), bladder retraining, and pelvic floor muscle training. Assess strategies that the patient uses to contain UI and offer alternative devices when indicated. When attempting to manage UI, many women use feminine hygiene pads, and many men and women use household products such as rags, paper towels, or folded toilet tissue. Unfortunately, none of these products is adequately designed to wick urine away from the skin, prevent soiling of clothing, and reduce or eliminate odor.

Instead, provide information on products specifically designed to contain urine. For example, patients with mild to moderate UI often benefit from incontinent pads containing superabsorbent material, designed to absorb many times its weight in water. Patients with higher-volume urine loss or those with both urinary and fecal incontinence may benefit from disposable or reusable incontinence protective underwear, briefs, or pad/pant systems.

In inpatient or long-term care facilities, nursing management of UI includes maximizing toilet access. This assistance may take the form of offering the urinal or bedpan or assisting the patient to the bathroom every 2 to 3 hours or at scheduled times. Ensure that toilets are accessible to patients and provide privacy to allow effective urine elimination.

URINARY RETENTION

Urinary retention is the inability to empty the bladder when a person voids (micturition) or the accumulation of urine in the bladder because of an inability to urinate. In certain cases, it is

TABLE 46-20 DRUG THERAPY

Voiding Dysfunction*

Class and Mechanism of Action	Drug
Muscarinic Receptor Antagonists and Anticholinergics	
Reduce overactive bladder contractions in urge urinary incontinence and overactive bladder	oxybutynin (Ditropan IR, Ditropan XL, Oxytrol Transdermal System) tolterodine (Detrol, Detrol LA) trospium chloride (Sanctura) solifenacin (VESIcare) darifenacin (Enablex) hyoscyamine (Levsin, Levbid) dicyclomine (Bentyl) flavoxate (Urispas) propantheline (Pro-Banthine) fesoterodine (Toviaz)
α-Adrenergic Antagonists	
Reduce urethral sphincter resistance to urinary outflow	doxazosin (Cardura) terazosin (Hytrin) tamsulosin (Flomax) alfuzosin (Uroxatral)
5α-Reductase Inhibitors	
Androgen suppression that results in epithelial atrophy and a decrease in total prostate size	finasteride (Proscar) dutasteride (Avodart)
α-Adrenergic Agonists	
Increase urethral resistance	phenylpropanolamine pseudoephedrine
β_3-Adrenergic Agonist	
Improves the bladder's storage capacity by relaxing the bladder muscle during filling	mirabegron (Myrbetriq)
Tricyclic Antidepressants	
Reduce sensory urgency and burning pain of interstitial cystitis Reduce overactive bladder contractions	imipramine (Tofranil) amitriptyline (Elavil)
Calcium Channel Blockers	
Reduce smooth muscle contraction strength May reduce burning pain of interstitial cystitis	nifedipine (Adalat) diltiazem (Cardizem) verapamil (Calan, Isoptin)
Hormone Therapy	
Local application reduces urethral irritation and increases host defenses against UTI	estrogen cream (Premarin, Estrace) estrogen vaginal ring (Estring) estrogen vaginal tablets (Vagifem)

*The type of drug therapy depends on the type of incontinence.

DELEGATION DECISIONS

Caring for the Incontinent Patient

All members of the health care team are responsible for decreasing the risk for incontinence and preventing complications such as skin breakdown in patients who are experiencing incontinence.

Role of Registered Nurse (RN)

- Assess for risk factors for incontinence or urinary retention.
- Determine type of incontinence that patient is experiencing.
- Develop plan of care to decrease incontinence.
- Teach patient ways to decrease incontinence such as pelvic floor muscle (Kegel) exercises.
- Assist patient in choosing appropriate products to contain urine.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Use bladder scanner to estimate the postvoid residual volume (PVR).
- Catheterize patient and measure PVR.
- Administer medications to decrease incontinence or urinary retention.

Role of Unlicensed Assistive Personnel (UAP)

- Assist incontinent patient to commode or bedpan at regular intervals.
- Clean patient and provide skin care.
- Notify RN about new-onset incontinence in a previously continent patient.

associated with urinary leakage or postvoid dribbling, called *overflow UI. Acute urinary retention* is the total inability to pass urine via micturition. It is a medical emergency. *Chronic urinary retention* is an incomplete bladder emptying despite urination. The postvoid residual (PVR) volumes in patients with chronic urinary retention vary widely. Normal PVR is between 50 and 75 mL. Findings over 100 mL indicate the need to repeat the measurement. An abnormal PVR in the older patient of more than 200 mL obtained on two separate occasions requires further evaluation. Even smaller volumes may justify further evaluation when the patient has recurring UTIs or lower urinary tract symptoms suggestive of UTI.

Etiology and Pathophysiology

Urinary retention is caused by two different dysfunctions of the urinary system: bladder outlet obstruction and deficient detrusor (bladder muscle) contraction strength. *Bladder outlet obstruction* leads to urinary retention when the blockage is so severe that the bladder can no longer evacuate its contents despite a detrusor contraction. A common cause of obstruction in men is an enlarged prostate.

Deficient detrusor contraction strength leads to urinary retention when the muscle is no longer able to contract with enough force or for a sufficient time to completely empty the bladder. Common causes of deficient detrusor contraction strength are neurologic diseases affecting sacral segments 2, 3, and 4; long-standing diabetes mellitus; overdistention; chronic alcoholism; and drugs (e.g., anticholinergic drugs).

Diagnostic Studies

The diagnostic studies for urinary retention are the same as the ones for UI (see pp. 1066-1067).

Collaborative Care

Behavioral therapies that were described for UI may also be used in the management of urinary retention. Scheduled toileting and double voiding may be effective in chronic urinary retention with moderate PVR volumes. *Double voiding* is an attempt to maximize bladder evacuation. The patient is asked to urinate, sit on the toilet for 3 to 4 minutes, and urinate again before exiting the bathroom.

For acute or chronic urinary retention, catheterization may be required. Intermittent catheterization allows the patient to remain free of an indwelling catheter with its associated risk of UTI and urethral irritation. In some situations, an indwelling catheter is preferred (e.g., if the patient is unwilling or unable

to perform intermittent catheterization). An indwelling catheter is also used when urethral obstruction makes intermittent catheterization uncomfortable or infeasible.

Drug Therapy. Several drugs may be administered to promote bladder evacuation. For the patient with obstruction at the level of the bladder neck, an α-adrenergic blocker may be prescribed. These drugs relax the smooth muscle of the bladder neck, the prostatic urethra, and possibly the rhabdosphincter, diminishing urethral resistance. Examples of α-adrenergic blocking agents are listed in Table 46-20. They are indicated in patients with BPH, bladder neck dyssynergia (muscle incoordination), or detrusor sphincter dyssynergia.

Surgical Therapy. Surgical interventions are used to manage urinary retention caused by obstruction. Transurethral or open surgical techniques are used to treat benign or malignant prostatic enlargement, bladder neck contracture, urethral strictures, or dyssynergia of the bladder neck. Pelvic reconstruction using an abdominal or transvaginal approach can correct bladder outlet obstruction in women with severe pelvic organ prolapse.

Unfortunately, surgery has a minimal role in the management of urinary retention caused by deficient detrusor contraction strength. Attempts to create a bladder stimulator (implanted device capable of stimulating micturition) have proved largely unsuccessful because of the difficulty in achieving a coordinated detrusor contraction associated with pelvic muscle and striated sphincter relaxation.

NURSING MANAGEMENT URINARY RETENTION

Acute urinary retention is a medical emergency that requires prompt recognition and bladder drainage. Insert a catheter (as ordered) unless otherwise directed. Use a catheter with a retention balloon in anticipation of the need for an indwelling catheter.

Teach the patient with acute urinary retention (and the patient predisposed to these episodes) strategies to minimize risk, including avoiding intake of large volumes of fluid over a brief period. Instead, advise the patient to drink small amounts throughout the day. In addition, instruct the patient (if chilled) to warm up before attempting to urinate and to avoid excessive alcohol intake because it leads to polyuria and a diminished awareness of the need to urinate until the bladder is distended.

Advise the patient who is unable to urinate to drink a cup of coffee or brewed caffeinated tea to create or maximize urinary urgency. Tell patients that sitting in a tub of warm water or taking a warm shower may also help them urinate. If these measures do not lead to successful urination, advise the patient to seek immediate care.

Patients with chronic urinary retention may be managed by behavioral methods, indwelling or intermittent catheterization, surgery, or drugs. Scheduled toileting and double voiding are the primary behavioral interventions used for chronic retention. Scheduled toileting is used to reduce rather than expand bladder capacity. In this case, ask the patient to void every 3 to 4 hours regardless of the desire to urinate. This intervention is particularly useful in the patient with chronic overdistention, diabetes mellitus, or chronic alcoholism characterized by a large bladder capacity and diminished or delayed sensations of bladder filling and urgency.

TABLE 46-21 INDICATIONS FOR URINARY CATHETERIZATION

Indwelling Catheter

- Relief of urinary retention caused by lower urinary tract obstruction, paralysis, or inability to void
- Bladder decompression preoperatively and operatively for lower abdominal or pelvic surgery
- Facilitation of surgical repair of urethra and surrounding structures
- Splinting of ureters or urethra to facilitate healing after surgery or other trauma in area
- Accurate measurement of urine output in critically ill patient
- Contamination of stage III or IV pressure ulcers with urine that has impeded healing, despite appropriate personal care for the incontinence
- Terminal illness or severe impairment, which makes positioning or clothing changes uncomfortable, or which is associated with intractable pain

Intermittent (Straight, In and Out) Catheter

- Study of anatomic structures of urinary system
- Urodynamic testing
- Collection of sterile urine sample in selected situations
- Instillation of medications into bladder
- Measurement of residual urine after urination (postvoid residual [PVR]) if portable ultrasound not available

CATHETERIZATION

INDICATIONS FOR AND COMPLICATIONS OF CATHETERIZATION

Indications for short-term urinary catheterization are listed in Table 46-21. Two unacceptable reasons for catheterization are (1) routine acquisition of a urine specimen for laboratory analysis and (2) convenience of the nursing staff or the patient's family. The risks of HAI are too high to allow catheterization of a patient for the convenience of hospital personnel or family members.

Complications that are seen more frequently with long-term use (more than 30 days) of indwelling catheters include HAIs, bladder spasms, periurethral abscess, pain, urosepsis, UTIs, urethral trauma or erosion, fistula or stricture formation, and stones. Catheterization for sterile urine specimens may occasionally be necessary when patients have a history of complicated UTI. A catheter should be the final resort to provide the patient with a dry environment to prevent skin breakdown and protect dressings or skin lesions.

Urinary catheterization is commonly used in the management of the hospitalized patient. However, it is not without serious complications. The urinary tract is the most common site of HAIs. Urinary catheterization is a major cause of UTIs. Scrupulous aseptic technique is mandatory when a urinary catheter is inserted. After insertion, maintenance and protection of the closed drainage system are major nursing responsibilities. Do not routinely irrigate the catheter; this should be done only if ordered.

While the patient has a catheter in place, maintain patency of the catheter, manage fluid intake, provide for the patient's comfort and safety, and prevent infection. Address the psychologic implications of urinary drainage. Patient concerns can include embarrassment related to exposure of the body, an altered body image, and fear that care of the catheter will result in increased dependency.

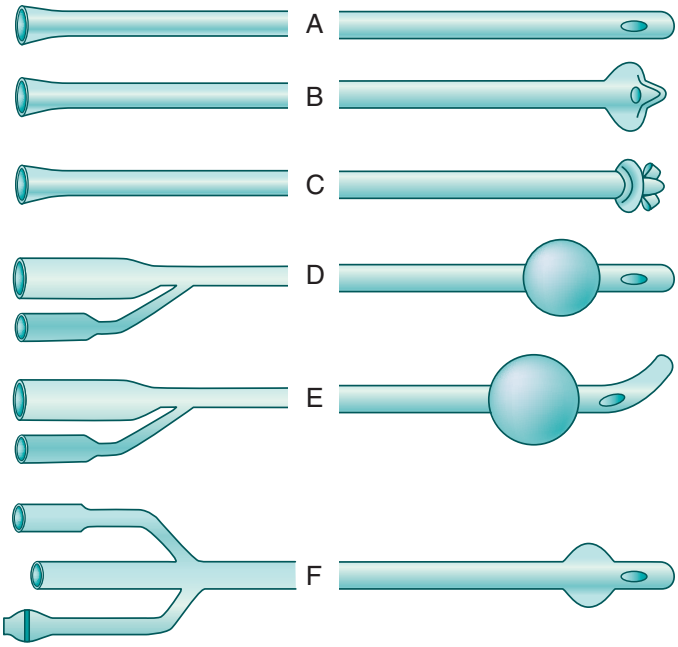


FIG. 46-10 Types of urinary catheters. **A,** Simple urethral catheter. **B,** Mushroom-tip de Pezzer catheter (can be for suprapubic catheterization). **C,** Wing-tip Malecot catheter. **D,** Indwelling urethral catheter with inflated balloon. **E,** Indwelling Tiemann catheter with coudé-tip–inflated balloon. **F,** Three-way indwelling catheter (third lumen can be used for irrigation).

CATHETER CONSTRUCTION

Catheter materials include Teflon-coated latex, silicone elastomer, and hydrogel-coated silicone. Catheters coated with silver or antimicrobial agents may prevent UTIs.

Catheters vary in construction materials, tip shape (Fig. 46-10), and size of the lumen. A coudé-tip catheter is commonly used in men. Catheters are sized according to the French scale. Each French unit (F) equals 0.33 mm of diameter. The diameter listed is the internal diameter of the catheter. The size used varies with the patient's size and the purpose of catheterization. In women, urethral catheter sizes 14F to 16F are the most common. In men, sizes 14F to 18F are used. Balloon sizes are either 5 or 30 mL. The primary problem resulting from too large a catheter is tissue erosion secondary to excessive pressure on the meatus or urethra.

TYPES OF CATHETERS

Four routes are used for urinary tract catheterization: urethral, ureteral, suprapubic, and via a nephrostomy tube.

Urethral Catheters

Urethral catheterization, the most common route of catheterization, involves the insertion of a catheter through the external meatus into the urethra, past the internal sphincter, and into the bladder. Consider the following principles in the management of the patient with an indwelling urethral catheter:

- Teach catheter care to the catheterized patient, particularly one who is ambulatory.
- Use a sterile, closed drainage system in short-term catheterization. Do not disconnect the distal urinary catheter and the proximal drainage tube except for necessary catheter irrigation. Maintain unobstructed downhill flow. Empty the collecting bag regularly, and keep it below the level of the bladder. Replace a poorly functioning catheter.
- Provide perineal care (once or twice a day and when necessary), including cleaning the meatus-catheter junction with soap and water. Do not use lotion or powder near the catheter.
- Anchor catheters using some type of securement device. It is recommended that the catheter be anchored to the upper thigh in women and to the lower abdomen in men to prevent catheter movement and urethral tension.
- Use sterile technique whenever the collecting system is open. If frequent irrigations are necessary in short-term catheterization to maintain catheter patency, a triple-lumen catheter may be preferable, permitting continuous irrigations within a closed system.
- Aspirate small volumes of urine for culture from the catheter sampling port by means of a sterile syringe and a needle. First prepare the puncture site with a tincture of iodine or alcohol solution.
- When the patient is catheterized for less than 2 weeks, routine catheter change is not necessary. For long-term use of an indwelling catheter, replace the catheter based on patient assessment and not on a routine changing schedule.
- With long-term use of a catheter, a leg bag may be used. If the collection bag is reused, wash it in soap and water and rinse thoroughly. When it is not reused immediately, fill it with ½ cup of vinegar and drain. The vinegar is effective against *Pseudomonas* and other organisms and eliminates odors.
- Remove the catheter as early as possible. Intermittent catheterization and external catheters are alternatives that may be associated with fewer cases of bacteriuria and UTI than chronic indwelling urethral catheters.

Ureteral Catheters

The *ureteral catheter* is placed through the ureters into the renal pelvis. The catheter is inserted either (1) by being threaded up the urethra and bladder to the ureters under cystoscopic observation or (2) by surgical insertion through the abdominal wall into the ureters. The ureteral catheter is used after surgery to

DELEGATION DECISIONS

Urinary Catheters

Role of Registered Nurse (RN)

- Determine need for catheterization.
- Choose appropriate type and size of catheter.
- Insert catheter in patient with urethral trauma, pain, or obstruction.
- Develop plan of care to decrease risk for infection in patient with indwelling catheter.

Role of Licensed Practical/Vocational Nurse (LPN/LVN)

- Insert intermittent or indwelling catheter for uncomplicated patients.
- Irrigate the catheter if obstruction is suspected in stable patients (e.g., in long-term care).

Role of Unlicensed Assistive Personnel (UAP)

- Provide perineal care around the catheter with soap and water.
- Anchor the catheter in place (upper thigh in women and lower abdomen in men).
- Notify RN about changes in skin condition, especially around meatus.

splint the ureters and to prevent them from being obstructed by edema. Record the urine volume from the ureteral catheter separately from that of other urinary catheters.

The patient is often kept on bed rest while a ureteral catheter is in place until specific orders indicate that ambulation is permitted. The self-retaining ureteral catheter is often inserted after a lithotripsy procedure or when ureteral obstruction from adjacent tumors or fibrosis threatens renal function. The double-J ureteral catheter is frequently used and allows the patient to ambulate. One end coils up in the kidney pelvis, while the other coils in the bladder.

Check the placement of the ureteral catheter frequently, and avoid tension on the catheter. The catheter drains urine from the renal pelvis, which has a capacity of 3 to 5 mL. If the volume of urine in the renal pelvis increases, tissue damage to the pelvis will result from pressure. Do not clamp the ureteral catheter. If the physician orders irrigation of the ureteral catheter, use strict aseptic technique. If the output is decreased, notify the physician immediately. Check the drainage often (at least every 1 or 2 hours). It is normal for some urine to drain around the ureteral catheter into the bladder. Accurately record the urine output from both the ureters and the urethral catheter. Sometimes a ureteral catheter may be used as a stent and is not expected to drain. It is important to check with the physician as to the type of catheter and what to expect.

Suprapubic Catheters

Suprapubic catheterization is the simplest and oldest method of urinary diversion. The two methods of insertion of a suprapubic catheter into the bladder are (1) through a small incision in the abdominal wall and (2) by the use of a trocar. A suprapubic catheter is placed while the patient is under general anesthesia for another surgical procedure or at the bedside with a local anesthetic. The catheter may be sutured into place. Tape the catheter to prevent dislodgment. The care of the tube and catheter is similar to that of the urethral catheter. A pectin-base skin barrier (e.g., Stomahesive) is effective in protecting the skin around the insertion site from breakdown.

The suprapubic catheter is used in temporary situations such as bladder, prostate, and urethral surgery. The suprapubic catheter is also used on a long-term basis in selected patients.

A suprapubic catheter is prone to poor drainage because of mechanical obstruction of the catheter tip by the bladder wall, sediment, and clots. To ensure patency of the tube (1) prevent tube kinking by coiling the excess tubing and maintaining gravity drainage, (2) have the patient turn from side to side, and (3) milk the tube. If these measures are not effective, obtain a physician order to irrigate the catheter using sterile technique.

If the patient experiences bladder spasms that are difficult to control, urinary leakage may result. Oxybutynin or other oral antispasmodics or belladonna and opium (B&O) suppositories may be prescribed to decrease bladder spasms.

Nephrostomy Tubes

The *nephrostomy tube* (catheter) is inserted on a temporary basis to preserve renal function when a ureter is completely obstructed. The tube is inserted through a small flank incision directly into the pelvis of the kidney and attached to connecting tubing for closed drainage. The principle is the same as with the ureteral catheter—that is, the catheter should never be kinked, compressed, or clamped. If the patient complains of excessive pain in the area or if there is excessive drainage around the tube, check the catheter for patency. If irrigation is ordered, use strict aseptic technique. Gently instill no more than 5 mL of sterile saline solution at one time to prevent overdistention of the kidney pelvis and renal damage. Infection and secondary stone formation are complications associated with the insertion of a nephrostomy tube.

Intermittent Catheterization

An alternative approach to a long-term indwelling catheter is *intermittent catheterization,* often referred to as "straight" catheterization or "in-and-out" catheterization. The main goal of intermittent catheterization is to prevent urinary retention, stasis, and compromised blood supply to the bladder caused by prolonged pressure.

It is being used with increasing frequency in conditions such as neurogenic bladder (e.g., spinal cord injuries, chronic neurologic diseases) or bladder outlet obstruction in men. This type of catheterization is used in the oliguric and anuric phases of acute kidney injury to reduce the possibility of infection from an indwelling catheter. Intermittent catheterization is also used postoperatively after a surgical procedure to treat UI.

The technique consists of inserting a urethral catheter into the bladder every 3 to 5 hours. Some patients perform intermittent catheterization only once or twice a day to measure residual urine and to ensure an empty bladder.

The techniques and protocols for intermittent catheterization vary. Catheters can be sterile (single use) or clean (multiple use). Catheters can be coated (prelubricated) or uncoated. Available data on intermittent catheterization do not provide convincing evidence that any specific technique (sterile or clean), catheter type (coated or uncoated), method (single-use or multiple-use), person (self or other), or strategy is better than any other for all clinical settings.[34]

The design of single-use, self-lubricating, silicone-coated (closed-sterile) systems is useful for patients who have recurrent UTIs or need to catheterize while at work or during travel. Instruct patients to wash and rinse the catheter and their hands with soap and water before and after catheterization. Lubricant is necessary for men and may make catheterization more comfortable for women. The catheter may be inserted by the patient, caregiver, or health care provider.

Sterile technique is used for catheterization in the hospital or long-term care facility. For home care, a clean technique that includes good hand washing with soap and water is used. Teach the patient to observe for signs of UTI so that treatment can be instituted early. If indicated, some patients are placed on a regimen of prophylactic antibiotics. Urethral damage from intermittent catheterization in men is similar to problems seen with indwelling catheterization. Complications include urethritis, urethral sphincter damage (especially if there is a forceful catheterization against a closed sphincter), urethral stricture, and creation of a false passage.

SURGERY OF THE URINARY TRACT

RENAL AND URETERAL SURGERY

The most common indications for nephrectomy are a renal tumor, polycystic kidneys that are bleeding or severely infected, massive traumatic injury to the kidney, and the elective removal of a kidney from a donor to be transplanted. Surgery involving the ureters and kidneys is most commonly performed to remove

calculi that become obstructive, correct congenital anomalies, and divert urine when necessary.

Surgical Procedure

Nephrectomy can be performed by a conventional (open) approach or laparoscopically. In the open approach an incision of about 6 to 10 in is made through several layers of muscle. The incision can be made in the flank or abdominal area.

Laparoscopic Nephrectomy. *Laparoscopic nephrectomy* can be performed in selected situations to remove a diseased kidney. Laparoscopic nephrectomy can also be used to obtain a kidney from a living donor to be transplanted into a person with ESKD. A laparoscopic nephrectomy is performed using five puncture sites. One incision is to view the kidney, and another is to dissect it. The laparoscope contains a miniature camera so that the surgeons can watch what they are doing on a video monitor. Once dissected, the kidney is maneuvered into a nylon impermeable sack and then safely removed from the patient. Compared with conventional nephrectomy, the laparoscopic approach is less painful, involves a shorter hospital stay, and has a much faster recovery.

Preoperative Management

The basic needs of the patient undergoing renal and ureteral surgery are similar to those of any patient who experiences surgery (see Chapters 18 through 20). In addition, it is important preoperatively to ensure adequate fluid intake and a normal electrolyte balance. Tell the patient that, if there is a flank incision, surgery will require a hyperextended, side-lying position. This position frequently causes the patient to experience muscle aches after surgery. If a nephrectomy is planned, it is important that the patient have one working kidney to maintain normal renal function.

Postoperative Management

Specific postoperative needs of a patient are related to urine output, respiratory status, and abdominal distention.

Urine Output. In the immediate postoperative period, measure and record the urine output at least every 1 or 2 hours. Measure drainage from the various catheters and record it separately. Do not clamp or irrigate the catheter or tube without a specific order. The total urine output should be at least 0.5 mL/kg/hr. It is important to assess for urine drainage on the dressing and to estimate this amount. Observe and monitor the color and consistency of urine. Urine with increased amounts of mucus, blood, or sediment may occlude the drainage tubing or catheter.

Weigh the patient daily using the same scale, and have the patient wear similar clothing and dressings each time. A significant change in daily weight can indicate retention of fluids, which places the patient at cardiovascular risk for developing heart failure. Retention of fluids can increase the work required of the remaining kidney to perform its functions.

Respiratory Status. A nephrectomy can be performed through a flank incision just below the diaphragm. Postoperatively, it is important to ensure adequate ventilation. The patient is often reluctant to turn, cough, and deep breathe because of the incisional pain. Give adequate pain medication to ensure the patient's comfort and ability to perform coughing and deep-breathing exercises. Frequently, additional respiratory devices such as an incentive spirometer are used every 2 hours while the patient is awake. In addition, early and frequent ambulation assists in maintaining adequate respiratory function.

Abdominal Distention. Abdominal distention is present to some degree in most patients who have had surgery on their kidneys or ureters. It is most commonly due to paralytic ileus caused by manipulation and compression of the bowel during surgery. Oral intake is restricted until bowel sounds are present (usually 24 to 48 hours after surgery). IV fluids are given until the patient can take oral fluids. Progression to a regular diet follows.

URINARY DIVERSION

Urinary diversion may be performed with or without cystectomy. Urinary diversion procedures are performed to treat cancer of the bladder, neurogenic bladder, congenital anomalies, strictures, trauma to the bladder, and chronic infections with deterioration of renal function. Numerous urinary diversion techniques and bladder substitutes are possible, including an incontinent urinary diversion, a continent urinary diversion catheterized by the patient, or an orthotopic bladder so that the patient voids urethrally.[35] Types of surgical procedures for urinary diversion are presented in Table 46-22 and Fig. 46-11.

Incontinent Urinary Diversion

Incontinent urinary diversion is diversion to the skin, requiring an appliance. The simplest form is the cutaneous ureterostomy, but scarring and strictures of the ureter have led to the use of ileal or colonic conduits. The most commonly performed incontinent urinary diversion procedure is the **ileal conduit** (ileal loop). In this procedure a 6- to 8-in (15- to 20-cm) segment of the ileum is converted into a conduit for urinary drainage. The colon (colon conduit) can be used instead of the ileum. The ureters are anastomosed into one end of the conduit, and the other end of the bowel is brought out through the abdominal wall to form a stoma (Fig. 46-12). Although the segment of bowel remains supported by the mesentery, it is completely isolated from the intestinal tract. The bowel is anastomosed and continues to function normally.

Because there is no valve and no voluntary control over the stoma, drops of urine flow from the stoma every few seconds, requiring a permanent external collecting device. The visible stoma and the need for external collection devices are disadvantages of this procedure. The lifelong need to care for and deal with the stoma and collection devices may be psychologically difficult. These problems have led to the increasing use of continent diversions and orthotopic bladder substitutes.

Continent Urinary Diversions

A *continent urinary diversion* is an intraabdominal urinary reservoir that can be catheterized or that has an outlet controlled by the anal sphincter. Continent diversions are internal pouches created similarly to the ileal conduit. Reservoirs are constructed from the ileum, ileocecal segment, or colon. Large segments of bowel are altered to prevent peristaltic action. A continence mechanism is formed between this large, low-pressure reservoir and the stoma by intussuscepting a portion of bowel. In this way, a patient does not leak involuntarily. The patient with a continent reservoir needs to self-catheterize every 4 to 6 hours but does not need to wear external attachments. Patients may wear a small bandage on the stoma to collect any mucous drainage or excess drainage. Examples of continent diversions are the Kock (Fig. 46-13), Mainz, Indiana, and Florida pouches. The main difference among the various diversions is the segment of

TABLE 46-22 URINARY DIVERSION SURGERY

Description	Advantages	Disadvantages	Special Considerations
Ileal Conduit Ureters are implanted into part of ileum or colon that has been resected from intestinal tract. Abdominal stoma is created.	Relatively good urine flow with few physiologic alterations.	External appliance necessary to continually collect urine.	Surgical procedure is complex. Postoperative complications may be increased. Reabsorption of urea by ileum occurs. Meticulous attention is necessary to care for stoma and collecting device.
Cutaneous Ureterostomy Ureters are excised from bladder and brought through abdominal wall, and stoma is created. Ureteral stomas may be created from both ureters, or ureters may be brought together and one stoma created.	No need for major surgery as required with ileal conduit.	External appliance necessary because of continuous urine drainage. Possibility of stricture or stenosis of small stoma.	Periodic catheterizations may be required to dilate stomas to maintain patency.
Nephrostomy Catheter is inserted into pelvis of kidney. Procedure may be done to one or both kidneys and may be temporary or permanent. It is most frequently done in advanced disease as palliative procedure.	No need for major surgery.	High risk of renal infection. Predisposition to calculus formation from catheter.	Nephrostomy tube may have to be changed every month. Never clamp the catheter.

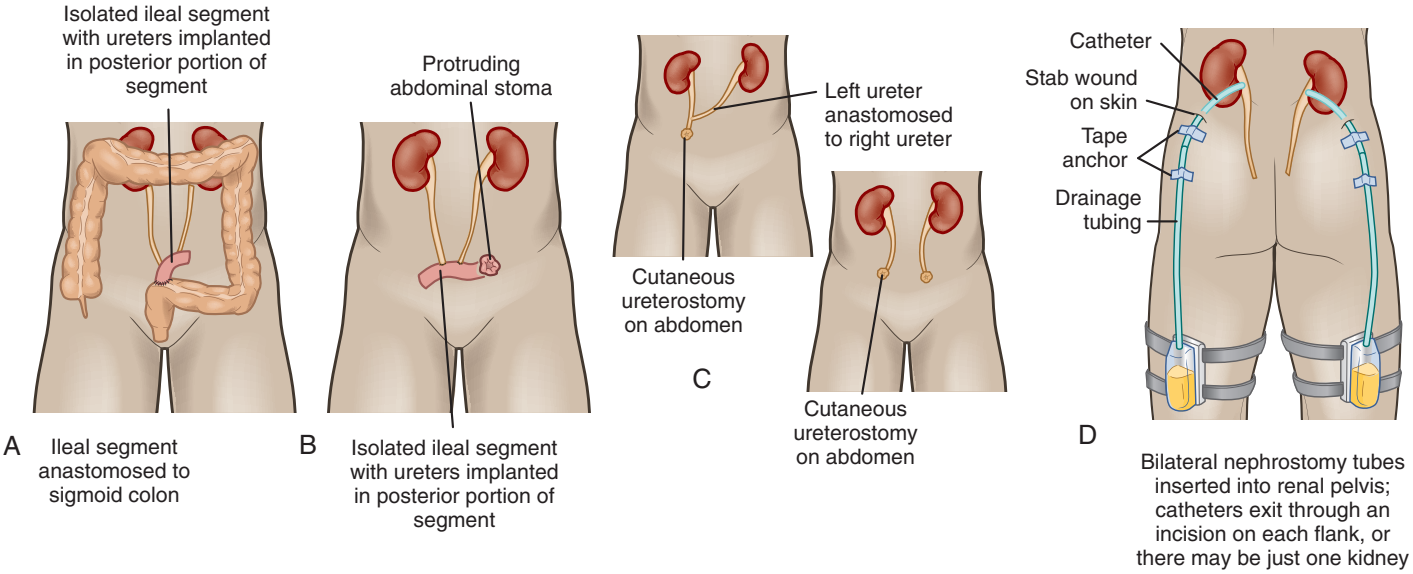

FIG. 46-11 Methods of urinary diversion. **A,** Ureteroileosigmoidostomy. **B,** Ileal loop (ileal conduit). **C,** Ureterostomy (transcutaneous ureterostomy and bilateral cutaneous ureterostomies). **D,** Nephrostomy.

FIG. 46-12 Urinary stoma. Symmetric, no skin breakdown, protrudes about 1.5 cm. Mucosa is healthy red. This configuration is flat when the patient is upright or supine.

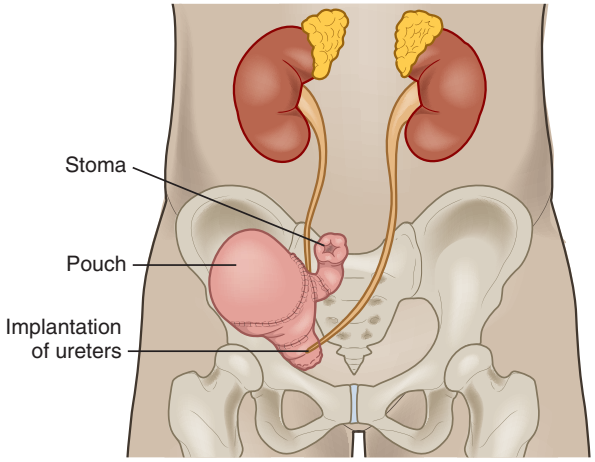

FIG. 46-13 Creation of a Kock pouch with implantation of ureters into one intussuscepted portion of the pouch and creation of a stoma with the other intussuscepted portion.

bowel used. For example, the Indiana pouch uses the right colon as a reservoir and has become a popular form of continent urinary diversion.

Orthotopic Bladder Reconstruction

Orthotopic bladder reconstruction, or orthotopic neobladder, is the construction of a new bladder in the bladder's normal anatomic position, with discharge of urine through the urethra. The reconstruction or neobladder can be derived from various segments of the intestines to create a low-pressure reservoir. An isolated segment of the distal ileum is often preferred. Various procedures include the hemi-Kock pouch, the Studer pouch, and the W-shaped ileoneobladder. In these procedures the bowel is surgically reshaped to become a neobladder. The ureters and urethra are sutured into the neobladder.

Orthotopic bladder reconstruction has become a more viable option for both men and women if cancer does not involve the bladder neck or urethra. Ideal candidates for this procedure have normal renal and liver function, longer than 1- to 2-year life expectancy, adequate motor skills, and no history of inflammatory bowel disease or colon cancer. Obese patients and those with inflammatory bowel disease are not good candidates for this procedure. The advantage of orthotopic bladder substitution is that it allows for natural micturition. Incontinence is a possible problem with this technique, and intermittent catheterization may be required.

NURSING MANAGEMENT URINARY DIVERSION

PREOPERATIVE MANAGEMENT

Teaching is important for the patient awaiting cystectomy and urinary diversion surgery. Assess the patient's ability and readiness to learn before initiating a teaching program. If the patient is not ready to learn, modify the teaching plan. The patient's anxiety and fear may be decreased by providing more information. However, the anxiety and fear may also interfere with learning. Involve the patient's caregiver and family in the teaching process.

Discuss the psychosocial aspects of living with a stoma (including clothing, changes in body image and sexuality, exercise, and odor). This may allay some fears. Teach the patient with a continent diversion (e.g., Indiana pouch) to catheterize at least every 6 hours and irrigate the pouch daily. The patient with an orthotopic neobladder may have problems with incontinence. Discuss the patient's concerns about sexual activities. A wound, ostomy, and continence (WOC) nurse should be involved in the preoperative phase of the patient's care. A visit from an ostomate or WOC nurse can be helpful. Additional interventions are presented in eNursing Care Plan 46-3 for the patient with an ileal conduit (on the website for this chapter).

POSTOPERATIVE MANAGEMENT

Plan the nursing interventions during the postoperative period (see eNursing Care Plan 46-3 for care after an ileal conduit) to prevent surgical complications such as postoperative atelectasis and shock (see Chapter 20). After pelvic surgery, there is an increased incidence of thrombophlebitis, small bowel obstruction, and UTI. With removal of part of the bowel, the incidence of paralytic ileus and small bowel obstruction is increased, the patient is kept on NPO status, and a nasogastric tube is necessary for a few days.

Prevent injury to the stoma and maintain urine output. Advise the patient that mucus in the urine is a normal occurrence. The mucus is secreted by the mucosa of the intestine (which is used to create the ileal conduit) in response to the irritating effect of urine. Encourage a high fluid intake to "flush" the ileal conduit or continent diversion.

When an ileal conduit is created, provide meticulous care for the skin around the stoma. Alkaline encrustations with dermatitis may occur when alkaline urine comes in contact with exposed skin (Fig. 46-14). The urine is kept acidic to prevent alkaline encrustations. Other common peristomal skin problems include yeast infections, product allergies, and shearing-effect excoriations. Changing appliances (pouches) is described in Table 46-23. A properly fitting appliance is essential to prevent skin problems. The appliance should be about 0.1 in (0.2 cm) larger than the stoma. It is normal for the stoma to shrink within the first few weeks after surgery.

Patients with a neobladder may have postoperative urinary retention and require catheterization. It may take up to 6 months for them to regain bladder control. Patients empty their neo-

TABLE 46-23 PATIENT & CAREGIVER TEACHING GUIDE

Ileal Conduit Appliances

Include the following instructions when teaching a patient or a caregiver how to change an ileal conduit appliance.

Temporary Appliance

1. Cut hole in pouch to fit over stoma (pouch ⅛ in [3.2 mm] larger than stoma).
2. Remove old pouch.
3. Clean area gently and remove old adhesive.
4. Wash area with warm water.
5. Place wick (rolled-up 4 × 4-in pad) over stoma to keep area dry during rest of procedure.
6. Dry skin around stoma.
7. Apply tincture of benzoin or other skin protectant around stoma to area where pouch will be placed.
8. Apply pouch by first smoothing its edges toward side and lower portion of body.
9. Remove wick and complete application of bag.
10. If patient is usually in bed, apply bag so that it lies toward side of body.
11. If patient is ambulatory, apply bag so that it lies vertically.
12. Connect drainage tubing to pouch.
13. Keep drainage pouch on same side of bed as stoma.

Permanent Appliance*

1. Keep appliance in place for 2-14 days.
2. Change appliance when fluid intake has been restricted for several hours.
3. Sit or stand in front of mirror.
4. Moisten edge of faceplate with adhesive solvent and gently remove.
5. Clean skin with adhesive solvent.
6. Wash skin with warm water (may be done while showering).
7. Dry skin and inspect.
8. Place wick (rolled-up 4 × 4-in pad) over stoma to keep skin free of urine.
9. Apply skin cement to faceplate and skin.
10. Place appliance over stoma.
11. Wash removed appliance with soap and lukewarm water; soak in distilled vinegar; rinse with lukewarm water and air dry.

*Many disposable appliances with self-adhesive backing are used as permanent appliances.

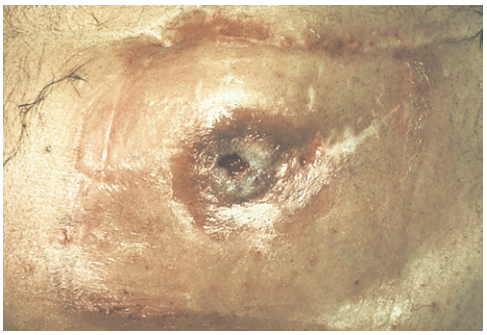

FIG. 46-14 Ammonia salt encrustation secondary to alkaline urine.

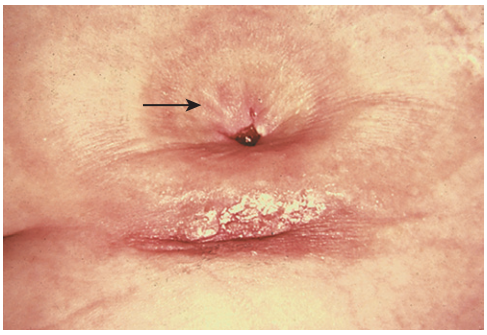

FIG. 46-15 Retracted urinary stoma with pressure sore from faceplate above stoma *(arrow)*.

bladders by relaxing their outlet sphincter muscles and bearing down with their abdominal muscles. Since there is no longer neurologic feedback between the reservoir and the brain, the patient should not expect a normal desire to void. To avoid bladder overdistention, patients should void at least every 2 to 4 hours, sit during voiding, and practice pelvic floor muscle relaxation to aid voiding. Follow-up x-ray studies include a "pouchogram" 3 to 4 weeks after surgery to assess for healing.

Acceptance of the surgery and of alterations in body image is needed to ensure the patient's best adjustment. Meeting and sharing feelings with similar patients can enhance a patient's adjustment to a urinary diversion. Patient concerns include fear that the stoma will be offensive to others and will interfere with sexual, personal, professional, and recreational activities. Advise the patient that few activities will be restricted as a result of the urinary diversion.

Discharge planning after an ileal conduit includes teaching the patient symptoms of obstruction or infection and care of the ostomy. The patient with an ileal conduit is fitted for a permanent appliance 7 to 10 days after surgery and may need to be refitted at a later time, depending on the degree of stoma healing and shrinkage.

Appliances are made of a variety of products, including natural and synthetic rubbers, plastics, and metals. Most appliances have a faceplate that adheres to the skin, a collecting pouch, and an opening to drain the pouch. The faceplate may be secured to the skin with glues, adhesives, or adherent synthetic wafers. Some appliances do not require adhesives, but their design relies on pressure to keep the pouch in place. If improperly fitted or applied, the faceplate may cause skin problems (Fig. 46-15). Inform the patient and caregiver about where to purchase supplies, emergency telephone numbers, location of ostomy clubs, and follow-up visits with a WOC nurse. Physician follow-up is imperative to monitor the patient's recovery, detect any complications, and assess renal function.

CASE STUDY

Urinary Tract Infection

iStockphoto/Thinkstock

Patient Profile

S.U., a 38-yr-old Hispanic woman, was seen in the nurse practitioner's office for a history of painful, frequent urination.

Subjective Data

- Has a history of painful, frequent urination with passage of small volumes of urine for 3 days
- Had intermittent fever, chills, and back pain during these 3 days
- Was frightened when she saw blood in her urine
- Reports this is her third attack of painful urination and back pain in 4 mo
- Is anxious because her father died of kidney cancer
- Remembers having many UTIs as a child
- Has had four pregnancies with difficult vaginal deliveries

Objective Data

Physical Examination

- Complains of bilateral flank pain and abdominal tenderness to palpation
- Temperature is 100.4° F (38° C)

Diagnostic Studies

- Urinalysis: pyuria and hematuria
- Follow-up studies to be done

Discussion Questions

1. What are the most common organisms that cause UTIs?
2. What additional information do you or the nurse practitioner need from S.U.?
3. What factors predispose a patient to a UTI?
4. What is the difference between upper and lower UTIs?
5. ***Priority Decision:*** What are the priority nursing interventions for S.U.?
6. Why might S.U. be having recurrent bouts of UTIs? What other diagnostic tests may be indicated?
7. ***Evidence-Based Practice***: S.U. wants to know what she can do to prevent another UTI. What are you going to tell her?
8. ***Priority Decision:*** Based on the data presented, write one or more appropriate nursing diagnoses. Are there any collaborative problems?

evolve Answers available at *http://evolve.elsevier.com/Lewis/medsurg*.

BRIDGE TO NCLEX EXAMINATION

The number of the question corresponds to the same-numbered outcome at the beginning of the chapter.

1. In teaching a patient with pyelonephritis about the disorder, the nurse informs the patient that the organisms that cause pyelonephritis most commonly reach the kidneys through
   a. the bloodstream.
   b. the lymphatic system.
   c. a descending infection.
   d. an ascending infection.
2. The nurse teaches the female patient who has frequent UTIs that she should
   a. take tub baths with bubble bath.
   b. urinate before and after sexual intercourse.
   c. take prophylactic sulfonamides for the rest of her life.
   d. restrict fluid intake to prevent the need for frequent voiding.
3. The immunologic mechanisms involved in acute poststreptococcal glomerulonephritis include
   a. tubular blocking by precipitates of bacteria and antibody reactions.
   b. deposition of immune complexes and complement along the GBM.
   c. thickening of the GBM from autoimmune microangiopathic changes.
   d. destruction of glomeruli by proteolytic enzymes contained in the GBM.
4. One of the nurse's most important roles in relation to acute poststreptococcal glomerulonephritis is to
   a. promote early diagnosis and treatment of sore throats and skin lesions.
   b. encourage patients to obtain antibiotic therapy for upper respiratory tract infections.
   c. teach patients with APSGN that long-term prophylactic antibiotic therapy is necessary to prevent recurrence.
   d. monitor patients for respiratory symptoms that indicate the disease is affecting the alveolar basement membrane.
5. The edema that occurs in nephrotic syndrome is due to
   a. increased hydrostatic pressure caused by sodium retention.
   b. decreased aldosterone secretion from adrenal insufficiency.
   c. increased fluid retention caused by decreased glomerular filtration.
   d. decreased colloidal osmotic pressure caused by loss of serum albumin.
6. A patient is admitted to the hospital with severe renal colic. The nurse's first priority in management of the patient is to
   a. administer opioids as prescribed.
   b. obtain supplies for straining all urine.
   c. encourage fluid intake of 3 to 4 L/day.
   d. keep the patient NPO in preparation for surgery.
7. The nurse recommends genetic counseling for the children of a patient with
   a. nephrotic syndrome.
   b. chronic pyelonephritis.
   c. malignant nephrosclerosis.
   d. adult-onset polycystic kidney disease.
8. The nurse identifies a risk factor for kidney and bladder cancer in a patient who relates a history of
   a. aspirin use.
   b. tobacco use.
   c. chronic alcohol abuse.
   d. use of artificial sweeteners.
9. In planning nursing interventions to increase bladder control in the patient with urinary incontinence, the nurse includes
   a. teaching the patient to use Kegel exercises.
   b. clamping and releasing a catheter to increase bladder tone.
   c. teaching the patient biofeedback mechanisms to suppress the urge to void.
   d. counseling the patient concerning choice of incontinence containment device.
10. A patient with a ureterolithotomy returns from surgery with a nephrostomy tube in place. Postoperative nursing care of the patient includes
    a. encouraging the patient to drink fruit juices and milk.
    b. encouraging fluids of at least 2 to 3 L/day after nausea has subsided.
    c. irrigating the nephrostomy tube with 10 mL of normal saline solution as needed.
    d. notifying the physician if nephrostomy tube drainage is more than 30 mL/hr.
11. A patient has had a cystectomy and ileal conduit diversion performed. Four days postoperatively, mucous shreds are seen in the drainage bag. The nurse should
    a. notify the physician.
    b. notify the charge nurse.
    c. irrigate the drainage tube.
    d. chart it as a normal observation.

1. d, 2. b, 3. b, 4. a, 5. d, 6. a, 7. d, 8. b, 9. a, 10. b, 11. d

LEARNING OUTCOMES

1. Differentiate between acute kidney injury and chronic kidney disease.
2. Identify criteria used in the classification of acute kidney injury using the acronym RIFLE (*R*isk, *I*njury, *F*ailure, *L*oss, *E*nd-stage kidney disease).
3. Describe the clinical course of acute kidney injury.
4. Explain the collaborative care and nursing management of a patient with acute kidney injury.
5. Define *chronic kidney disease* and delineate its five stages based on the glomerular filtration rate.
6. Select risk factors that contribute to the development of chronic kidney disease.
7. Summarize the significance of cardiovascular disease in individuals with chronic kidney disease.
8. Explain the conservative collaborative care for and the related nursing management of the patient with chronic kidney disease.
9. Differentiate among renal replacement therapy options for individuals with end-stage kidney disease.
10. Compare and contrast nursing interventions for individuals on peritoneal dialysis and hemodialysis.
11. Discuss the role of nurses in the management of individuals who receive a kidney transplant.

KEY TERMS

acute kidney injury (AKI), p. 1101
acute tubular necrosis (ATN), p. 1103
arteriovenous fistula (AVF), p. 1120
arteriovenous grafts (AVGs), p. 1120
automated peritoneal dialysis (APD), p. 1119
azotemia, p. 1102
chronic kidney disease (CKD), p. 1107
CKD mineral and bone disorder (CKD-MBD), p. 1110
continuous ambulatory peritoneal dialysis (CAPD), p. 1119
continuous renal replacement therapy (CRRT), p. 1123
dialysis, p. 1117
end-stage kidney (renal) disease (ESKD), p. 1107
hemodialysis (HD), p. 1117
oliguria, p. 1103
peritoneal dialysis (PD), p. 1117
uremia, p. 1108

Kidney failure (also called *renal failure*) is the partial or complete impairment of kidney function. It results in an inability to excrete metabolic waste products and water, and it contributes to disturbances of all body systems. Kidney disease can be classified as acute or chronic (Table 47-1). Acute kidney injury (AKI) has a rapid onset. Chronic kidney disease (CKD) is linked with the development of cardiovascular (CV) disease.

ACUTE KIDNEY INJURY

Acute kidney injury (AKI), previously known as *acute kidney failure,* is the term used to encompass the entire range of the syndrome, ranging from a slight deterioration in kidney function to severe impairment. AKI is characterized by a rapid loss of kidney function. This loss is accompanied by a rise in serum

creatinine and/or a reduction in urine output. The severity of dysfunction can range from a small increase in serum creatinine or reduction in urine output to the development of **azotemia** (an accumulation of nitrogenous waste products [urea nitrogen, creatinine] in the blood).

Although AKI is potentially reversible, it has a high mortality rate.[1] AKI usually affects people with other life-threatening conditions[2] (Table 47-2). Most commonly, AKI follows severe, prolonged hypotension or hypovolemia or exposure to a nephrotoxic agent.

AKI can develop over hours or days with progressive elevations of blood urea nitrogen (BUN), creatinine, and potassium with or without a reduction in urine output. Hospitalized patients develop AKI at a high rate (1 in 5) and have a high mortality rate. When AKI develops in patients in intensive care units (ICUs), the mortality rate can be as high as 70% to 80%.[3-5]

TABLE 47-1 COMPARISON OF ACUTE KIDNEY INJURY AND CHRONIC KIDNEY DISEASE

	Acute Kidney Injury	Chronic Kidney Disease
Onset	Sudden	Gradual, often over many years
Most common cause	Acute tubular necrosis	Diabetic nephropathy
Diagnostic criteria	Acute reduction in urine output and/or Elevation in serum creatinine	GFR <60 mL/min/1.73m^2 for >3 mo and/or Kidney damage >3 mo
Reversibility	Potentially	Progressive and irreversible
Primary cause of death	Infection	Cardiovascular disease

GFR, Glomerular filtration rate.

Etiology and Pathophysiology

The causes of AKI, which are multiple and complex, are categorized as prerenal, intrarenal (or intrinsic), and postrenal causes (see Table 47-2).

Prerenal. *Prerenal* causes of AKI are factors external to the kidneys. These factors reduce systemic circulation, causing a reduction in renal blood flow. The decrease in blood flow leads to decreased glomerular perfusion and filtration of the kidneys. Although kidney tubular and glomerular function is preserved, glomerular filtration is reduced as a result of decreased perfusion.

It is important to distinguish prerenal oliguria from the oliguria of intrarenal AKI. In prerenal oliguria there is no damage to the kidney tissue (parenchyma). The oliguria is caused by a decrease in circulating blood volume (e.g., severe dehydration, heart failure [HF], decreased cardiac output) and is readily reversible with appropriate treatment. With a decrease in circulating blood volume, autoregulatory mechanisms that increase angiotensin II, aldosterone, norepinephrine, and antidiuretic hormone attempt to preserve blood flow to essential organs. Prerenal azotemia results in a reduction in the excretion of sodium (less than 20 mEq/L), increased sodium and water retention, and decreased urine output.

Prerenal conditions can lead to intrarenal disease if renal ischemia is prolonged. Prerenal conditions account for many cases of intrarenal AKI. If decreased perfusion persists for an extended time, the kidneys lose their ability to compensate and damage to kidney parenchyma occurs (intrarenal damage).

Intrarenal. *Intrarenal* causes of AKI (see Table 47-2) include conditions that cause direct damage to the kidney tissue, resulting in impaired nephron function. The damage from intrarenal causes usually results from prolonged ischemia, nephrotoxins

TABLE 47-2 COMMON CAUSES OF ACUTE KIDNEY INJURY

Prerenal

Hypovolemia
- Dehydration
- Hemorrhage
- GI losses (diarrhea, vomiting)
- Excessive diuresis
- Hypoalbuminemia
- Burns

Decreased Cardiac Output
- Cardiac dysrhythmias
- Cardiogenic shock
- Heart failure
- Myocardial infarction

Decreased Peripheral Vascular Resistance
- Anaphylaxis
- Neurologic injury
- Septic shock

Decreased Renovascular Blood Flow
- Bilateral renal vein thrombosis
- Embolism
- Hepatorenal syndrome
- Renal artery thrombosis

Intrarenal

Nephrotoxic Injury
- Drugs: aminoglycosides (gentamicin, amikacin), amphotericin B
- Contrast media
- Hemolytic blood transfusion reaction
- Severe crush injury
- Chemical exposure: ethylene glycol, lead, arsenic, carbon tetrachloride

Interstitial Nephritis
- Allergies: antibiotics (sulfonamides, rifampin), nonsteroidal antiinflammatory drugs, ACE inhibitors
- Infections: bacterial (acute pyelonephritis), viral (CMV), fungal (candidiasis)

Other Causes
- Prolonged prerenal ischemia
- Acute glomerulonephritis
- Thrombotic disorders
- Toxemia of pregnancy
- Malignant hypertension
- Systemic lupus erythematosus

Postrenal
- Benign prostatic hyperplasia
- Bladder cancer
- Calculi formation
- Neuromuscular disorders
- Prostate cancer
- Spinal cord disease
- Strictures
- Trauma (back, pelvis, perineum)

ACE, Angiotensin-converting enzyme; *CMV,* cytomegalovirus.

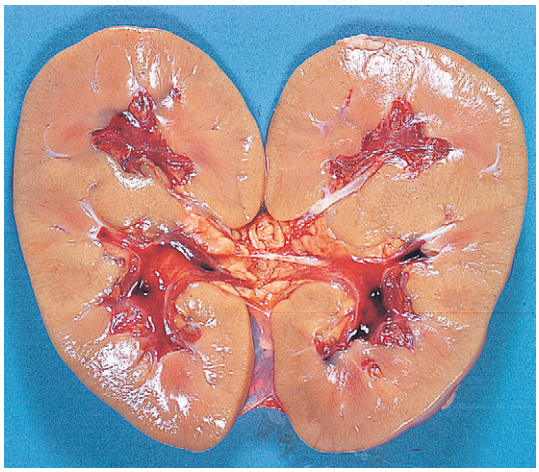

FIG. 47-1 Acute tubular necrosis. The kidneys are swollen and pale.

(e.g., aminoglycoside antibiotics, contrast media), hemoglobin released from hemolyzed red blood cells (RBCs), or myoglobin released from necrotic muscle cells.

Nephrotoxins can cause obstruction of intrarenal structures by crystallizing or by causing damage to the epithelial cells of the tubules. Hemoglobin and myoglobin can block the tubules and cause renal vasoconstriction. Diseases of the kidney such as acute glomerulonephritis and systemic lupus erythematosus may also cause AKI.

Acute tubular necrosis (ATN) is the most common intrarenal cause of AKI and is primarily the result of ischemia, nephrotoxins, or sepsis (Fig. 47-1). Ischemic and nephrotoxic ATN is responsible for 90% of intrarenal AKI cases.[6,7] Severe kidney ischemia causes a disruption in the basement membrane and patchy destruction of the tubular epithelium. Nephrotoxic agents cause necrosis of tubular epithelial cells, which slough off and plug the tubules. ATN is potentially reversible if the basement membrane is not destroyed and the tubular epithelium regenerates.

ATN is the most common cause of AKI for hospitalized patients. Risks associated with development of ATN while in the hospital include major surgery, shock, sepsis, blood transfusion reaction, muscle injury from trauma, prolonged hypotension, and nephrotoxic agents (see Table 47-2).

Postrenal. *Postrenal* causes of AKI involve mechanical obstruction in the outflow of urine. As the flow of urine is obstructed, urine refluxes into the renal pelvis, impairing kidney function. The most common causes are benign prostatic hyperplasia, prostate cancer, calculi, trauma, and extrarenal tumors. Bilateral ureteral obstruction leads to *hydronephrosis* (kidney dilation), increase in hydrostatic pressure, and tubular blockage, resulting in a progressive decline in kidney function. If bilateral obstruction is relieved within 48 hours of onset, complete recovery is likely. After 12 weeks, recovery is unlikely. Prolonged obstruction can lead to tubular atrophy and irreversible kidney fibrosis. Postrenal causes of AKI account for less than 10% of AKI cases.[7,8]

Clinical Manifestations

Prerenal and postrenal AKI that has not caused intrarenal damage usually resolves quickly with treatment of the cause. However, when parenchymal damage occurs due to either prerenal or postrenal causes, or when parenchymal damage occurs directly as with intrarenal causes, AKI has a prolonged course.

TABLE 47-3 RIFLE CLASSIFICATION FOR STAGING ACUTE KIDNEY INJURY

Stage	GFR Criteria	Urine Output Criteria
Risk	Serum creatinine increased × 1.5 OR GFR decreased by 25%	Urine output <0.5 mL/kg/hr for 6 hr
Injury	Serum creatinine increased × 2 OR GFR decreased by 50%	Urine output <0.5 mL/kg/hr for 12 hr
Failure	Serum creatinine increased × 3 OR GFR decreased by 75% OR Serum creatinine >4 mg/dL with acute rise ≥0.5 mg/dL	Urine output <0.3 mL/kg/hr for 24 hr (oliguria) OR Anuria for 12 hr
Loss	Persistent acute kidney failure; complete loss of kidney function >4 wk	—
End-stage kidney disease	Complete loss of kidney function >3 mo	—

GFR, Glomerular filtration rate.

Clinically, AKI may progress through phases: oliguric, diuretic, and recovery. When a patient does not recover from AKI, then CKD may develop.

The RIFLE classification is used to describe the stages of AKI (Table 47-3). *R*isk, the first stage of AKI, is followed by *I*njury, which is the second stage. Then AKI increases in severity to the final or third stage, *F*ailure. The two outcome variables are *L*oss and *E*nd-stage kidney disease. (See eTable 47-2 for a case study showing how RIFLE classification is used.)

Oliguric Phase. Manifestations of AKI are presented in eTable 47-1 (available on the website for this chapter). The most common manifestations are discussed in this section.

Urinary Changes. The most common initial manifestation of AKI is **oliguria,** a reduction in urine output to less than 400 mL/day. Nonoliguria AKI indicates a urine output greater than 400 mL/day. Oliguria usually occurs within 1 to 7 days of the injury to the kidneys. If the cause is ischemia, oliguria often occurs within 24 hours. In contrast, when nephrotoxic drugs are involved, the onset may be delayed for as long as 1 week. The oliguric phase lasts on average about 10 to 14 days but can last months in some cases. The longer the oliguric phase lasts, the poorer the prognosis for complete recovery of kidney function.[1]

About 50% of patients will not be oliguric, making the initial diagnosis more difficult.[5] Changes in urine output generally do not correspond to changes in glomerular filtration rate (GFR). However, changes in urine output are often helpful in differentiating the etiology of AKI. For example, anuria is usually seen with urinary tract obstruction, oliguria is commonly seen with prerenal etiologies, and nonoliguric AKI is seen with acute interstitial nephritis and ATN.[8]

A urinalysis may show casts, RBCs, and white blood cells (WBCs). The casts are formed from mucoprotein impressions of the necrotic renal tubular epithelial cells, which detach or slough into the tubules. In addition, a urinalysis may show a specific gravity fixed at around 1.010 and urine osmolality at about 300 mOsm/kg (300 mmol/kg). This is the same specific gravity and osmolality of plasma, thus reflecting tubular damage

with a loss of concentrating ability by the kidney. Proteinuria may be present if kidney failure is related to glomerular membrane dysfunction.

Fluid Volume. Hypovolemia (volume depletion) has the potential to exacerbate all forms of AKI. The reversal of hypovolemia with fluid replacement is often sufficient to treat many forms of AKI, especially prerenal causes.

When urine output decreases, fluid retention occurs. The severity of the symptoms depends on the extent of the fluid overload. In the case of reduced urine output (anuria and oliguria), the neck veins may become distended with a bounding pulse. Edema and hypertension may develop. Fluid overload can eventually lead to HF, pulmonary edema, and pericardial and pleural effusions.

Metabolic Acidosis. In kidney failure the kidneys cannot synthesize ammonia (needed for hydrogen ion excretion) or excrete acid products of metabolism. The serum bicarbonate level decreases because bicarbonate is depleted in buffering hydrogen ions. In addition, defective reabsorption and regeneration of bicarbonate occur. With development of severe acidosis, the patient may develop Kussmaul respirations (rapid, deep respirations) in an effort to compensate by increasing the exhalation of carbon dioxide.

Sodium Balance. Damaged tubules cannot conserve sodium. Consequently, the urinary excretion of sodium may increase, resulting in normal or below-normal levels of serum sodium. Excessive intake of sodium should be avoided because it can lead to volume expansion, hypertension, and HF. Uncontrolled hyponatremia or water excess can lead to cerebral edema.

Potassium Excess. The kidneys normally excrete 80% to 90% of the body's potassium. In AKI the serum potassium level increases because the kidney's normal ability to excrete potassium is impaired. Hyperkalemia is more of a risk if AKI is caused by massive tissue trauma because the damaged cells release additional potassium into the extracellular fluid. Additionally, bleeding and blood transfusions may cause cellular destruction, releasing more potassium into the extracellular fluid. Last, acidosis worsens hyperkalemia as hydrogen ions enter the cells and potassium is driven out of the cells into the extracellular fluid.

Even though patients with hyperkalemia are usually asymptomatic, some patients may complain of weakness with severe hyperkalemia. Acute or rapid development of hyperkalemia may result in clinical signs that are apparent on electrocardiogram (ECG). These changes include peaked T waves, widening of the QRS complex, and ST segment depression. Progressive changes in the ECG that are related to increasing potassium levels are depicted in Fig. 17-14. Because cardiac muscle is intolerant of acute increases in potassium, treatment is essential whenever hyperkalemia develops.[9]

Hematologic Disorders. Several hematologic disorders are seen in patients with AKI. Hospital-acquired AKI often occurs in patients who have multiorgan failure. Leukocytosis is often present with AKI. The most common cause of death in AKI is infection. The most common sites of infection are the urinary and respiratory systems. A complete blood count with evidence of eosinophilia suggests an allergic response and possibly interstitial nephritis, polyarteritis nodosa, or atheroemboli.
